EMIR.—An Arabic word, equivalent to "Ruler;" it is a title given in the East, and in the North of Africa, to all independent Chieftains, and also to all the actual or supposed descendants of Mohammed through his daughter Fatima. The latter are very numerous throughout the Turkish dominions; but although entitled by birth to be classed among the first four orders of society, they enjoy no particular privileges or consideration; on the contrary, they are found engaged in all sorts of occupations, and are to be met with among beggars, and the lowest of the populace, as frequently as among the Mollahs. Their privileges are confined to a few unimportant matters, chiefly to the exclusive right to wear turbans of a green color, that having been the favorite color of the Prophet. They are placed under the supervision of the Emir-Beshir. In former times the title of Emir was borne by the leaders in the religious wars of the Mohammedans, as well as by several ruling families, such as the Thaherides and Samanides in Persia, the Tulunides in Egypt, the first seven Ommaiades in Spain. The title Emir, in connection with other words, likewise designates different offices. *Emir-al-Mumenin*, "Prince of the Faithful," is the title assumed by the Caliphs themselves; *Emir-al-Muslemin*, signifying the same thing, was the title of the Almoravides. *Emir-al-Omrah*, "Prince of Princes," was the title of the first Minister, under the Caliphs and the East Indian Moguls, who united in his own person the highest civil and military dignities. It is now the title of the Governors of different Provinces. The Turkish Master of the Horse is styled *Emir-Achor;* the Standard-bearer, *Emir-Alem;* and the leader of the caravans of pilgrims to Mecca, *Emir-Hadji. Ameer* or *Amere* is another spelling of the same word.

EMISSARY.—A spy, a scout. In a military sense, one who during war-time personates the dress, language, and character of the power or nation he is sent amongst for the purpose of obtaining information, or for the purpose of creating disaffection in the ranks of the enemy.

EMOLUMENT.—The profit arising from office or employment; that which is received as a compensation for services, or which is annexed to the possession of office, as salary, fees, and perquisites. See *Pay.*

EMOUSSER.—To blunt, to dull. In a military sense, the word signifies, to take off the four corners of a battalion which has formed a square, and to give it, by those means, an octagonal figure; from the different obtuse angles of which it may fire in all directions.

EMPEROR.—The original signification of this, which in the modern world has become the highest title of sovereignty, can be understood only when it is taken in conjunction with *imperium*, which in the Roman political system had a peculiar and somewhat technical meaning. The imperium of a Magistrate, be he King or Consul, was the power which he possessed of bringing physical force into operation for the fulfillment of his behests. This power was conferred by a *Lex Curiata*, and it required this authorization to entitle a Consul to act as the Commander of an Army. In the case of the Kings also, the imperium was not implied in their election, but was conferred separately, by a separate act of the national will. "On the death of King Pompilius," says Cicero, "the *populus* in the *comitia curiata* elected Tullus Hostilius King, upon the rogation of an *interrex;* and the King, following the example of Pompilius, took the votes of the *populus*, according to their *curiæ, on the question of his imperium.*" Now, it was in virtue of this imperium that the title Imperator was given to its possessor. Far from being an Emperor in the modern sense, he might be a Consul or a Proconsul; and there were, in fact, many Imperators, even after the title had been assumed as a prenomen by Julius Cæsar. It was this assumption which gradually gave to the title its modern signification. In republican times it had followed the name, and indicated simply that its possessor was *an* Imperator, or one possessed of the imperium; now it preceded it, and signified that he who arrogated it to himself was *the* Emperor. In this form it appears on the coins of the successors of Julius. After the times of the Antonines the title grew into use as expressing the possessor of the sovereignty of the Roman world, in which sense *Princeps* also was frequently employed. In the introduction to the *Institutes*, Justinian uses both, in speaking of himself, in the same paragraph. From the Emperors of the West the title passed to Charlemagne, the founder of the German Empire. When the Carlovingian family expired in the German branch, the Imperial crown became elective, and continued to be so till it ceased—Francis II., who in 1804 had declared himself hereditary Emperor of Austria, having laid it down in 1806. In addition to the Emperor of Austria, there are now in Europe the Emperor of Russia and Emperor of Germany, the latter of whom was, on January 18, 1871, proclaimed under this title within the Hall of Mirrors, in the Palace of the French Kings at Versailles, in the presence of the German Princes, and the standards of the German army which was beleaguering Paris. In 1876 the Queen of England assumed the title of Empress of India, in addition to those which she bore previously.

EMPILEMENT.—The act of disposing shot and shell in the most secure and convenient manner. This is always done in arsenals and citadels.

EMPRISE.—A hazardous attempt upon the enemy. See *Enfans Perdus* and *Forlorn Hope*.

EMPTY BASTION.—When the rampart, following the outline of the crest of the bastion, has in its center an interior space on the level of the ground, the bastion is called *empty* or *hollow*.

ENCAMPMENT.—A lodgment or home for soldiers in the field. There are *intrenched* camps, where an army is intended to be kept some time, protected against the enemy; *flying* camps, for brief occupation; camps of *position*, bearing relation to the strategy of the Commander; and camps of *instruction*, to habituate the troops to the duties and fatigues of war. Under Camp has been given an account of the manner in which Roman camps were constructed. It is probable that the same general plan was adhered to until the invention of gunpowder. When cannon came to be used, however, a new arrangement of camp became necessary, to shield the army from long-range projectiles. Everything, indeed, relating to attack and defense, especially to the latter, is taken into account in chosing the locality of a camp. A healthy site, good water, security from floods, and plenty of fuel and forage, are the chief requisites in a good encampment. The British army, when in the field, usually encamps by brigades or divisions, roads and paths being arranged before the troops arrive. The infantry, cavalry, and artillery are so placed as to defend each other in the event of a sudden attack. There is a chain of guards all round the spot; and the park of artillery is placed behind the troops. The sutlers and servants are in the rear of the camp, but not beyond the limits of the rear-guard. The tents of the infantry are ranged in rows perpendicular to the front, each row containing the tents for one company. The circular tents, now much used, accommodate fifteen men each. The cavalry are in like manner encamped in rows; but each circular tent accommodates only twelve men. There are streets or roads between the rows of tents, of regulated width; and the officers' tents are at a given distance behind those of the men: the subalterns' tents being nearest to those of the companies to which they respectively belong. As a general rule, the line of the whole encampment is made to correspond as nearly as practicable with that in which the troops are intended to engage the enemy when fighting is renewed; to which end the tents of each battalion are not allowed to occupy a greater space in front than the battalion itself would cover when in order of battle. Under most circumstances, in modern warfare, an encampment is not defended by artificial constructions; the Commander seeks security for his troops in streams, marshes, difficult surface of country, and numerous advanced posts. Sometimes, however, more extensive defense-works are necessary; and then we have an example of an *intrenched* camp, which becomes a fortified inclosure. The chief uses of such a camp are, to secure an army while covering a siege, or, in winter quarters, to accommodate a Corps of Observation while the active army is engaged elsewhere; or to defend a position near a fortified place. Care is taken that the site is not commanded by neighboring hills. All villages are occupied, and all obstacles removed, within a distance of half a mile or a mile. The area of ground selected is large enough to contain the necessary store of arms, ammunition, food, fuel, forage, and water, and to enable the troops to maneuver. The junction of two rivers is often selected as a favorable spot. Various defense-works are constructed around or near the spot, such as continuous earthworks, redoubts, flèches, etc. The position held by the Allies outside Sebastopol, during the long intervals when the cannonading was suspended, had many of the characteristics of an intrenched camp. Camps of *instruction* may be either temporary or permanent. Of the former kind was the camp formed at Chobham in Surrey in 1853, merely for the summer months, to exercise certain regiments in evolutions. Another was formed at Shorncliffe in Kent in 1855, at first to receive troops of the Foreign Legion; but it has since been improved to the condition of a permanent camp. The great establishment at Aldershott has been, by an ungrudging outlay of public funds, improved in all particulars, and the small agricultural village of Aldershott has grown into an important commercial town, with railway-stations, hotels, market-houses, handsome shops, etc. A large permanent camp has also been established in Ireland, on a plain called the Curragh of Kildare, and there is a smaller one at Colchester. See *Camp*, *Castrametation*, and *Field-service*.

ENCEINTE.—The best mode of arranging the elements of a defense requires that the work should be so planned that every point exterior to the defenses within cannon-range should be thoroughly swept by their fire. Owing to the form and height of the parapet, its fire can take effect only at some distance beyond it. The enemy having reached the ditch will not be exposed to fire unless some arrangement has been made to sweep the ditch. Any place where he can find shelter, where the missiles of the defense pass so high above him as to inflict no injury, is called a *dead-angle* or *dead-space*. To remove this defect, the main work may be so arranged as to sweep by its fire every point exterior to it, or auxiliary works termed caponieres, scarp and counterscarp galleries, etc., may be used. In the former case parts of the work must be thrown forward towards the enemy and other portions retired. These advanced parts are called *faces;* the retired parts, *flanks;* and the parts connecting the flanks, *curtains*. The outline of such a plan must be angular. The angular points towards the enemy are called *salients*. The angle formed by two retired parts, a *re-entering* angle. The line bisecting a salient angle is called the *capital*. In firing over a parapet, a soldier usually aims directly to the front, so that the line of fire and the parapet make nearly a right angle with each other. There is then an angular space in front of the salient (equal to the supplement of the salient angle) which receives no protection by direct fire from it. This space is termed a *sector without fire*. The continuous line of fortification inclosing a position is called the enceinte, the *body of the place* or the *main inclosure*. The general outline of the enceinte may be *curvilinear*, or a *polygonal figure* of any character. Whatever system may be adopted for the enceinte, there are some conditions which it must satisfy to render it effective: 1. It should have a steep revetted scarp; unbroken on all sides except for the necessary openings for communications; thoroughly flanked throughout by cannon and small-arms; and of sufficient height to prevent all ordinary attempts at escalade. 2. The scarp should be so covered by earthen or other masks that it cannot be reached by the projectiles of an assailant from any position exterior to these masks. 3. The parapet and interior covered shelters should be proof against solid and hollow loaded projectiles. 4. The parapet should command all the site and outworks exterior to the enceinte and within range of its guns, and sweep them with flank and cross fires. 5. As far as practicable, the principal lines of the parapet should receive such directions that the assailant cannot take up positions to enfilade them. If the position thus inclosed be an inhabited one, as a city, town, etc., or an important point that requires the presence of other persons than those necessary for its defense, it receives the name of *fortress*, or *fortified place*. If it is destined to receive no other inhabitants but the troops for its defense, it is called a *fort;* and the defenders are termed the *garrison*.

ENCOMBRER.—In fortification, to fill up any hollow place, such as a stagnant lake, etc., with rubbish.

ENCOUNTER.—Literally, a combat or fight between two persons. It is not unfrequently used to describe a battle or attack by large or small bodies of troops.

ENDORSE.—In Heraldry, an ordinary containing the fourth part of a pale. *Endorsed*, again, or *indorsed*, signifies that objects are placed on the shield back to back. See *Heraldry*.

ENDURANCE OF GUNS.—The principal injuries caused by service are internal, arising from the separate action of the powder and the projectile. They increase in extent with the caliber, whatever may be the nature of the gun, but are modified by the material of which it is made. The injuries from the powder generally occur in rear of the projectile. They are: 1st. Enlargement of that portion of the bore which contains the powder, arising from the compression of the metal. This injury is more marked when a sabot or wad is placed between the powder and the projectile, and is greatest in a vertical direction. 2d. Cavities produced by the melting away of a portion of the metal by the heat of combustion of the charge. 3d. Cracks arising from the tearing asunder of the particles of the metal at the surface of the bore. At first a crack of this kind is scarcely perceptible, but it is increased by continued firing until it extends completely through the side of the piece. It generally commences at the junction of the chamber with the bore, as this portion is less supported than the others. 4th. Furrows or scoring produced by the erosive action of the inflamed gases. This injury is most apparent where the current of the gas is most rapid, or at the interior orifice of the vent, and on the surface of the bore, immediately over the seat of the projectile. *Scoring* commences very early in large guns; at first it is only a mere roughness, which gradually increases in depth and forms lines along the bore; but it is not until a gun has been fired very considerably that it becomes of importance. The impressions of deep scoring resemble the bark of an old elm-tree, the metal being eaten away into irregular furrows and ridges. Even when it has reached this extreme case, however, scoring has not caused the destruction of the gun, though in some instances, acting like a wedge, it has split the bore at that part. Some experimental guns, excessively scored on the upper side of the bore, have been turned over, vented and sighted on the under side; but this has not been found necessary until the gun has been used more than is probable under ordinary circumstances.

The injuries arising from the action of the projectile occur around the projectile and in front of it. They are: 1st. Indentation in the lower side of the bore, produced by the pressure on the projectile by the escape of gas through the windage, before the ball has moved from its seat. The elasticity of the metal, and the burr, or crowding up of the metal in front of the projectile, cause it to rebound, and, being carried forward by the force of the charge, to strike against the upper side of the bore, a short distance in front of the trunnions. From this it is reflected against the bottom, and again reflected against the top of the bore, and so on until it leaves the piece. The first is called "indentation," and the others are called "enlargements." In pieces of ordinary length there are generally three enlargements when this injury first makes its appearance, but their number is increased as the "indentation" is depressed and the angle of incidence increased. The effect of this bounding motion is alternately to raise and depress the piece in its trunnion-holes, and to diminish the accuracy of fire, until finally the piece becomes unfit for service. It is principally from this injury that bronze guns become unserviceable. Mortars and howitzers are not much affected by it. The principal means used to prevent this injury are to wrap the projectile with cloth or paper, and to shift the seat of the projectile. The latter may be done by a wad or lengthened sabot, or by reducing the diameter and increasing the length of the cartridge. The last of these methods is considered the more practical as well as the more effective; and it has the additional advantage of decreasing the strain on the bore, by increasing the space in which the charge expands before the ball is moved. 2d. Scratches or furrows made upon the surface of the bore by rough projectiles, or by case-shot. 3d. Cuts made by the fragments of projectiles which break in the bore. 4th. Wearing away of the lands of rifled cannon, especially at the driving-edges. A little rubbing of the side of the grooves from the friction of hard bearings is of little importance. 5th. Enlargement of the muzzle, arising from the forcing outward of the metal by the striking of the projectile against the side of the bore as it leaves the piece. By this action the shape of the muzzle is elongated in a vertical direction. 6th. Cracks on the exterior. These are formed by the compression of the metal within, generally at the *chase*, where the metal is thinnest. This portion of a bronze gun is the first to give way by long firing, whereas cast-iron guns usually burst in rear of the trunnions, and the fracture passes through the vent, if it be much enlarged.

The endurance of a smooth-bore gun with service-charges may be surely predicted by observation of the progressive wear of the interior orifice of the vent. There are certain general forms in which this enlargement takes place. They may be classed as triangular, lozenge, quadrilateral, star, circular, and elliptic. With the lateral vent of the Dahlgren system it usually takes the lozenge form, the cracks extending from the opposite angles lengthwise of the bore. With those rifled cannon in which the vent is bouched, the cracks appear around the bouching, and although the bouching preserves the vent, yet the formation of fissures around the enlarged orifice, when once commenced, causes a greater tendency to rupture. With the vent not bouched, the wear in rifled cannon is about double that of the smooth-bore. So long as the wear of the vent is regular and without cracks, a mere enlargement is not indicative of danger; but when it reaches a diameter of four tenths of an inch, the vent should be closed and a new one opened. A gun of large caliber should not in service be expected to stand more than 400 or 500 rounds before it will be necessary to open the new vent, which, however, will be of no advantage unless the old one be closed at its interior orifice, on which the gases otherwise would continue to act as a wedge. The first distinct appearance of the cracks, as shown by the button, is the proper limit. After the gun bursts, a sketch or draught is made showing the lines of fracture, and specimens are reserved for trial of density and tensile strength; and, if practicable, a photograph is taken. See *Cannon* and *Ordnance*.

ENEMY.—An enemy, according to the civil law, is one who has publicly declared war against us, or we against him; all others are thieves or robbers. *Hostes hi sunt qui nobis, aut quibus nos, publice bellum decrevimus; cæteri latrones aut prædones sunt.* Thus, in order to constitute an enemy, there must be a public declaration of war. This declaration must also be made by a duly organized State or Kingdom, for a declaration of war by any turbulent body of men is not sufficient; and a hostile act committed by private citizens will not justify a war, unless that act be sanctioned by the Government. The purpose for which this public declaration is required is stated by Grotius to be that it may be clearly known that the war is undertaken not as a venture, but by the will of the two people. Hostilities having been formally declared, every subject of the hostile nations becomes an enemy of the opposing State, as do likewise those independent nations which attach themselves to the interests of either party. According to ancient usage, the utmost violence and cruelty was lawful towards those who were enemies of the State; but by the humane principles which prevail in modern times, warfare is to be carried on subject to certain general rules, which are intended as much as may be to lessen the calamities of war, and to protect the rights of individuals. Thus, an army invading an enemy's country is bound to suffer, as far as possible, the peaceable inhabitants to remain unmolested. Unnecessary devastation of the country and the seizure of property are also contrary to the laws of civilized war; and Grotius lays it down that the use of poisoned weapons, and of assassination, and violence to women, are to be reprobated. On the other hand, individuals taking up arms, without the sanction of the State, in order to annoy an invading enemy, are regarded as lawless marauders. The result of this distinction is that such persons are not treated as prisoners of war, but are subject to be summarily dealt with by the Commander of the Invading Army. It appears to be a recognized principle of international law that the property of an alien enemy residing in either of the hostile States may be confiscated. The Americans, during the war with England, asserted this right in regard to British property found in their territory. But the usage of civilized nations for a long period has much modified the stern rule of law. It is provided by Magna Charta, Cap. 30, that if merchants "be of a land making war with us, and be found in our realm at the beginning of the wars, they shall be attached without any harm of body or goods, until it be known to us, or our Chief-Justice, how our merchants be intreated there in the land making war against us; and if our merchants be well intreated there, theirs shall be likewise with us." Merchants of a Foreign State at war with England were allowed forty days, after proclamation of hostilities, wherein to remove from the Kingdom themselves and their goods; and if that space of time were not sufficient, forty days more were to be conceded to them. Vattel denies that the right to confiscate the goods of an alien enemy is a right inherent in a State by the law of nations, insisting that a Sovereign having permitted foreigners to enter the State, and to continue there, had tacitly promised them full liberty and security for their return. Whatever be the principle, there is no doubt that the almost universal practice of modern nations has been to respect the property of individuals at the outbreak of hostilities. Provisions are frequently inserted into commercial treaties stipulating that, in case of war, the subjects of the enemy shall have time to depart, and even that they should be allowed to remain and carry on a peaceable trade. The right to confiscate the debts of the subjects of a hostile nation appears to rest on the same basis as that of the confiscation of other property. Trade between the subjects of two hostile powers is absolutely suspended during hostilities, unless permitted by express sanction; and the importation of articles particularly useful in war is contraband. All such articles, whether supplied by the subjects of the enemy or of another State, are seized and confiscated. See *Contraband of War*, *Prisoners of War*, and *Prize*.

ENERGY.—When a projectile is in motion it is said to have energy, i.e., it is capable of doing work or overcoming resistance. The amount of energy is measured by the *product of the weight of the projectile into the height due to its velocity*, and is expressed in the same units as those of work done. Thus, if W be the weight of the projectile in pounds, h the height it would acquire in vacuo to attain a velocity v in feet per second, then the energy of the projectile is $Wh = \frac{Wv^2}{2g}$ foot-pounds, where $h = \frac{v^2}{2g}$. If V be the muzzle-velocity of the projectile, its energy at the muzzle of the gun is $\frac{WV^2}{2g}$; and since the energy of the projectile is equivalent to the work done on it, $E = \frac{WV^2}{2g}$, where E represents the energy at the muzzle. It will therefore be seen that the energy of the projectile at the *muzzle* is equal to the work done by the pressure of the powder-gas in the bore of the gun. See *Work*. In order to estimate the comparative power of guns for piercing iron plates, it is usual to express the energy of a projectile in terms of the number of inches in its circumference. Thus, energy per inch of circumference $= \frac{Wv^2}{4480g \times \pi d}$ foot-tons, where d is the diameter of the projectile in inches. Also, energy per inch of circumference at muzzle $= \frac{E}{\pi d} = \frac{WV^2}{4480g \times \pi}$; thus, muzzle-energy per inch of circumference of 10-inch Palliser shell

$$= \frac{5160}{3.1416 \times 9.92} = 165.6 \text{ foot-tons.}$$

In addition to this energy (due to the velocity of translation), there is energy due to the velocity of rotation. This, however, being small as compared to that due to translation, is usually neglected. See *Projectiles*.

ENERGY OF RECOIL.—An expression for the work done in the recoil of a gun when fired. It may be reduced by decreasing the weight of the projectile, by decreasing the muzzle-velocity, or by increasing the weight of the gun and carriage.

ENERGY OF ROTATION.—The power of a rotating body to preserve its axis in the original direction depends upon its *energy of rotation*, or $\frac{W(k\alpha)^2}{2g}$, where W is the weight, k is the radius of gyration, and α is the angular velocity. We thus see that a shell possesses more "energy" than a shot of the same weight rotating at the same speed,—since its radius of gyration is greater.

It will be found that the initial velocity of rotation depends directly on the muzzle-velocity of translation; but the two do not decrease together in flight, the rotation being very slightly decreased even at long range, as has been found by noting scorings on graze.

ENFANS PERDUS.—Forlorn hope; in military history, the soldiers detached from several regiments, or otherwise appointed, to give the first onset in battle, or in an attack upon the counterscarp, or the breach of a place besieged; so called (by the French) because of the imminent danger to which they are exposed.

ENFIELD BREECH-LOADING REVOLVER.—This revolver differs from the patterns usually met with in having a rebounding lock, and in its method of extracting the empty cartridge-cases. The principal parts are the barrel, the cylinder, and the body. The barrel is 5¾ inches in length, and the diameter of bore and the form and twist of the rifling are the same as in the rifle. The barrel is attached to the body by means of a screw passing through a knuckle-joint in an arm which projects below the breech-end. It is held in the firing position by a spring-catch in front of the hammer. The "axis-pin" of the cylinder is screwed into the body, its point resting in a recess in the joint-arm of the barrel. A projection or boss on the cylinder engages in the same recess. By this arrangement, when the catch holding the top bar is released and the barrel depressed, the cylinder is drawn along its axis, and the bases of the cartridges in the chambers being held by a radial extractor, which is free to move only a short distance along the "axis-pin," the cartridge cases are drawn from the chambers to such a distance that those which are empty are free to fall away, while filled cartridges are held by the bullets remaining in the chambers. The cylinder contains six chambers, and the pistol is loaded in the ordinary way. The lock consists of seven components, viz.: hammer, axis-screw, trigger, trigger axis-screw, pawl, lever, and main-spring. The main-spring governs the movement of each component. The act of pulling the trigger cocks the pistol and fires it, and upon the release of the trigger the hammer rebounds to half-cock. The stock is of walnut, and the remaining parts are of steel. The system of manufacture is similar to that of the rifle. Weight of pistol, 2 lbs. 8¼ oz. See *Royal Small-arms.*

ENFIELD RIFLE.—This arm was at one time in use in the British army. It takes its name from the small-arm factory at Enfield, a Government establishment for the manufacture and supply of small-arms of every description to the army. It was originally a muzzle-loading arm, but was subsequently converted into a breech-loader; it is now known as the Snider-Enfield. There are two patterns, that of 1853 having 3 grooves, and that of 1860, 5 grooves. The length of the barrel of the pattern musket of 1853 is 54 inches without the bayonet; having one spiral turn in 78 inches. Weight with bayonet, 9 lbs. 12 oz. The short rifle-musket pattern (1860) is 48¾ inches in length without the bayonet, having one spiral turn in 78 inches. Weight with bayonet, 10 lbs. 4¼ oz. Some of the native regiments in India are armed with the Enfield rifle, and some with the Snider-Enfield.

ENFIELD SIGHT.—With the exception of the Prussian infantry sight, the rear sights of nearly all the modern European small-arms are similar in construction to that of the English Enfield rifle-musket. The only exception seems to be the Swiss sight, which operates on the general principle of the gunner's quadrant. The common features of the Enfield class of rear sights are the long base, which is attached in various ways to the barrel, the leaf with its slides, and the strong flat spring attached to the base to keep the leaf in position, either standing up or lying down.

A peculiar feature of this class of sights is that the elevations corresponding to the shorter ranges are obtained by resting the leaf in certain offsets made in the projecting sides of the base. Great attention has been paid in England toward improving the sight of the Martini-Henry rifle. The sight-notch for short distances is made very open. The slide for long distances has a very faint notch in the middle, and two white lines, one on each side of the central notch, and about a tenth of an inch from it. The object of these lines is to assist the marksman in making allowance for drift and wind. See *Brown Sight.*

The following table gives the length of the stock and position of the rear sight for the principal European guns. These dimensions are considered to have an important effect on the recoil of the gun and the accuracy with which it can be aimed:

Name of Gun.	Distance from center of butt-plate to trigger.	Distance from center of butt-plate to line of rear sight.
	Inches.	*Inches.*
Martini-Henry (British)	14 and 14½	25
Chassepot (French)	13½	21½
Werder (Bavarian)	13½	23½
Mauser (Prussian)	13½	22
Vetterlin (Swiss)	12	21½
Russian (Berdan)	14	21
Werndl (Austrian)	13	22
Comblain (Belgian)	13½	22

ENFILADE.—A military term applied to a fire of musketry or artillery made in the direction of the length of a line of troops or a line of rampart. A besieging battery so placed as to send its shot along any part of the line of a fortification, and inside the parapet, does great execution in dismounting the guns, which thus present the largest surface to the balls. Hence the lines of ramparts should be planned that their prolongations may fall in situations inaccessible to the enemy. Where this is not possible, the lines are either broken, or are protected by bonnets, or by traverses or blindages. In the siege of a fortress the trenches of approach are cut in a zigzag to prevent the defenders enfilading them from the walls.

ENFILADING BATTERY.—Enfilading and counter batteries are used for destroying the artillery and traverses, and silencing the fire of the defenses. Positions are chosen for the enfilading-batteries from which the terre-pleins of the faces, and other lines that bear upon the ground on which the parallels and approaches are laid out, can be swept throughout; the counter batteries are so placed that they can bring a direct or a slant fire against the embrasures of the points to be silenced. The shot from the former is thrown with small charges, under small angles of elevation, so as to ricochet along the terre-pleins, taking the guns of the defenses in flank; the latter fire with full charges directly against the point to be attained. As the effects of both direct and enfilading fire vary greatly with the range, positions should be chosen for these batteries as near the defenses as they can be thrown up without too great a sacrifice of life. Positions which will give ranges between 300 and 700 yards are the best for smooth-bore guns; nearer than 300 yards the workmen would be exposed both to the fire of musketry and case-shot; beyond 700 yards the fire upon the defenses becomes very uncertain.

The greater range of rifled guns gives to the besiegers a greatly enlarged zone in the choice of positions for enfilading and counter batteries over that for the ordinary siege-train of smooth-bore guns. This greater range and the greater certainty of the fire of rifled guns are more favorable to counter-batteries than to those intended for enfilading; as the great angles of elevation under which the guns are fired, to attain the desired ranges, give to the projectile, in the descending branch of its trajectory, a great plunge, which, although more favorable to attaining objects covered by traverses than if the plunge were smaller, is less favorable to the ricochet of the projectile from which the chief advantage of enfilading with round shot is derived. Besides this, the elongated projectiles used in rifled guns from the form given to their point are readily deflected from their course by very slight obstacles, as a fascine even, which also adds to the uncertainty of their effects. At the siege of Fort Wagner it was observed that the heavy projectiles of the smooth-bore navy guns were landed with more accuracy within the enemy's works, and were more destructive in their ricochet, than the projectiles from the army rifled guns.

The judgment and experience of the officer must in these cases be left full play in the selection of the position of the batteries of these two classes of guns and in their armament; bearing always in mind two very important considerations: first, that with long ranges and high angles of elevation the projectiles will clear all the trenches in front up to a near approach of the besieged work without danger to them, except from unforeseen accidents; and second, that to secure any decided or certain effect from either class of these batteries there must be nothing to obstruct the view of the object to be attained. The batteries may be placed either within the parallels, in advance of, or in rear of them. The positions usually selected are from 20 to 30 yards in front of the parallels; because, if placed within them, there might be mutual interference between the service of the batteries and that of the parallels, which is often a very serious cause of delay to both the service of the batteries and the passage of troops; and, unless placed some distance in the rear of it, the parapet of the parallel might obstruct the shot of the battery, and the troops in the trench be annoyed by the fire.

The most effective positions for batteries of smooth-bore guns are in front of the second parallel of from 300 to 400 yards from the point to be reached; and unless the fire of the defenses is very destructive, it will be best to place them there. If placed in front of the first parallel it may be necessary to shift the most of them to the front of the second parallel soon after the latter is thrown up; for the third parallel and the approaches leading to it from the second parallel run the risk of being attained by shot from batteries at so great a distance in their rear as the first parallel. See *Batteries* and *Counter-battery*.

ENGAGE.—A movement in fencing and bayonet-exercise executed as follows: Being in the position of the *guard*, the Instructor commands: 1. *Engage*, 2. TIERCE. At the command *tierce*, numbers one and two cross their bayonets, about 6 inches from the points, the bayonets touching on the right. Engage in *quarte* is similarly executed, the bayonets touching on the left. Each man seeks to cover himself on the side engaged, so as not to be reached by a direct lunge from his adversary.

Being engaged in *tierce*, if number two be too quick to be reached by disengaging, the Instructor commands: ONE, TWO, LUNGE. At the command *one*, number one passes his bayonet quickly under the bayonet of number two, from *tierce* to *quarte;* at the command *two*, he returns quickly from *quarte* to *tierce;* and at the third command, lunges as explained for the *lunge in tierce*. At the command *one*, number two executes *quarte*, *prime*, or *butt parry;* and at the command *two*, executes the *tierce* or *seconde parry*, and then thrusts or lunges at command. If engaged in *quarte*, the feint from *quarte* to *tierce*, the return to *quarte*, and the *lunge* are executed by the same commands, the lunge being in *quarte*. At the command *one*, number two parries in *tierce* or *seconde;* at the command *two*, he executes the *quarte*, *prime*, or *butt parry*, and then thrusts or lunges. Number two is taught the feints in the same manner, and number one executes the double parries. See *Bayonet-exercise*, *Disengage*, and *Fencing*.

ENGAGEMENT.—A military engagement considered as a conflict between two armies or hostile forces cannot be described within limits suitable for this work. Almost every term applicable to armies in the field bears relation, in some way or other, to a hostile engagement, and those terms will be found briefly noticed under their proper headings. A naval engagement admits of more precise and terse illustration than a military engagement, because each ship of war is a unit in itself, bounded by a clearly marked watery margin from all the other ships of a fleet. See *Battle*.

ENGINEER BATTALION.—A component part of the Corps of Engineers, consisting of five companies of Engineers, one Sergeant Major, and one Quartermaster Sergeant, who is also Commissary Sergeant. Each company of Engineer soldiers consists of ten Sergeants, ten Corporals, two Musicians, and as many Privates of the first class, not exceeding sixty-four, and as many Privates of the second class, not exceeding sixty-four, as the President may direct, and is recruited in the same manner, and with the same limitation, and is entitled to the same provisions, allowances, and benefits, in every respect, as are allowed to other troops constituting the present military peace establishment. A Battalion Adjutant, a Battalion Quartermaster, and appropriate officers to command the companies and Battalion of Engineer soldiers, are detailed from the Corps of Engineers. The enlisted men of the Engineer Battalion are instructed in and perform the duties of sappers, miners, and pontoniers, and aid in giving practical instruction in those branches at the Military Academy. They may be detailed by the Chief of Engineers to oversee and aid laborers upon fortifications and other works in charge of the Engineer Corps, and, as fort-keepers, to protect and repair finished fortifications. See *Corps of Engineers*.

ENGINEER COLORS.—In the United States army the national color, as described for the garrison-flag, with the words "U. S. Engineers" embroidered in silver on the center stripe. The battalion color is of scarlet, of the same dimensions as above, bearing in the center a castle, with the letters U. S. above and the word Engineers below, in silver; fringe white. The size of each color, and the length of pike, are the same as described for artillery and infantry colors. Cords and tassels are formed of red and white silk intermixed. See *Colors*.

ENGINEER CORPS.—In modern nations the necessity for a Corps of Staff-officers, trained to arrange for and overcome the embarrassments of the movements of an army in the field, has been thoroughly demonstrated, and hence in most European armies a trained Staff of Officers is organized for this purpose. In the United States a force of about three hundred officers and enlisted men are engaged in these duties. See *Corps of Engineers*, *Engineer Battalion*, and *Royal Corps of Engineers*.

ENGINEERING.—Engineering, the business of the Engineer, is the art of designing and superintending the execution of works of a constructive character, such as roads, railways, bridges, canals, harbors, docks, works for supplying water to towns, drainage and sewerage works, mining machinery, and the working of metals. It may be divided into two kinds—Civil and Military. The Military Engineer is an officer in the service of Government, whose duties are principally to construct fortifications, to make surveys for warlike purposes, to facilitate the passage of an army by the construction of roads and bridges; in short, to execute all engineering works of a military nature; but he is also, especially in this country, called upon to undertake many works which more properly belong to the business of the Civil Engineer, such as the survey of the country, the inspection of public works, and, in short, all the duties of a Government Engineer. The Civil Engineering profession is subdivided into several sections according to the special nature of the employment of its members. The Railway Engineer projects and superintends the execution of railways and all the works in connection with them, such as the alteration of roads and streams, the construction of viaducts, bridges, cuttings, and embankments. The Hydraulic Engineer constructs the works connected with the supply of water to towns, the filtering of water, its collection in reservoirs, and its distribution through a town or district; the irrigation and drainage of tracts of country; the protection of low lands from inundation, and the use of water as a motive power. The Dock and Harbor Engineer has the management of all works connected with the sea or navigable waters, such as the construction of piers, breakwaters, docks, harbors, and light-houses. The Mechanical Engineer is principally concerned in the manufacture of machinery, the working of metals, the construction of ships, steamers, cannon, and all the various structures in which the metals bear a prominent part. Then there is the Mining Engineer, who discovers minerals and manages mines; there are Engineers who are specially engaged in the drainage of towns, and many other less prominent divisions of the profession.

The engineering works of antiquity are both numerous and prominent, many of them remaining while all other traces of their constructors have been swept away. The most notable of the works belonging to very remote antiquity are the harbors of the Phœnicians, the palaces and sewerage of Nimroud, and the pyramids of Egypt; next in order come the harbors of ancient Greece, the bridge of boats across the Dardanelles, made by Xerxes to transport his immense army into Europe, and his canal across the isthmus of the peninsula of Mount Athos. The buildings of ancient Rome next claim attention—its theaters, temples, baths, and its aqueducts, some of which carried water from distances of more than fifty miles into Rome; its roads, bridges, and drainage-works vie in extent and magnificence with the most celebrated works of modern times. From that period down to the commencement of the eighteenth century the most extensive works executed are the canals, embankments, and other hydraulic constructions used by the Dutch for the purposes of inland navigation, and to protect their low lands from the sea; the canals of North Italy, the cathedrals and fortifications of mediæval Europe. Civil Engineering, as a distinct *profession*, may be said to have originated in England about the middle of the last century; since that time the improvements in the steam-engine by James Watt, its subsequent application to the railway system by George Stephenson, and its use in navigation, have given a great impulse to commerce and civilization; which in their turn have created the necessity for the numerous and magnificent engineering works of modern times, such as the innumerable railways, roads, and canals that intersect this and foreign countries; the bridges, water-works, docks, harbors, and vessels that facilitate our commerce and increase our comfort and prosperity. Among the most remarkable of these works may be mentioned the tubular bridges of the St. Lawrence and Menai Strait, the Niagara Railway Suspension Bridge, the New York and Brooklyn Suspension Bridge, and the electric telegraph system, which covers this country and the seas and countries of Europe, and may at some future time connect us with the continents of Australia and India. The education of those who would rise to eminence in the profession must embrace a fair knowledge of pure mathematics and of the mixed sciences of natural philosophy, such as mechanics, hydrostatics, hydraulics, and optics. They should acquire a knowledge of the principles of projections, and should aim at being good draughtsmen and rapid and accurate arithmeticians. In conclusion, it may be said that every day opens fresh fields of Engineering Science and labor; and that as the first beginnings of the art are lost in the obscurity of remote antiquity, so we see no termination to its usefulness and necessity.

ENGINEERS.—The introduction of modern weapons has caused the development of tactics to take a peculiar direction, and has produced changes in the action of the various arms of the service, but nowhere are the changes more marked than in the art of the Engineer.

Looking at the subject generally, we find that one of the first consequences of the development of fire-arms at the end of the sixteenth and beginning of the seventeenth centuries was a large increase of the offensive power of arms, a reduction of defensive armor; and following from this a large increase of field-works. A history of war at this period would be the history of intrenchments, one army seizing a position, intrenching and holding it, the other watching it and afraid to attack.

The increase in roads, the opening up of the country, and the greatly increased size of armies under Napoleon, united to his peculiar strategy, the suddenness of action with which he sought to overcome an enemy, and the great development which the offensive received, all tended to the disuse of field-works and intrenchments. Although the rapidity of Napoleon's marches tended to develop other branches of the Engineer's art, that of bridging and that of the pioneer, to a far greater extent than had previously been known, yet Napoleon was clearly alive to the evils produced by the neglect of field-works. The history of this century shows that field-fortification, when it has been judiciously used, has invariably produced the greatest results, and these results were produced by the application of the same ideas, viz., the use of field-works to cover the front of a large extended position, one considerably larger than the troops could hold in line of battle, the flanks being protected and the communications for supplies being open to the rear. The celebrated lines of Torres Vedras are an instance of this. The English army, with its flanks resting on the Tagus and the sea, occupied with about fifty thousand men a line of some twenty-five miles in length; it had its internal communications perfectly open, its supplies were brought up by the sea, and the French General could do nothing; he was unable to outflank the lines, turn or attack them. They were so strong that any attack in front would have failed; the defenders could not be starved out, and unless they were regularly attacked by siege-works there was no means of dealing with them. From these lines the tide of conquest of the French armies first began to recede. Many years later the same thing happened at Sebastopol. The Russians, holding a long straight line of weak field-works with their communications open, actually advanced from their works, threw up fresh trenches and works, and almost besieged the Allies in their positions. Both these cases were brilliant examples of what field-works properly adapted to tactics can produce. There were great opportunities in the blockades of Paris and Metz for the tactics displayed by the Russians to be repeated; and it is no exaggeration to say that had the garrison of Paris been composed of good troops it might really have dug itself out of Paris and through the German lines.

It appears that at the present day the necessity of making flank attacks has given a fresh importance to field-works. When speaking of this subject previously, the ease with which an army having its flank threatened can change front and attack was pointed out, and it was further pointed out that to prevent such a change of front an attack in front as well as on the flank was needed. Now, is it not possible to check any attempted change of front by the construction of field works? The Americans in the Civil War made a very extensive use of intrenchments for this purpose; they covered their front, and then moved round to a flank. As soon as it was definitely learned with what severe losses front attacks, even when successful, must be uniformly accompanied, and as soon as the true value of temporary field-works on the field of battle was perceived, the further military history of the Civil War is but a narrative of maneuvers whose object was to gain the flanks of the enemy's position, and force him to abandon it by threatening his communications. The system of temporary works on the field of battle was carried to a greater extent during our Civil War than during any war before or since. The troops on each side soon learned to cover themselves at every opportunity, and this was the first duty performed when a halt for any length of time was made by armies in actual contact; in fact, on many occasions breast-works were constructed to cover the army as it advanced. The whole spirit of modern war is to reduce everything to calculation, to leave nothing to chance, to provide for and foresee all possible combinations, whether arising from moral causes, such as panics amongst the men, or from actual physical causes, such as the enemy's fire, or the configuration of the ground; whatever then increases the security of certain places or their defensive power is of the highest importance.

The duties of the Engineers in the field may be divided into two classes: 1. The duties of making, repairing, or destroying communications, including, in the word communication, roads, bridges, railways, and telegraphs. These may be classed together as pioneer duties. 2. The preparation of positions for attack or defense, which is the higher duty of the Military Engineer, and where the art of fortification must be considered entirely in a tactical point of view. With reference to the first class of duties, the men and means must be invariably present when required. The Engineers should march with the advanced-guard, and must be sufficiently supplied with tools and materials. It is the second class of duties, or those of the *Military Engineer* as distinguished from the *Pioneer*, where the tactical relation of field-works to the other arms is fully developed. The mere fact of field-works being constructed is far too often considered as limiting the action of the troops to a strict defensive; viewed in such a light, intrenchments are useless, if not hurtful, and hence arises the absolute necessity of viewing all such works in their tactical relation to troops. In almost every case in war six or seven hours may be calculated on to put a position in a state of defense, and if the Engineers and tools are where they should be, this period is ample: in six hours works of a very powerful nature may be constructed which will effectually support an army. It is generally allowed that an intrenchment occupied by two hundred men offers as much resistance as a battalion not so covered, and that the labor of one thousand men six hours on the position occupied by a division is equivalent to the reinforcement of a brigade. The pioneer duties of the Prussian army were admirably performed, and the true spirit of field-engineering was in many cases seized; one remarkable instance was at Mars-la-Tour. Early in the day the Prussians gained possession of Vionville, on the Verdun Road; the instant the infantry got in, two companies of Engineers supplied with six wagons of tools were pushed on; they were charged by a regiment of French Hussars and lost some of the wagons and a section of one of the companies, but the remainder got into the village, and so strengthened it that all the attempts to retake it failed. And although at the close of the day the Prussian right and left wings were forced back by the French, yet the village of Vionville, forming the apex of the Prussian position, was never lost, and effectually barred the road to Verdun. Here fortification was used correctly; it confirmed and established the success of the infantry, and secured the object for which the Prussians struggled so hard. See *Engineering*.

ENGINEER'S TRANSIT.—A portable instrument of the theodolite kind, designed for measuring both horizontal and vertical angles. The essential parts of the instrument, as shown in Fig. 5, are the *telescope* including its axis and two supports, the *circular plates* with their attachments, the *sockets* upon which the plates revolve, the *leveling-head*, and the *tripod* on which the whole instrument stands.

The *telescope* is from ten to eleven inches long, firmly secured to an axis having its bearings nicely fitted in the standards, and thus enabling the telescope to be moved in either direction, or turned completely around if desired. The different parts of the telescope are shown in Fig. 1. The object-glass, composed of two lenses, so as to show objects without color or distortion, is placed at the end of a slide having two bearings, one at the end of the outer tube, the other in the ring C C suspended within the tube by four screws, only two of which are shown in the cut. The object-glass is carried out or in by a pinion working in a rack attached to the slide, and thus adjusted to objects either near or remote as desired. The eye-piece is made up of four plano-convex lenses, which, beginning at the eye-end, are called respectively the eye, the field, the amplifying, and the object lenses, the whole forming a compound microscope having its focus in the plane of the cross-wire ring B B. Sometimes, especially in English instruments, an eye-piece of two lenses is employed; but this, while it gives more light, inverts the object seen, and so has been discarded by American engineers.

Where it is desired to take greater vertical angles than is possible with the ordinary eye-piece, the little cap on the end of the eye-piece is unscrewed and replaced by one containing a small prism, as shown in Fig. 2, which reflects the image of the object at right angles, and brings it to the eye of an observer from above; when used on the sun, a colored glass or darkener is interposed between the eye and prism. This arrangement consists merely of a diagonal prism attached to the cap of the eye-piece, by which the object is reflected to the eye, placed at right angles to the telescope; when directed to the sun, the little slide or darkener containing colored glass is moved over the opening. The circular plate with which the prism is connected is made to turn in the cap so that when it is substituted for the ordinary cap of the eye-piece, the opening over the prism can be easily adjusted to the position of the eye.

The object-glass receiving the rays of the light which proceed from all the points of a visible object, converges them to a focus at the cross-wires, and there forms a minute, inverted, and very bright image, which may be seen by placing a piece of ground glass to receive it at that point. The eye-piece acting as a compound microscope magnifies this image, restores it to its natural position, and conveys it to the eye. The visual angle which the image there subtends is as many times greater than that which would be formed without the use of the telescope as the number which expresses its magnifying power. Thus, a telescope which magnifies twenty times increases the visual angle just as much, and therefore diminishes the apparent distance of the object twenty times; or in other words, it will show an object two hundred feet distant with the same distinctness as if it were distant only ten feet from the naked eye.

It might be supposed that the greater the power of

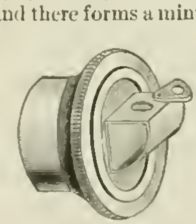

FIG. 2.

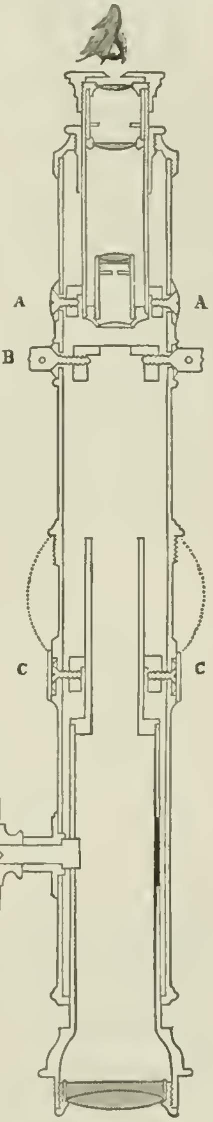

FIG. 1.

a telescope, the better; but in practice, beyond a certain point, this is found to be incorrect. In the first place, as only a given amount of light can enter the object-glass, the more the object is magnified the less clear and bright will it appear; and again, the higher the power the more difficult will it be to precisely focus the telescope and to complete its adjustment. We have found that a power of from twenty to twenty-four diameters in the telescopes of transits gives the best results and is amply sufficient for all ordinary practice.

The Kellner eye piece, the main feature of which is the use of a compound amplifying-lens, as shown in Fig. 1, in place of the single one heretofore employed, has sensibly increased the brilliancy of the object and secured a better field. This is now applied to all transit-telescopes. The eye-piece is brought to its proper focus usually by twisting its milled end, the spiral movement within carrying the eye-tube out or in as desired; sometimes a pinion, like that which focuses the object-glass, is employed for the same purpose.

The cross-wires, shown in Fig. 3, are two fibers of spider-web or very fine platinum wire, cemented into the cuts on the surface of a metal ring, at right angles to each other, so as to divide the open space in the center into quadrants. To remove the cross-wire ring, take out the eye-piece tube, together with the little ring by which it is centered, and having removed two opposite cross-wire screws, with the others turn the ring until one of the screw-holes is brought into view from the open end of the telescope-tube; in this thrust a pointed splinter of wood or a small wire, so as to hold the ring when the remaining screws are withdrawn; the ring is then taken out. It may be replaced by returning it to its position in the tube, and either pair of screws being inserted, the splinter or wire is removed, and the ring is turned until the other screws can be replaced. Care must also be taken that the same side of the ring is turned to the eye-piece as before it was removed. When this has been done, the eye-tube is inserted, and its centering ring brought into such a position that the screws in it can be replaced, and then by screwing on the end of the telescope the little cover into which the eye-tube is fixed the operation will be completed.

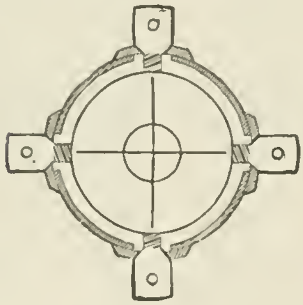

Fig. 3.

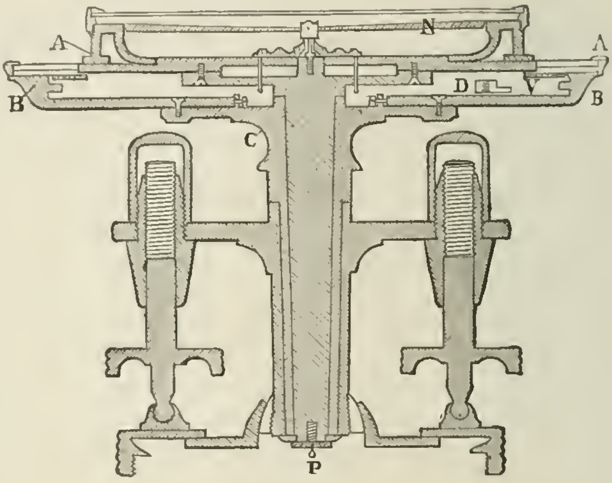

Fig. 4.

The advantage of platinum for the cross-wires of telescopes has long been conceded, but the difficulty of procuring it of sufficient fineness has prevented its general adoption. Platinum wires are now drawn of a fineness of from one eight-thousandth to one twelve-thousandth of an inch, and are used in the telescopes of all the best instruments, unless spider-lines are specially desired. These wires are perfectly opaque, and of course entirely unaffected by moisture, and are universally preferred to the spider-web heretofore used.

The intersection of the wires forms a very minute point, which, when they are adjusted, determines the optical axis of the telescope, and enables the surveyor to fix it upon an object with the greatest precision. The imaginary line passing through the optical axis of the telescope is termed the "line of collimation," and the operation of bringing the intersection of the wires into the optical axis is called the "adjustment of the line of collimation." This will be described further on. The openings in the telescope-tube are made considerably larger than the screws, so that, when these are loosened, the whole ring can be turned around for a short distance in either direction. The object of this will be seen more plainly when we describe the means by which the wire is made truly vertical. The sectional view of the telescope, Fig. 1, also shows two movable rings, one placed at A A, the other at C C, which are respectively used to effect the centering of the eye-piece and the adjustment of the object-glass slide. The centering of the eye-tube is performed after the wires have been adjusted, and is effected by moving the ring, by means of the screws shown on the outside of the tube, until the intersection of the wires is brought into the center of the field of view.

The adjustment of the object-slide, which will be hereafter described, secures the movement of the object-glass in a straight line, and thus keeps the line of collimation in adjustment through the whole range of the slide, preventing at the same time what is termed the "traveling" of the wires. This adjustment is always made in the process of construction, and, needing no further attention at the hands of the engineer, is concealed within the ring near the ball of the telescope-axis.

In Fig. 5 the telescope is represented as plain, or without any attachments, such as vertical circle, level, etc.; but many if not most engineers prefer to have two or more of these accessories, and it will be well to briefly describe the same in this connection.

The standards of the transit are firmly attached by their expanded bases to the upper plate, one of them having near the top, as shown in the drawing, a little movable box, actuated by a screw underneath, by which the telescope-axis is made truly horizontal, as will be hereafter described

The circular plates, with their accompanying sockets, are shown in section in Fig. 4; the upper plate, A A, carrying the compass-circle, etc., is screwed fast to the flange of the interior spindle; the lower plate or divided limb, B B, is fastened to the exterior socket C, which again is fitted to and turns in the hollow socket of the leveling-head. The compass-box, containing the needle, etc., is covered by a glass to exclude the moisture and air; the circle is silvered, and is divided on its upper surface or rim into degrees and half-degrees, the degree-marks being also cut down on its inner edge, and figured from 0 to 90 on each side of the center or line of zero.

The magnetic needle is four to five inches long in the different sizes of transits, its brass cap having inserted in it a little socket or center of hardened steel, perfectly polished, and this, resting upon the hardened and polished point of the center-pin, allows the needle to play freely in a horizontal direction and thus take its direction in the magnetic meridian. The needle has its north end designated by a scallop or other mark, and on its south end a small coil of fine brass wire, easily moved, so as to bring both ends of the needle to the same level. The needle is lifted from the pin by a concealed spring underneath the upper

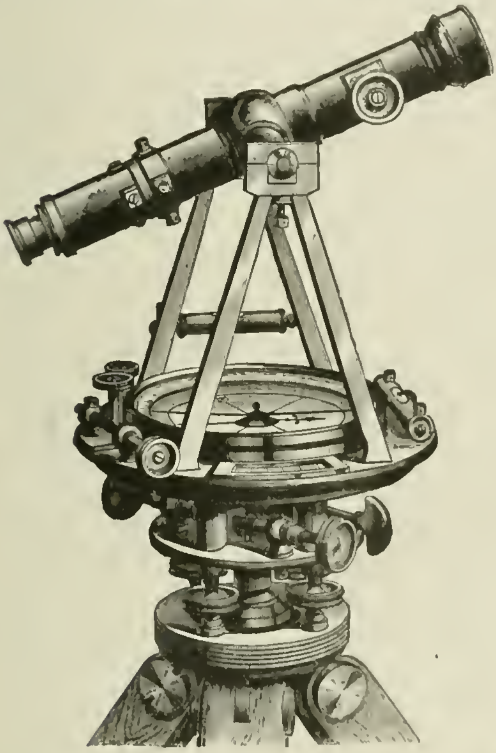

Fig. 5.

plate, actuated by a screw shown above, thus raising the button so as to check the vibrations of the needle, or bring it up against the glass when not in use, to avoid the unnecessary wear of the pivot. The forms of the needle are almost infinitely varied, according to the taste or fancy of the maker or surveyor, but may be resolved into two general classes, one having the greatest breadth in a horizontal, the other in a vertical, direction. The test of the delicacy of a magnetic needle is the number of horizontal vibrations which it will make in a certain arc before coming to rest; besides this most surveyors prefer also to see a sort of quivering motion in a vertical direction. This quality, which is manifested more in a horizontal than in a vertical needle, and depends upon the near coincidence of the point of suspension with the center of gravity of the needle, serves to show merely that the cap below is unobstructed.

The clamp and tangent movement, shown in Fig. 5, on the upper plate, serves to fasten the two plates together, so that by the tangent screw they can be slowly moved around each other in either direction, or loosened at will and moved by the hand, thus enabling one to direct the telescope rapidly and accurately to the point of sight. The opening for the clamp in the upper plate is covered by a plate or a washer, as shown, to exclude the dust and moisture. The clamping-piece into which the clamp-screw enters is shown at D, Fig. 4.

The two levels are shown placed at right angles to each other so as to level the plate in all directions, and adjusted by turning the capstan-head screws at their ends by a small steel adjusting-pin. The glass vials used in the levels of this transit are ground on their upper interior surface, so as to make the bubble move evenly and with great sensitiveness.

The lower plate or limb, BB, Fig. 4, is divided on its upper surface—usually into degrees and half-degrees—and figured in two rows, viz., from 0 to 360, and from 0 to 90 each way; sometimes but a single series is used, and then the figures run from 0 to 360, or from 0 to 180 on each side. The figuring is varied according to the wish of the engineer, the double series being always used unless otherwise desired. The two verniers, V V, are attached to the upper plate diametrically opposite to each other, and serve to read the limb around which they revolve.

The verniers are double, having on each side of the zero-mark thirty equal divisions corresponding precisely with twenty-nine half-degrees of the limb; they thus read to single minutes, and the number passed over is counted in the same direction in which the vernier is moved. The use of two opposite verniers in this and other instruments gives the means of "cross-questioning" the graduations, the perfection with which they are centered, and the dependence which can be placed upon the accuracy of the angles indicated. Sometimes a finer reading than minutes is desired, and then the divisions of the limb and vernier are both made smaller, so as to give readings to 30, 20, or even 10 seconds of arc, if required. The vernier-openings are covered with glass, carefully cemented to exclude the moisture and dust. Reflectors of silver or celluloid, as in the mountain-transit, are often used to throw more light upon the divisions, and, more rarely, shades of ground glass are employed to give a clear but more subdued light.

The graduations are made commonly on the brass surface of the limb, afterwards filled with black wax, and then finished and silvered. Many instruments, however, have a solid silver plate put over the brass and the graduations made on the silver itself. The last is more costly, but insures a finer graduation, with less liability to tarnish or change color.

The sockets of the transit, as shown in Fig. 4, are compound; the interior spindle attached to the vernier-plate turning in the exterior socket, C, when an angle is taken on the limb, but when the plates are clamped together the exterior socket itself, and with it the whole instrument, revolves in the socket of the leveling-head. The sockets are made with the greatest care, the surfaces being truly concentric with each other, and the bell-metal or composition of which they are composed of different degrees of hardness, so as to cause them to move upon each other easily and with the least possible wear.

The leveling-head, also shown in Fig. 4, consists of two plates connected together by a socket having at its end a hemispherical nut fitting into a corresponding cavity in the lower plate. The plates are inclined to each other or made parallel at will by four leveling-screws, of which only two are shown in the section. The screws are of bronze or hard composition metal and fitted to long nuts of brass, screwed into the upper parallel plate; and, as will be noticed, have threads only on the upper ends, the lower part of their stems turning closely in the lower unthreaded part of the nuts. By this arrangement dust is excluded from the lower end of the screws, while the brass cover above equally protects the other end. The screws rest in little cups or sockets, which are secured to their ends and in which they turn without marring the surface of the lower plate, the cups also permitting the screws to be shifted from side to side, or turned around in either direction on the lower plate.

The clamp and tangent movement of the leveling-head, partially shown in Fig. 5, serves to turn the whole instrument upon its sockets, so as to fix the telescope with precision upon any given point, and when unclamped allowing it to be directed approximately by hand. The tangent-screws, as will be seen, press on opposite sides of the clamp-piece, and thus insure a very fine and solid movement of the instrument.

The lower leveling-plate is made in two pieces—the upper one, which is screwed fast to the top of the tripod, having a large opening in its center, in which the smaller lower one is shifted from side to side or turned completely around. By this simple arrangement, termed a "shifting center," the instrument is easily moved over the upper plate, and the plummet which hangs from the center, P, Fig. 4, set precisely over a point, without moving the tripod.

The tripod, the top of which is shown in Fig. 5, has three mahogany legs, the upper ends of which are pressed firmly on each side of a strong tenon on the solid bronze head by a bolt and nut on opposite sides of the leg; the nut can also be screwed up at will by a wrench furnished for the purpose, and thus kept firm. The lower end of the leg has a brass shoe with an iron point, securely fastened and riveted to the wood.

Every instrument should leave the hands of the maker in complete adjustment; but all are so liable to derangement by accident or careless use that we deem it necessary to describe particularly those which are most likely to need attention. The principal adjustments of the transit are: 1. The levels; 2. The line of collimation; 3. The standards.

To adjust the levels, set up the instrument upon its tripod as nearly level as may be, and having unclamped the plates, bring the two levels above and on a line with the two pairs of leveling-screws; then with the thumb and first finger of each hand clasp the heads of two, opposite; and, turning both thumbs in or out, as may be needed, bring the bubble of the level directly over the screws, exactly to the center of the opening. Without moving the instrument proceed in the same manner to bring the other bubble to its center; after doing this, the level first corrected may be thrown a little out; bring it in again; and when both are in place, turn the instrument half-way around; if the bubbles both come to the center, they would need no correction, but if not, with the adjusting-pin turn the small screws at the end of the levels until the bubbles are moved over half the error; then bring the bubbles again into the center by the leveling-screws, and repeat the operation until the bubbles will remain in the center during a complete revolution of the instrument, and the adjustment will be complete. It should be remarked that in this as in most transits the level on the standards has a movement only at one end, the adjustment being made by abutting screws, which are loosened and tightened in turn, in moving the level.

To adjust the line of collimation,—i.e., to bring the intersection of the wires into the optical axis of the telescope, so that the instrument when placed in the middle of a straight line will, by the revolution of the telescope, cut its extremities—proceed as follows: Set the instrument firmly on the ground and level it carefully; and then having brought the wires into the focus of the eye-piece, adjust the object-glass on some well-defined point, as the edge of a chimney or other object, at a distance of from two hundred to five hundred feet; determine if the vertical wire is plumb, by clamping the instrument firmly and applying the wire to the vertical edge of a building, or observing if it will move parallel to a point taken a little to one side; should any deviation be manifested, loosen the cross-wire screws, and, by the pressure of the hand on the head outside the tube, move the ring around until the error is corrected. The wires being thus made respectively horizontal and vertical, fix their point of intersection on the object selected; clamp the instrument to the spindle, and having revolved the telescope, find or place some good object in the opposite direction, and at about the same distance from the instrument as the first object assumed. Great care should always be taken, in turning the telescope, that the position of the instrument upon the spindle is not in the slightest degree disturbed. Now, having found or placed an object which the vertical wire bisects, unclamp the instrument, turn it half-way around, and direct the telescope to the first object selected; having bisected this with the wires, again clamp the instrument, revolve the telescope, and note if the vertical wire bisects the second object observed. Should this happen, it will indicate that the wires are in adjustment, and the points bisected are, with that of the center of the instrument, in the same straight line. If not, however, the space which separates the wires from the second point observed will be double the deviation of that point from a true straight line, which may be conceived as drawn through the first point and the center of the instrument, since the error is the result of two observations, made with the wires when they are out of the optical axis of the telescope.

In order that the wires may trace a vertical line as the telescope is moved up or down, it is necessary that both the standards of the telescope should be of precisely the same height. To ascertain this and make the correction when needed, proceed as follows: Having the line of collimation previously adjusted, set up the instrument in a position where points of observation, such as the point and base of a lofty spire, can be selected, giving a long range in a vertical direction. Level the instrument, fix the wires on the top of the object and clamp to the spindle; then bring the telescope down until the wires bisect some good point, either found or marked at the base; turn the instrument half around, fix the wires on the lower point, clamp to the spindle, and raise the telescope to the highest object. If the wires bisect it, the vertical adjustment is effected; if they are thrown to either side, this would prove that the standard opposite that side was the highest, the apparent error being double that actually due to this cause. To correct it, one of the bearings of the axis is made movable, so that by turning a screw underneath this sliding piece, as well as the screws which hold on the cap of the standard, the adjustment is made with the utmost precision. This arrangement, which is common to all the best telescope-instruments, is very substantial and easily managed.

Besides the three adjustments already described—which are all that the surveyor will ordinarily have to make—there are those of the needle and the object-glass slide, which may sometimes be required. The first is given with the description of the compass. To adjust the object-glass slide: Having set up and leveled the instrument, the line of collimation being also adjusted for objects from three hundred to five hundred feet distant, clamp the plates securely, and fix the vertical cross-wire upon an object as distant as may be distinctly seen; then, without disturbing the instrument, throw out the object-glass, so as to bring the vertical wire upon an object as near as the range of the telescope will allow. Having this clearly in mind, unclamp the limb, turn the instrument half-way around, reverse the eye-end of the telescope, clamp the limb, and with the tangent-screw bring the vertical wire again upon the near object; then draw in the object-glass slide until the distant object first sighted upon is brought into distinct vision. If the vertical wire strikes the same line as at first, the slide is correct for both near and remote objects; and, being itself straight, for all distances. But if there be an error, proceed as follows: First, with the thumb and forefinger, twist off the thin brass tube that covers the screws, CC, shown in Fig. 1. Next, with the screwdriver, turn the two screws, CC, on the opposite *sides* of the telescope, loosening one and tightening the other, so as apparently to increase the error, making, by estimation, one half of the correction required.

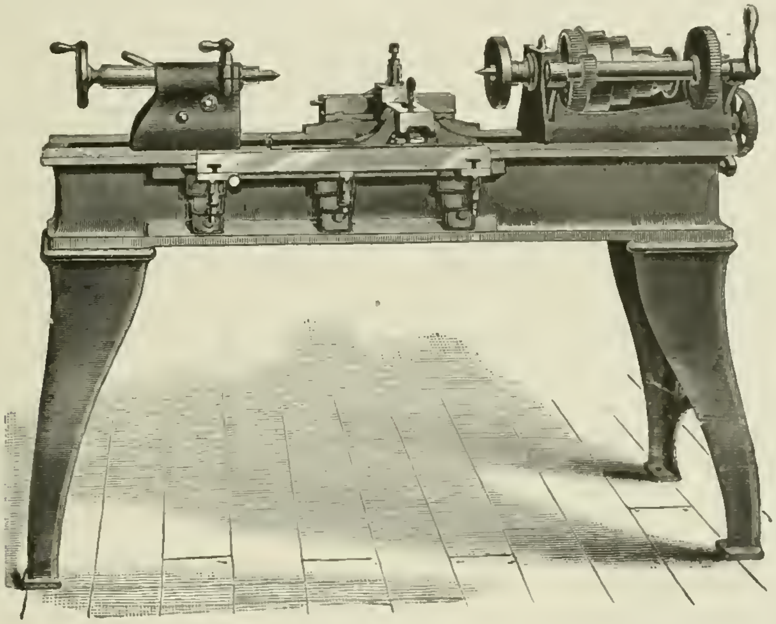
Then go over the usual adjustment of the line of collimation, and having it completed, repeat the operation above described; first sighting upon the distant object, then finding a near one in line, and then reversing, making correction, etc., until the adjustment is complete. This adjustment is peculiar to the transits made by Messrs. W. and L. E. Gurley, of Troy, N. Y., and furnishes the only way in which the line of collimation can be made correct for all distances.

When using the transit, care should be taken to have it set up firmly, the tripod-legs being pressed into the ground, so as to bring the plates as nearly level as convenient; the plates should then be carefully leveled and properly clamped, the zeros of the verniers and limb brought into line by the upper tangent-screw, and the telescope directed to the object by the tangent-screws of leveling-head. The angles taken are then read off upon the limb, without subtracting from those given by the verniers, in any other position. Before an observation is made with the telescope, the eye-piece should be moved in or out, until the wires appear distinct to the eye of the operator; the object-glass is then adjusted by turning the pinion-head until the object is seen clear and well defined, and the wires appear as if fastened to its surface. The intersection of the wires. being the means by which the optical axis of the telescope is defined, should be brought precisely upon the center of the object to which the instrument is directed. The needle is used, as in the compass, to give the bearings of lines, and as a rough check upon the angles obtained by the verniers and limb; but its employment is only subsidiary to the general purposes of the transit. The instrument as described is manufactured by the Messrs. Gurley, United States. See *Mountain-transit, Prismatic Transit, Sextant, Solar Attachment, Solar Compass, Theodolite, Transit-instrument*, and *Y-level.*

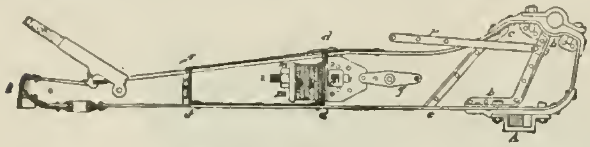
ENGINE-LATHE.—A lathe of the larger kind, having a capacity for all the principal turning work of the armory. That shown in the drawing is a 13-inch weighted engine-lathe, with screw and back gears. It swings 13 inches over the bed and 6 inches over the carriage. The front bearing of the head-stock spindle is $1\frac{3}{4}$ inch diameter and $3\frac{3}{4}$ inches long, in cast-iron boxes lined with Babbitt-metal. Screw-thread on spindle for face-plate $1\frac{3}{4}$ inch diameter, 8 pitch. The cone, largest diameter 9 inches, is driven by a belt 2 inches wide. The hole through the spindle is $\frac{9}{16}$ inch diameter. The small feed-gears are of wrought-iron. With the usual set of gears, screws may be cut with threads of 4 to 64 to the inch. Stationary and follow rests, countershaft, and wrenches accompany the lathe. Speed by countershaft, 9 by 3 inch friction-pulleys, 140 revolutions per minute. Lathe with 4-foot bed receives 1 foot 8 inches between centers, and weighs 1100 pounds. Beds 4 to 6 feet long.

A larger size of the same pattern swings 16 inches over the bed and 8 inches over the carriage. The front bearing of the live-spindle is $4\frac{1}{2}$ inches long by $2\frac{1}{4}$ inches diameter. The cone, largest diameter $12\frac{3}{4}$ inches, is driven by a belt $2\frac{1}{2}$ inches wide. The hole through the spindle is $\frac{9}{16}$ inch diameter; screw-thread on spindle for face-plate, $2\frac{1}{4}$ inches diameter, 6 pitch. With the usual set of gears, screws of from 3 to 48 threads to the inch may be cut. Speed of countershaft, 10 by 3 inch friction-pulleys, 120 revolutions per minute. This size of lathe is made, also, with gibbed carriage and cross-feed. It swings $10\frac{1}{2}$ inches over the carriage. Lathe with 5-foot bed receives 2 feet between centers, and weighs 1475 pounds. Beds 5 to 8 feet long. See *Lathe.*



Engine-lathe.

ENGLEHARDT GUN-CARRIAGE.—The great strain brought on the carriage by firing the large charges that are used in the new artillery renders the construction of the carriage a difficult problem, to be sure of the required strength without exceeding the limits of the weight hitherto deemed admissible, which cannot be exceeded without encountering grave objections in the service of the piece. Already many attempts have been made to lessen the shock on the carriage by the introduction of springs of different forms, intended to give a certain elasticity and avoid breakage. A carriage of this kind was exhibited at Vienna by the Bochum Company. The desired elasticity was obtained by the use of a Brown's spiral spring, arranged somewhat in the same manner as in Colonel Englehardt's carriage. Metallic springs are, at best, frail, subject to accidents, and otherwise objectionable; consequently this carriage does not seem to have found favor. Colonel Englehardt, of the artillery of the Imperial Guard, has experimented in Russia on a carriage of this kind, which, it appears from the experiments made, has given highly satisfactory results. The carriage is distinguished by its simplicity of construction, and is composed essentially of two parts, the carriage proper, and the slide and wheels. The carriage is formed of two cheeks of sheet-iron, the edges formed up and joined together by a lunette and four transoms, two of which, *bb*, *cc*, are between the cheeks, and two, *dd*, *ff*, are in the trail; these last also form the ends of the trail-chest, in which the elastic cushion is placed. The different details of the construction are given in the figure, in which the elevating-apparatus is not shown; only the stays, *p*, and the journals for its trunnions are represented. It will be sufficient to point out in the drawing the iron plate *t*, a kind of spade, riveted and bolted to the end of the trail, intended to penetrate the ground when the carriage is in battery, and to check the recoil. The part which the inventor designates by the term slide embraces the axle, A, with the wheels; it is joined by two rods, not shown in the drawing, to a strong cross-head, *g*. The axle-understraps, as well as the hole in



Englehardt Gun-carriage.

the trail for the cross-head, are sufficiently long to allow the pieces which work in them considerable play, so that the slide may move without imparting motion to the carriage. Under all other circumstances except violent shocks, produced by firing or by similar causes, the carriage and slide are united in an unalterable manner by means of an elastic cushion. This is composed of five strong sheets of cork, *h*, pressed between the transom *d* and a movable plate, *m*. The two strong bolts *i* pass through the whole and are secured to the cross-head, *g*. By turning the nuts on the ends of the bolts *i* any desirable initial compression may be brought on the sheets of cork. When the gun is discharged, the carriage, on account of the inertia of the slide, begins to slip, the resistance to which at the first moment brings into play the elasticity of the cork cushion. The inventor hopes that as the carriage proper alone receives the shock of the discharge, the whole system will suffer less fatigue. See *Field-carriages.*

ENGLISH FRICTION-PRIMER.—The tube is a quill; but as the material has not sufficient strength or firmness to resist the force of the pull necessary to withdraw the friction-wire, a loop of leather is attached to the quill which passes over a knob or projection cast on the gun just forward of the vent. The quill is destroyed by the combustion of the charge, and all accidents from the flying of the tube are obviated. The leather loop, however, is perishable and does not last for any great length of time. See *Friction-primer.*

ENGLISH FUSE.—The common name for the *Moorsom fuse.* It is very complicated in its construction, but a great importance is attached to it in England. See *Moorsom Fuse.*

ENGLISH SYSTEM OF RIFLING.—A modification of the French system, consisting of deep and broad grooves, each of which receives two soft-metal circular studs attached to the projectile. The grooves are three or more in number, according to the caliber of the piece; they are 1.05 inch wide, and .18 of an inch deep, with curved edges, both the loading and driving edges being struck with the same radius. The bottom of the grooves is eccentric to the bore, being struck with a radius of three inches; they are of the same width for all natures of heavy guns, but are a little deeper for the 10-inch gun and upwards; the grooves are also widened at the muzzle in the larger guns, in order to facilitate loading by cutting away the loading-side slightly for two inches from the muzzle. This system embraces uniform and increasing twists, the latter being preferred. Both the direction and twist are given by the bearing of the studs on the grooves, the body of the projectile never being intended to come into contact with the bore. The windage is .8 of an inch in all calibers. The projectiles have two studs for each groove in all instances; both studs in the case of the uniform twist, and the rear one where the twist is increasing, are nearly of the size of the groove, with their faces corresponding to the curved bottom of the groove. In the large projectiles an intermediate row has been introduced, making three rows in all, and a soft-metal gas-check has been applied to the base of the projectile. The rear stud is four inches from the bottom of the projectile, and the studs of each groove are equidistant from the center of gravity. The particulars of rifling are as follows: The 12-inch gun, 9 grooves; twist increasing from 1 in 100 to 1 in 50 calibers at muzzle. The 10 inch gun, 7 grooves; twist increasing from 1 in 100 to 1 in 40 calibers at muzzle. The 9-inch gun, 6 grooves; twist increasing from 0 to 1 in 45 calibers at muzzle. The 8-inch gun, 4 grooves; twist increasing from 0 to 1 in 40 calibers at muzzle. The 7-inch gun, 3 grooves; twist uniform, 1 in 35 calibers. The 7-inch gun has a uniform twist because, at the time of its introduction, the uniform was preferred to the increasing spiral. See *System of Rifling* and *Woolwich Gun.*

ENGRAILED.—In Heraldry, the line composed of a series of little half-moons, or semicircles, supposed to have been made in it by hail. Engrailed is the opposite of *inverted.* See *Heraldry.*

ENGUICHE.—A hunting-horn, the rim around the mouth of which is of a different color from the horn itself, is said heraldically to be *enguiché*, of the color in question. See *Heraldry.*

EN L'AIR.—Literally, in the air, unsupported. It is said that a division is *en l'air* when it is unsupported or too far from the army either to render assistance or to receive support. For instance, at the beginning of the war of 1870–71 General Douai was at Bellfort, MacMahon in the east of the Vosges, De Failly, *en l'air,* between Frossard and the Duke of Magenta.

ENLARGEMENT.—The act of going or being allowed to go beyond the prescribed limits; as the extending the boundaries of an arrest, when the officer is said to be enlarged, or under arrest at large. Enlargements of the bore and vent are injuries suffered by all cannon that are subjected to rapid and constant firing and erosion. When it becomes considerable, the vent is rebouched.

ENLISTMENT.—The mode by which the English army is supplied with troops, as distinguished from the conscription prevailing in many other countries. Enlistment was in private hands until the year 1802, middlemen procuring recruits, and receiving a profit or commission for their trouble. This system being subject to much abuse, the matter was taken into the hands of the Government in the above-named year, and is now managed by the Adjutant General. Formerly a soldier enlisted for life, and could never look forward to a period of freedom; or, at best, he could not retire on a pension while still possessed of a fair share of health and strength. This system was changed in 1847 by an Act relating to *limited* enlistment; which provided that a man should enlist for 10 years for the infantry, or for 12 for the cavalry or artillery. At the expiration of this period he could either quit the army, without pension; or re-enlist for the remainder of 21 years for the infantry, or 24 years for cavalry or artillery. This second period of service entitled the soldier to a pension for life, after his discharge: and in 1868 twopence a day was added to the pay of every soldier who re-enlisted (or re-engaged). This system of enlistment provided soldiers; but did nothing for the growth of trained reserves, with which to bring the army to fighting strength in the event of war. The "Army Enlistment Act" of 1870 seeks to remedy this defect, by allowing men to enlist for 12 years, with the understanding that 6 years or less shall be passed with the Colors, and the remainder with the Reserve. This is known as "short service." If apprentices enlist, the master may recover them under certain conditions detailed in the Mutiny Act (which is passed every year). The Mutiny Act also provides that servants enlisting before the term of their engagement are validly enlisted, and are entitled to wages up to the date of enlistment. Periods of imprisonment are not reckoned as part of the time of limited enlistment. A recruit enlists into either one of the 70 sub-district brigades, each of which comprises either a two-battalion regiment or two single-battalion regiments, or he enlists for general service in any regiment to which the Adjutant General may post him; but artificers, as armorers, etc., are usually enlisted for general service, so that their services may be made available where most required. The Army Discipline and Regulation Act of 1879 made several important alterations in regard to enlistment. The recruit had always to appear before a Magistrate, but formerly could not refuse to take the oath without paying a fine of 20*s*. Now he is not enlisted until he appear before the Magistrate, who causes to be read to him a series of authorized questions, and satisfies himself that the man is not under the influence of liquor, and voluntarily agrees to enlist. The recruit then signs the declaration, takes the oath, and is attested by the Magistrate. If the recruit does not so appear, or appearing does not assent, no further proceedings are taken. If within three months of his attestation a recruit pays a sum not exceeding £10, he is now entitled to be discharged.

Enlistment in the United States army is superintended by the Bureau of the Recruiting Service, the Chief Officer of which is stationed in New York City. There are quarters or branches in nearly all the large cities of the Union, and two Depots to which recruits are sent—Fort Columbus, New York Harbor, and the Barracks at Newport, Ky. Men are enlisted for five years, and may be assigned to any branch of the service.

The following is a list of the various "calls" for troops by the United States Government during the War of the Rebellion:

Date of Call.	Number of Men.	Term of Service.	Number obtained.
April 15, 1862	75,000	3 months	93,326
May to June 25, 1862	530,000	3 years	714,213
July 2, 1862	300,000	3 years	431,958
August 4, 1862	300,000	9 months	87,000
October 17, 1863	300,000	3 years }	374,807
February 1, 1864	200,000	3 years }	
March 14, 1864	200,000	3 years	284,021
July 18, 1864	500,000	1-2-3 years	384,882
December 19, 1861	300,000	1-2-3 years	204,568

There were other calls for 30 and 100 days' men. The whole number called for was 2,759,049; total obtained, 2,656,553. By Act of Congress March 3, 1863, called the "Conscription Act," the President was authorized to draft troops. The Act provided for an enrollment, a draft, the reception of substitutes, and arrest of deserters. About 3,000,000 men between the ages of 20 and 45 were enrolled. The calls from October 17, 1863, were orders for drafts. But probably not more than 50,000 drafted men performed personal service. Substitutes were obtained. The "Substitute Fund" of the Government, consisting of money paid in as a release from service, and which was used as a "bounty fund" for volunteers, amounted to $25,902,029.

ENNISKILLEN DRAGOONS.—A British regiment of horse: it was first instituted from the brave defenders of Enniskillen, in 1689.

ENROLL.—To place a man's name on the roll or nominal list of a body of soldiers. See *Enlistment*.

ENSCONCE.—A term generally signifying, in a military sense, to cover as with a fort.

ENSEIGNE.—The Colors. The French designate all warlike symbols under the term *enseigne;* but they again distinguish that word by the appellations of *Drapeaux*, Colors, and *Etendards*, Standards. *Drapeaux* or Colors are particularly characteristic of the infantry; *Etendards* or Standards belong to the cavalry.

ENSEMBLE.—Together: the exact execution of the same movements performed in the same manner and by the same motions. It is the union of all the men who compose a battalion, or several battalions or companies of infantry and cavalry, who are to act as if put in motion by the same spring. See *Cadence*.

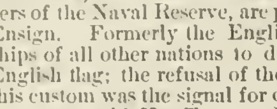
ENSIGN.—1. Until 1871 Ensign was the title of the lowest combatant rank of Commissioned Officers in the British army, and is derived from their being charged with the duty of carrying the Regimental Colors or Ensign. In the hand-to-hand mêlées of the Middle Ages, the preservation of the Colors or Standard, as the rallying-point of those fighting under the same leader, was a matter of vital importance, and was only intrusted to the bravest and most trustworthy. The Colors were committed to him with imposing ceremony in presence of the assembled regiment, and he had to take an oath to defend them with life and limb, and if need were, to wrap himself in them as a shroud, and devote himself to death. The man who undertook this perilous post received sometimes as much as sixfold the usual pay. It was doubtless in this way that the point of honor arose respecting the Colors. History records repeated instances where the oath was kept to the letter. In the modern system of warfare the Regimental Colors are seldom exposed to such danger, and the office of Ensign is of less account. In the infantry there were two kinds of Subalterns below the Captain, viz., the Lieutenant and the Ensign. In the cavalry and the artillery the duties of Ensign were taken by officers who had the titles of Cornet or Second Lieutenant. When a gentleman entered the army he began as an Ensign (if in the infantry), and from this rank he rose by purchase or seniority. The pay was 5*s*. 3*d*. per day, and the half-pay 1*s*. 10*d*. to 3*s*.; although it was most unusual for an Ensign to be on half-pay. An Ensign in the Foot-guards ranked as a Lieutenant in the army, and, on transferring his services to an infantry or cavalry regiment, exchanged with an officer of that grade.

The rank of Ensign having been abolished in the British army, the number of Lieutenants has been proportionately increased; but for three years the officer only receives the same pay as the Ensign formerly had. The officer enters in the probationary grade of Sub-lieutenant, which is converted to Lieutenant as soon as he proves himself qualified to command soldiers and perform the other duties of the office. In the late East India Company's army, a Cadet became an Ensign in rank and pay directly he landed in India.

2. In the United States navy an Ensign is the National Flag. It is also used in the merchant-service to designate the country to which the vessel belongs. There is an officer in the navy called Ensign who ranks below Master and above Midshipman. In the army and the militia an Ensign is assigned to each company, his duty being to carry the flag or standard of the company. Sometimes the duty falls to a Sergeant.

Ensign is also the name of one of the flags belonging to the British fleet; and, under that or some other name, to most other fleets. It is a large flag or banner hoisted on an Ensign staff, a long pole erected over the poop, or at the gaff when the ship is under sail. Its chief purpose is to denote the nation to which the ship belongs. The English Ensign has for a groundwork one of three colors—red, white, or blue—and bears the union double cross of St. George and St. Andrew, or Union Jack, in the upper corner next the mast (dexter-chief). The *white* Ensign is also divided into four quarters by a red cross of St. George, and is limited to ships-of-war. Merchant-vessels are only allowed to carry the *blue* Ensign; but yachts, if of clubs acknowledged by the Admiralty, colonial armed vessels, ships connected with Government Departments, and merchant-vessels commanded by officers of the Naval Reserve, are permitted to use the *red* Ensign. Formerly the English Admirals required ships of all other nations to dip their Ensigns to the English flag; the refusal of the Dutch to comply with this custom was the signal for one of Blake's bloodiest encounters with Van Tromp. See *Flags* and *Standard*.

ENTANGLEMENTS.— Every approach which an enemy might use to reach a work should be so obstructed as to keep him as long as possible under a close fire of musketry. The best thing for this purpose is wire entanglement, made by planting stout stakes, about $3\frac{1}{2}$ feet long, 2 feet in the ground and 7 feet apart, in quincunx order and in three or four lines, as shown in the drawing. Around the tops of these stakes, at from 12 to 18 inches from the ground, in notches prepared for the purpose, telegraph or other strong wire is very securely wound, extending from one stake to another. This obstacle is rapidly made, is difficult to remove, and can be injured but little by the fire of the enemy. A kind of abatis formed of trees, with the trunks cut half through, forms a very serious obstacle to the advance of an assailant.



ENTERPRISER.—An officer who undertakes or engages in any important and hazardous design.

ENTIRE.—A line of men in one continued row by the side of each other. When formed behind each other they are said to be in file. The usual expression is *rank entire*.

ENTONNOIR.—The cavity or hole which remains after the explosion of a mine. It likewise means the tin-case or port-fire which is used to convey the priming-powder into the vent of a cannon. See *Crater*.

ENTRENCH.—To construct hastily thrown-up field-works for the purpose of strengthening any force in position. When the ground is undulating, rocky, or woody, it is easy to avoid the enemy's sight and fire; but when it is bare and level, the art of entrenching is of first importance. The history of all battles of late years has shown the expediency of making use of natural shelter or constructing field-intrenchments. Not only is such artificial shelter necessary in action, but it is frequently invaluable for the purpose of concealing the troops before the fire has opened. A very slight parapet of newly excavated earth is sufficient to protect men from the effects of rifle-balls. Experiment shows that the penetration of the ball (service-rifle) at a range of 10 yards is 20 inches, and only 10 inches at 200 yards. After a little practice, each soldier will ascertain the form of pit that best suits and protects him. The depth need not be uniform, but should be at least 10 inches where the body rests, and 6 inches elsewhere. With a view to lessening the effect of the enemy's fire, the soldier should lie down well under and behind the cover. The soldier should never be separated from an intrenching-tool of some description. Many are the instances recorded where it was impossible to forward the intrenching-tools to the front until after the exigency for their use had passed, and the men were compelled to use tin plates, tin cans, fragments of canteens, knives, sticks, etc., in order to get temporary shelter from the enemy's most galling fire. See *Intrenchment*.

ENTREPOT.—An intermediate depot for the reception of stores and arms in a garrison town where there is no arsenal or magazine.

ENVELOPE.—The name applied to the continuous enceinte formed when the counter-guards of the bastions are joined to those of the ravelins.

ENVIRON.—In a military sense, to inclose or surround in a hostile manner; to hem in; to besiege.

EPARCH.—The Governor of a Province in ancient Greece, or Prefect of a region under the rule of Rome. In modern Greece a Province of the Kingdom is called a Monarchy, and a subdivision of a Monarchy an Eparchy. In Russia the term denotes the Diocese or Archdiocese of a Bishop or Archbishop.

EPAULE.—In fortification, the shoulder of a bastion, or the place where its face and flank meet and form the angle, called the angle of the shoulder.

EPAULEMENT.—In fortification, a portion of a battery or earthwork. The siege-batteries are generally shielded, at one end at least, by epaulements, forming an obtuse angle with the main line of the battery. The object is to protect the guns and gunners from a flanking fire. The name is often given erroneously to the parapet of the battery itself, but it applies properly to the flanking return only. Sometimes the whole of a small or secondary earthwork, including the battery and its flanks, is called an epaulement; and sometimes the name is given to an isolated breastwork intended to shield the cavalry employed in defending a body of besiegers. An epaule is the shoulder of a bastion, where one of the faces and one of the flanks meet: and this points to the proper meaning of epaulement, as a shoulder or flanking work. The following distinctions are usually observed: When the covering mass is so constructed as to afford the assailed a view and fire over the assailant's line of approach, it is termed a *parapet;* when intended simply as a screen or cover from the fire of the enemy, it is termed an *epaulement;* and when used to cover troops or guns from an enfilading fire on the flank or in the rear, it is known as a *traverse*. See *Parapet* and *Traverse*.

EPAULETS—EPAULETTES.—Shoulder-knots worn by military and naval officers, as the marks of distinction, and as ornaments. In the British navy the officers of and above the rank of Lieutenant wear epaulets of gold lace, one on each shoulder, Sub-lieutenants wearing one only. The ranks and degrees are marked in a very systematic way by means of crowns, anchors, and stars worked in silver on the epaulet, and also by the size of the cords of the epaulets itself. This decoration was formerly universal in the British army, officers wearing those of gold, men of worsted; but they were abolished during the Russian war, in consequence of the dangers to which officers thus easily marked out were exposed. It is retained by the French army alone of the armies of the great Powers. Epaulets are worn by General Officers in the United States service, as also by the officers of most militia organizations. The following patterns are prescribed for General Officers:—*For the General of the Army:* Of gold, with solid crescent; device—two silver embroidered stars, with five rays each, $1\frac{1}{2}$ inch in diameter, and the "Arms of the United States" embroidered in gold placed between them. *For a Lieutenant General:* Of gold, with solid crescent; device—three silver embroidered stars of five rays each, respectively $1\frac{1}{2}$, $1\frac{1}{4}$, and $1\frac{1}{8}$ inch in diameter. The largest placed in the center of the crescent; the others placed longitudinally on the strap and equidistant, ranging in order of size from the crescent. *For a Major General:* Same as for Lieutenant General, omitting smallest star, and the smaller of the two remaining stars placed in the center of the strap. *For a Brigadier General:* Same as for Lieutenant General, omitting everything but the largest star. See *Shoulder-knots*.

EPAULIERE.—A thick strap of leather employed in ancient times. It passed over the shoulder and sustained the cuirass, composed of two pieces, breast- and back-plate. See *Cuirass*.

EPEE DE PASSOT.—A very short sword of Italian origin, used in the fifteenth century, and very much like the *anelace*.

EPHEBI.—In Grecian antiquity, the name given to the Attic youth from the age of eighteen till they entered upon their twentieth year. During this period they served a sort of apprenticeship in arms, and were frequently sent, under the name of *peripoli*, to some of the frontier towns of Attica to keep watch against foreign invasion.

EPIBATÆ.—In Grecian antiquity, the name given to soldiers whose duty it was to fight on board ship. They corresponded almost exactly to the Marines of modern naval warfare. The term is sometimes found in Roman authors to denote the same class of soldiers, but the general phrase adopted by them is *milites classiarii*, or *socii navales*.

EPIGNARE.—A small variety of ordnance which does not exceed one pound in caliber.

EPIGONI.—A term which signifies the "heirs" or "descendants." It was applied to the Sons of the Seven Chiefs who conducted an expedition against Thebes to restore Polynices, and who were all killed except Adrastus. Ten years later, the Epigoni—namely, Alcmæon, Thersander, Diomedes, Ægialeus, Promachus, Sthenelus, and Euryalus—renewed the enterprise and took Thebes. The War of the Epigoni was celebrated by several ancient epic and dramatic poets.

EPINGLETTE.—A large iron needle with which the cartridge of any large piece of ordnance is pierced before it is primed.

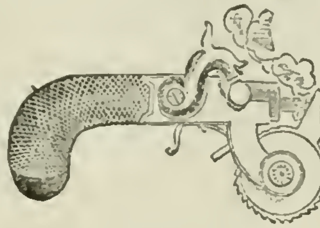
EPINIKIAN.—Pertaining to or celebrating victory; as, an epinikian ode.

EPITAGMA.—All the elementary tactical combinations, or *formations*, of the Greeks were methodical, but yet very simple. An army corps was composed of a *tetraphalangarchia*, also termed a grand phalanx, consisting of 16,354 oplitai. An *epitagma*, of 8192 psiloi; and an epitagma of cavalry of 4096 men. The heavy-armed or infantry of the line bore to the light infantry and cavalry the ratio of the numbers 2, 4, and 1. The epitagma of cavalry was divided into two equal parts, each composed alike, termed *telea*. One was placed on each wing of the line of battle. The telos was subdivided into 5 divisions; the strength of each subdivision being the half of the one next in order above it. The lowest, termed *ila*, of 64 horsemen, corresponding to the modern squadron, was drawn up on a front of 16 with 4 files, and was commanded by an officer to whom was given the title of *Ilarch*.

E PLURIBUS UNUM.—"One out of many." A motto adopted by the United States since the "Declaration of Independence," in 1776.

EPOUVANTE.—A sudden panic with which troops are seized, and under which they retreat without any actual necessity for so doing.

EPROUVETTE.—A machine for proving or testing the strength of gunpowder. It was invented or suggested in the last century by Robins, but was greatly improved by Dr. Hutton. The gun-eprouvette determines the strength of gunpowder by the amount of recoil produced. A small gun, usually a "half-pounder," is fixed to the lower end of an iron rod, its base being adjusted to an arm projecting from the rod; or else it is suspended from an iron frame. A horizontal steel axis is fixed to the rod or frame about which the gun may vibrate. A pointed iron rod or style projects downwards from the lower side of the gun, and touches a groove filled with soft wax; the groove is so shaped that, when the gun recoils, the point cuts a path for itself along this wax; and the length of this path determines the amount of recoil. Sometimes a brass graduated arc with an index is used instead of the pointed style and the waxed groove; but the principle of action is just the same. On the arc the recoil should vary from 26° for new fine-grain powder to 20° 5′ for old powder of coarse grain. This system of proof is resorted to annually at minor and foreign stations for the proof of all powder in store, to ascertain the amount of deterioration; five rounds constitute the minimum proof. Before the eprouvette is resorted to, the powder must pass the test of specific gravity, by weighing not less than 55 lbs. to the cubic foot. The mortar-eprouvette determines the strength of gunpowder by the distance to which a ball is projected, instead of the distance to which the piece recoils. It is generally a mortar of



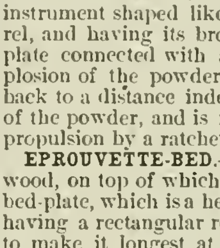
Eprouvette.

8-inch bore, in which 2 to 4 ounces of powder is employed to propel an accurately turned iron shot to a distance of about 120 yards. Other things being equal, the strongest gunpowder sends the shot to the greatest distance; and this is the usual mode adopted in testing gunpowder supplied to the Government by various contractors. The ordinary eprouvette is an instrument shaped like a small pistol without a barrel, and having its breech-chamber closed by a flat plate connected with a strong spring. On the explosion of the powder against the plate, it is driven back to a distance indexed according to the strength of the powder, and is retained at its extreme state of propulsion by a ratchet-wheel.

EPROUVETTE-BED.—This consists of a block of wood, on top of which is countersunk and bolted the bed-plate, which is a heavy circular plate of cast-iron, having a rectangular recess, with sloping sides, so as to make it longest at the bottom. Into this recess the sole of the mortar slides. The wooden block is bolted to a stone block of the same size, which is firmly placed in the ground on a masonry foundation. The bed is 22 inches long by 22 inches wide, and weighs 280 pounds. See *Platform*.

EQUALIZE.—To render the distribution of any number of men equal as to the component parts. To *equalize a battalion* is to tell off a certain number of companies, usually eight, in such a manner that the several component parts shall consist of the same number of men.

EQUATION OF DEFENSE.—Let A B C D represent the line of an interior crest; A B C D, that of the foot of the banquette slope; F, the outlet through the parapet; and E, the interior traverse. Representing



by x the number of yards in the side A B, the side A B will be equal to x diminished by twice the distance between A B and A B, which distance may be taken on an average at nine yards; the area of the square B C, or of the terre-plein, will then be represented by $(x-9)^2$. Let the following notation be adopted: y, the number of the garrison; r, the reserve taken from the garrison; n, the number of ranks on the banquette for the defense; s, the area of the terre-plein occupied by a barbette in the salient; s', the area occupied on the terre-plein by the powder-magazine; s'', the area occupied by the traverse, and the passage in its rear; l, the number of yards on the interior crest for a barbette in the salient; l', the width of the outlet F in yards. Now, as the area allowed for each man is one and a half square yards, we shall obtain the following equation, to represent the relation between the terre-plein, the garrison, etc.:

$$(x-9)^2 = 1.50\,y + s + s' + s'' \quad . \quad . \quad . \quad (1)$$

This is termed *the equation of the interior space*. As each man occupies one lineal yard along the interior crest, we obtain also

$$4x = \frac{y - r}{n} + l + l'; \quad . \quad . \quad . \quad . \quad . \quad (2)$$

which is termed *the equation of defense*, as it expresses the relation between the development of the interior crest, the remainder of the garrison after taking out the reserve, the number of ranks for the defense, and the length of the interior crest required for the cannon in barbette, and for the outlet. To show the application of the equations (1) and (2), let it be required to find the side of a redoubt, and the number of its garrison, which shall be defended by two ranks on the banquette, after taking out a reserve of one third of the whole number, and have a barbette in each salient. By a calculation, easily made, it can be shown that each barbette will occupy about seventy-five square yards of the terre-plein; a powder-magazine for four guns, twenty square yards; a traverse of earth, with the passage between it and the foot of the banquette, about 180 yards; or, if of timber, about fifty square yards; the portion of the interior crest for each barbette will be nearly eighteen lineal yards, and that for the passage about four lineal yards. Taking equation (2), and making the substitutions required by the conditions of the problem, we obtain

$$4x = \frac{y - \frac{1}{3}y}{2} + 4 + 72;$$

and from it, $y = 12x - 228.$

Substituting this value of y in equation (1), and placing for s, s', s'', their values, we have

$$(x - 9)^2 = 18x - 342 + 300 + 20 + 180,$$

or $$(x - 9)^2 = 18x + 158;$$

from which, by solving the equation,

$x = 38$ yards;
consequently $y = 228$ men,
and $r = 76$ men.

EQUATION OF TIME.—It is well known that the earth's motion in the ecliptic—or what is the same thing, the sun's apparent motion in longitude—is not uniform. This want of uniformity would of itself obviously cause an irregularity in the time of the sun's coming to the meridian on successive days; but besides this want of uniformity in the sun's apparent motion in the ecliptic, there is another cause of inequality in the time of its coming on the meridian, viz., the obliquity of the ecliptic to the equinoctial. Even if the sun moved in the equinoctial, there would be an inequality in this respect, owing to its want of uniform motion; and even if it moved uniformly in the ecliptic, there would be such an inequality, owing to the obliquity of its orbit to the equinoctial. These two independent causes conjointly produce the inequality in the time of its appearance on the meridian, the correction for which is the Equation of Time.

When the sun's center comes to the meridian, it is apparent noon; and if it moved uniformly on the equinoctial, this would always coincide with *mean noon*, or 12 o'clock on a good solar clock. But from the causes above explained, mean and apparent noon differ, the latter taking place sometimes as much as 16½ minutes before the former, and at others as much as 14½ minutes after. The difference for any day, called, as we have said, the Equation of Time, is to be found inserted in ephemerides for every day of the year. It is nothing or zero at four different times in the year, at which the whole mean and unequal motions exactly agree; viz., about the 15th of April, the 15th of June, the 31st of August, and the 24th of December. At all other times the sun is either too fast or too slow for clock-time. In the ephemerides above referred to, the sign + or − is prefixed to the equation of time, according as it is to be added to or subtracted from the apparent time to give the mean time. See *Time*.

EQUATIONS OF MOTION OF PROJECTILES.—In the article TRAJECTORY, the following relation between the co-ordinates of a point of the trajectory, the angle of projection, and the height due to the velocity is found to exist, viz.,

$$y = x \cdot \tan A - \frac{x^2}{4h \cdot \cos^2 A}. \quad . \quad . \quad . \quad (1)$$

V being the initial velocity, it is readily seen that

$$y = Vt \sin A - \tfrac{1}{2}gt^2; \quad . \quad . \quad . \quad . \quad (2)$$

also, $$x = Vt \cos A, \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

and $$t = \frac{x}{V \cos A}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

To determine the vertical ascent and horizontal range of the projectile, differentiate equation (1), and place the value of $\frac{dy}{dx} = 0$; whence we obtain

$$X = 4h \sin A \cos A = 2h \sin 2A \quad . \quad . \quad (5)$$

$\frac{1}{2}X$ being the abscissa of the highest point,

$$Y = h \sin^2 A. \quad . \quad . \quad . \quad . \quad . \quad (6)$$

The first value of X shows that the range can be obtained with two angles of projection, provided they be complements of each other; the second value shows that the greatest range corresponds to an angle of 45°, and that this range is equal to twice the height due to the velocity; and also that variations in the angle of fire produce less variations in range as the angle of fire approaches 45°.

If two projectiles be thrown under the same angle, with different initial velocities, V and V', the ranges being X and X', we have

$$X = 2h \sin 2A = \frac{V^2}{g} \sin 2A, \quad \text{and} \quad X' = \frac{V'^2}{g} \sin 2A;$$

and from these we have

$$\frac{V}{V'} = \frac{\sqrt{X}}{\sqrt{X'}}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

Therefore, under the same angle of fire, the ranges are proportional to the squares of the velocities; and reciprocally, the velocities are proportional to the square roots of the ranges.

The velocity at any stated point is equal to $\frac{ds}{dt}$, or $v^2 = \frac{dy^2 + dx^2}{dt^2}$. Substituting the values of dy and dx obtained by differentiating equations (2) and (3), we have $v^2 = V^2 - 2Vgt \sin A + g^2t^2$. Substituting for $-2Vgt \sin A + g^2t^2$ its value $-2gy$ derived from equation (2), we have $v^2 = V^2 - 2gy$. Replace V^2 by $2gh$, and reducing, the expression becomes

$$v = \sqrt{2g(h - y)}, \quad . \quad . \quad . \quad . \quad (8)$$

This shows that the velocity of a projectile at any point depends on its height above the muzzle of the piece, and that it is equal to that which is attained in falling through the height $(h - y)$. It also shows that the velocity is least when y is greatest, or at the summit of the trajectory; and that the velocities at the two points in which the trajectory cuts the horizontal plane are equal.

The total time of flight may be determined by substituting the value of $X = 4h \sin A \cos A$, equation (5), in equation (4), which becomes

$$T = \frac{4h \sin A}{V} = \frac{V \sin A}{\frac{1}{2}g}. \quad . \quad . \quad . \quad . \quad (9)$$

If $A = 45°$, $\sin A = \sqrt{\tfrac{1}{2}}$, and $V = \sqrt{gX}$. Calling $T_{,}$ the time of flight, we have

$$T_{,} = \sqrt{\frac{X}{\frac{1}{2}g}} = \sqrt{\frac{X}{16.07}} = \tfrac{1}{4}\sqrt{X}.$$

Hence the time of flight for an angle of 45° is equal to the square root of the quotient of the range divided by one half of the force of gravity; or, it is approximately equal to one fourth of the square root of the range expressed in feet.

The tangent of the angle made by a tangent line at any point of the trajectory is equal to $\frac{dy}{dx}$, which is obtained by differentiating equation (1); calling this angle θ, we have

$$\tan\theta = \tan A - \frac{x}{2h\cos^2 A}. \quad . \quad . \quad . \quad (10)$$

Substitute the value of $X = 4h \sin A \cos A$, the angle of fall on horizontal ground is $\tan\theta = -\tan A$; that is to say, the angle of fall is equal to the angle of projection, measured in an opposite direction.

The position of a point being given, to find the initial velocity necessary to attain it. Let a and b be the horizontal and vertical co-ordinates of this point of the curve, and ε its angle of elevation. Substituting these quantities in equation (1), and recollecting that $\tan\varepsilon = \frac{b}{a}$, we have

$$h = \frac{a\cos\varepsilon}{4\sin(A-\varepsilon).\cos A},$$

or

$$V = \sqrt{\frac{ag\cos\varepsilon}{2\sin(A-\varepsilon).\cos A}}. \quad . \quad . \quad . \quad (11)$$

The position of a point being given, to find the angle of fire necessary to attain it. Substituting a and b for x and y in equation (1) we have

$$b = a\tan A - \frac{a^2}{4h\cos^2 A}$$

from which to determine A. Making $\tan A = \alpha$, we have $\cos^2 A = \frac{1}{1+\alpha^2}$; which being substituted in the above equation gives

$$\alpha = \tan A = \frac{1}{a}\left(2h \pm \sqrt{4h^2 - 4hb - a^2}\right). \quad (12)$$

The two values of tan A show that the point may be attained by two angles of projection; and the radical shows the solution of the problem is possible when the quantity under it is positive; or, $4h^2 > 4hb + a^2$.

The preceding formulæ will only be found to answer in practice for projectiles which experience slight resistance from the air, or for heavy projectiles moving with low velocities, as is commonly the case with those of mortars and howitzers. The following table gives the difference between the observed and calculated times of flight of the French 8- and 10-inch mortar-shells, weighing 64 and 119 pounds respectively. The initial velocities being unknown, the times are calculated from the observed ranges. The observed times are invariably greater than the calculated times, as might be expected from the resistance of the air, which retards the motion of projectiles.

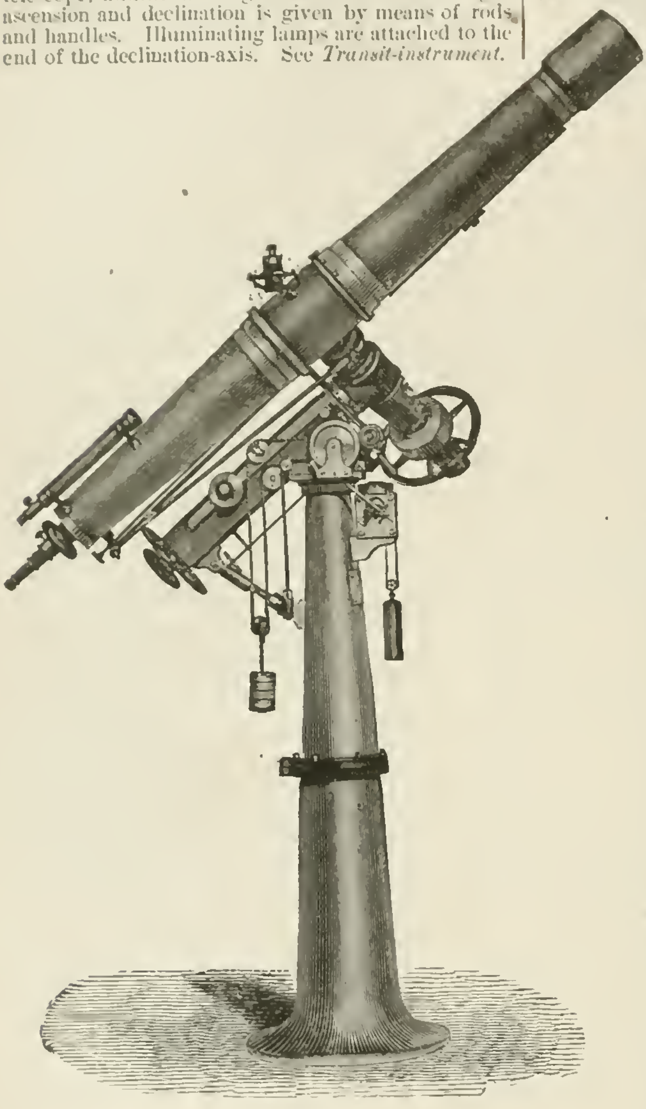
Kind of projectiles.	Weight of powder.	Ranges at angles of		Times of flight.			
				45°		30°	
		45°	30°	Observed	Calculated.	Observed	Calculated.
	Kilog.	Met'rs	Met'rs	Sec.	Sec.	Sec.	Sec.
8-inch..	0.234	343	290	9.8	8.4	6.8	5.8
	0.351	629	561	12.9	11.3	10.0	8.1
	0.585	1146	1011	16.0	15.3	12.3	10.9
	0.994	1792	1690	20.8	19.2	16.9	14.1
10-inch.	0.468	457	383	11.0	9.7	7.5	6.8
	0.693	734	637	14 0	12.2	10.0	8.7
	1.054	1132	980	17.0	15.2	12.0	10.2
	1.405	1555	1355	20.0	17.8	14 0	12.6
	1.639	1757	1516	23.0	18 9	15.0	13.4

The next table shows the observed and calculated ranges for 30° elevation, and the observed ranges for 45° elevation, for the above projectiles, the initial velocities being the same for each projectile.

Ranges of 10-in. Mortar-shells.				Ranges of 8-in. Mortar-shells.			
45° elevation.	30° elevation.			45° elevation.	30° elevation.		
Observed.	Observed	Calculated.	Difference.	Observed.	Observed	Calculated.	Difference.
Meters.	Met'rs	Met'rs	Met'rs	Meters.	Met'rs	Met'rs	Met'rs
457	383	396	+13	343	290	298	+ 8
734	637	637	0	629	561	545	−16
1132	980	982	+ 2	1146	1011	993	−18
1555	1355	1350	− 5	1792	1690	1552	−138
1757	1516	1522	+ 6				

It appears from the foregoing tables that the ranges of mortars with different degrees of elevation can be calculated up to about 1400 yards from equation (5), or $X = 2h \sin 2A$; and the times from equation (4); or $T = \frac{X}{V\cos A}$. See *Didion's Formulas*, *Resistance of the Air*, and *Trajectory*.

EQUATORIAL.—An important astronomical instrument, by which a celestial body may be observed at any point of its diurnal course. It consists of a telescope attached to a graduated circle, called the declination-circle, whose axis penetrates at right angles that of another graduated circle called the hour-circle, and is wholly supported by it. The pierced axis, which is called the principal axis of the instrument, turns on fixed supports; it is pointed to the pole of the heavens, and the hour-circle is of course parallel to the equinoctial. In this position it is easy to see that a great circle of the heavens, corresponding to the declination-circle, passes through the pole, and is an hour-circle of the heavens. The telescope is capable of being moved in the plane of the declination-circle. If, now, the instrument be so adjusted that the index of the declination-circle must point to zero when an equatorial star is in the center of the field of view of the telescope, and the index of the hour-circle must point to zero when the telescope is in the meridian of the place, it is clear that when the telescope is directed to any star, the index of the declination-circle will mark the declination of the star, and that on the other circle its right ascension. If the telescope be clamped when directed on a star, it is clear that, should the instrument be made to rotate on its principal axis with entire uniformity with the diurnal motion of the heavens, the star would always appear in the field of view. This motion of rotation is communicated to the instrument by clockwork. The drawing shows the instrument as made by Fauth and Company, United States. The telescope can be moved in right ascension without stopping the clock or disengaging the worm. When moved sufficiently the clock acts again with the regular rate, without previous clamping. If desired, an additional right-ascension circle is provided, driven by an auxiliary clockwork, which is kept running. An index shows the right ascension of the point to which the telescope is then directed. The rate of the driving-clock is readily changed from sidereal to lunar. The instrument is provided with a number of micrometrical and astronomical eye-pieces; transit eye-pieces and sun-shades; improved position micrometer, with parallactic eye-piece movement, fine movement for spider-line, and rapid movement for entire micrometer to traverse the field. The micrometer-head is divided on silver; the whole revolutions are read off on a separate dial, which, in our opinion, is the prettiest device for recording whole turns. The position-circle is divided on silver, reading by opposing verniers and microscopes to minutes or hundredths of a degree. Large declination and hour circles are divided on silver and read with two verniers and microscopes to five seconds of arc and single seconds of time respectively. A coarse graduation, with pointer, for convenience in setting, is put on the edge. The driving-clock with a conical pendulum is connected with the polar axis and can be thrown in and out of gear from the eye-end of the telescope; additional tangent-screw motion in right ascension and declination is given by means of rods and handles. Illuminating lamps are attached to the end of the declination-axis. See *Transit-instrument.*



Equatorial.

EQUERRY.—At the British Court, a subordinate officer under the Master of the Horse, who is usually a military man. There is a Chief Equerry, also four Equerries in ordinary, and an Equerry of the Crown Stables. Each member of the royal family has one or more Equerries.

EQUESTRIAN.—A man who rides on horseback. *Eques auratus* is a term in Heraldry for a knight.

EQUESTRIAN ORDER.—This body originally formed the cavalry of the Roman army, and is said to have been instituted by Romulus, who selected from the three principal Roman tribes 300 Equites. This number was afterward gradually increased to 3600, who were partly of patrician and partly of plebeian rank, and required to possess a certain amount of property. Each of these Equites received a horse from the State; but about 403 B.C. a new body of Equites began to make their appearance, who were obliged to furnish a horse at their own expense. These were probably wealthy *novi homines*, men of equestrian fortune, but not descended from the old Equites (for it should be observed that the equestrian dignity was hereditary). Until 123 B.C. the Equites were exclusively a military body; but in that year Caius Gracchus carried a measure by which all the *Judices* had to be selected from them. Then, for the first time, they became a distinct order or class in the State, and were called *Ordo Equestris.* In 70 B.C. Sulla deprived them of this privilege; but their power did not then decrease, as the forming of the public revenues appears to have fallen into their hands. After the conspiracy of Catiline, the Equestrian Order, which on that memorable occasion had vigorously supported the Consul Cicero, began to be looked upon as a third estate in the Republic; and to the title of *Senatus populusque Romanus* was added *et equestris ordo.* But, even in the beginning of the Empire, the honor, like many others, was so indiscriminately and profusely conferred that it fell into contempt, and the body gradually became extinct. As early as the later wars of the Republic, the Equites had ceased to constitute the common soldiers of the Roman cavalry, and figured only as officers.

EQUESTRIAN STATUE.—The representation of a man on horseback. Equestrian statues were awarded as a high honor to Military Commanders and persons of distinction in Rome, and latterly were, for the most part, restricted to the Emperors, the most famous in existence being that of the Emperor Marcus Aurelius, which now stands in the Piazza of the Capitol at Rome. It is the only ancient equestrian statue in bronze that has been preserved; an exemption which it probably owed to the fact that for centuries it was supposed to be a statue of Constantine. The action of the horse is so fine, and the air of motion so successfully given to it, that Michael Angelo is said to have called out to it "Cammina!" (Go on, then!). It was originally gilt, and traces of the gilding are still visible on the horse's head. So highly is this statue prized, not only for its artistic but its historical value, that an officer used regularly to be appointed by the Roman Government to take care of it, under the designation of the Custode del Cavallo. On the occasion of the rejoicings by which Rienzi's elevation to the Tribuneship was celebrated in 1347, wine was made to run out of one nostril and water out of the other of this famous horse. The statue then stood in front of the Church of St. John Lateran, near to which it was found, and a bunch of flowers has always been presented annually to the chapter of that basilica, in acknowledgment of ownership, since it was removed to its present site on the Capitol. All European capitals are adorned, or disfigured, by numerous equestrian statues, London belonging preeminently to the latter category.

EQUIP.—To furnish an individual, a corps, or an army with everything that is requisite for military service, such as arms, accouterments, uniforms, etc.

EQUIPAGE.—In military matters, the name given to certain of the necessaries for officers and soldiers. During the Crimean War many officers applied for and obtained money as compensation for the loss or injury of their equipage, comprising horses, horse-appointments, baggage, saddlery, and accouterments. Equipments issued to private soldiers are expected to last a certain number of years, and small deductions from their pay are made in the event of the articles

Equipment and Accoutrements. Flags, standards, sabrès, muskets, pikes, bayonets, helmets, caps, shakos, plumes, cuirasses, knapsacks, cartridge-belts, haversacks, sapping and mining tools, etc., of various European countries. *Russian:* **1**—1, 4, 12, 27; **2**—1; **3**—1, 2, 7, 10; **4**—2, 3, 9; **5**—3, 15, 16. *Austrian:* **1**—5, 9, 15, 21, 22, 27, 33, 37, 39, 43, 44; **2**—4, 9, 10, 12, 22; **3**—6, 11, 13; **5**—6. *Prussian:* **1**—6, 13, 14, 19, 29, 32, 34, 35, 38, 45, 46; **2**—6, 11, 13, 14, 16, 17, 18, 19, 20; **3**—4, 5, 9, 12, 14; **4**—7, 8, 10; **5**—12, 18, 20. *Saxony:* **1**—2, 3, 7, 18, 20, 36; **5**—4, 8. *French:* **1**—10, 26, 28, 40; **2**—8; **3**—13; **4**—12. *Wurtemberg:* **1**—11, 16. *Bavarian.* **1**—17; **4**—1, 11. *Danish:* **1**—23; **2**—7; **4**—6; **5**—7. *Braunschweig:* **1**—25, 31, 42; **2**—2, 5; **5**—5. *Hanover:* **2**—21. *Swedish:* **3**—3, 8. *English:* **4**—5; **5**—13. *Portugese:* **5**—1. *Spanish:* **5**—2.

V—496.

not lasting the proper time. In those cases (in the English army) where a non-commissioned officer receives a commission on the ground of meritorious service, an allowance of £100, if in the infantry, or £150, if in the cavalry, is made to him to provide an equipment. The equipage of a private soldier is often used as a name for the whole of his clothes, arms, and accouterments collectively. The *equipage* of an army is of two kinds: it includes all the furniture of the camp, such as tents and utensils, under the name of *camp-equipage;* while *field-equipage* comprises the saddle-horses, baggage-horses, and baggage-wagons.

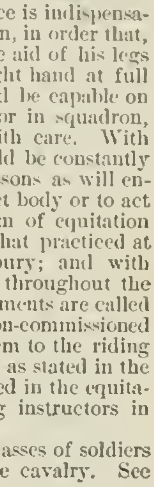
EQUIPMENT-FUND.—A fund for the benefit of Cadets graduating at the United States Military Academy. Four dollars per month is deposited with the Treasurer from the pay of each Cadet, to be applied, at the time of his promotion, to the purchase of a uniform and equipments. See *Cadet.*

EQUIPMENTS.—A general term signifying the arms and accouterments and all such articles as are worn or carried by the soldier; they are supplied by certain Departments charged with their administration. In the artillery service the term *equipment* includes the ordnance and carriages, the supply of ammunition and stores. In the cavalry, all articles of saddlery, and such as the horse carries, are included under this head. *Cannoneers' equipments* include the *hausse-pouch, cartridge-pouches, primer-pouches,* and *thumb-stall,* used in the field-service. The equipments for a field-piece are the *tampion* and *strap, vent-cover,* and *tarpaulin.* Other things used in the service of cannon are called implements. In the mounted service *horse-equipments* comprise the *bridle, halter, watering-bridle, saddle, saddle-bags, saddle-blanket, nose-bag, lariat, currycomb, brush,* etc. *Infantry equipments* comprise the personal outfit of the soldier, excluding the arms proper and clothing. A set of equipments is called a *kit.* The standard kit includes the *knapsack, belts* and *plates, cartridge-box, bayonet-scabbard, haversack,* and *canteen.* The knapsack, haversack, and canteen are only used when marching. In future wars it is probable that an intrenching-tool will be added to the soldier's equipment. *Signal equipments* comprise the *flags, staffs, flying-torches, foot-torches, flame-shades, haversacks, telescopes,* etc. In the United States the term *equipments* is most commonly applied to an officer's outfit, including especially those articles made of gold lace and cord. The supplying of equipments to the Army, Navy, and National Guard has developed into a trade of magnificent proportions. In this line the house of Horstmann Brothers & Co. take the lead. It was founded in 1815 by William. H. Horstmann, of Cassel, Germany, who had previously learned the art of silk-weaving in France. He was the first to introduce the Jacquard machine into this country, and applied power to the production of gold lace and other narrow textile fabrics several years before the attempt was made in Europe. After the death of the elder Mr. Horstmann, the business was continued by his sons, William J. and Sigmund Horstmann, who in 1852 built their factory in Philadelphia. The present owners of the business represent the third generation. In the factory are produced narrow textile fabrics of all kinds, military and society goods and trimmings, including swords, metal-work, leather-work, gold and silver embroidery, and a great variety of minor and miscellaneous articles. The Messrs. Horstmann have paid special attention to a very fine class of goods for the equipment of officers, and their experience of over sixty years in the production of their specialties has enabled them to bring the goods to a degree of perfection in finish which challenges comparison with any of foreign manufacture. Adjoining the factory are the offices and salesrooms of the firm, who give employment to over 500 persons. Independent of the facilities for manufacturing all articles needed for the Army, Navy, and National Guard, they also import direct from the best sources such materials (the production of which has not yet been attempted in this country) as are required in the manufacture of the various articles in the line of equipment. See *Accoutrements.*

EQUITATION.—The art of riding. Military equitation—the principles of which are the same for all classes of cavalry, a uniform system existing throughout the country—is described as consisting in the skillful and ready application of the aids with which the rider guides and controls his horse in all his paces, and in a settled balance of the body which enables him to preserve a firm seat in every variety of movement. The aids in horsemanship are the motions and proper application of the bridle-hand and legs to direct and determine the turnings and paces of the horse. Military equitation may be divided into three parts: 1st. The complete instruction of the recruit upon a trained horse, from the earliest to the last lessons. 2d. The training of the horse by skillful and experienced men. 3d. The practice of the recruit and remount horse at close files in the elementary parts of field-exercise to prepare them for instruction in the troop or squadron. This science is indispensably requisite for the military horseman, in order that, being able to govern his horse by the aid of his legs and bridle-hand, he may have the right hand at full liberty for the use of his weapon, and be capable on all occasions, whether acting singly or in squadron, of performing his various duties with care. With this view, both men and horses should be constantly practiced in the exercise of such lessons as will enable them either to move in a compact body or to act singly or independently. The system of equitation now taught in the English army is that practiced at the riding establishment at Canterbury; and with the view of maintaining one system throughout the country, Commanding Officers of regiments are called upon from time to time to select non-commissioned officers and soldiers, and to send them to the riding depot at Canterbury for the purpose, as stated in the Queen's Regulations, of being practiced in the equitation exercises, and trained as riding instructors in their corps. See *Horsemanship.*

EQUITES.—The first of the three classes of soldiers in the Roman army who formed the cavalry. See *Equestrian Order.*

ERASED.—*Erased* or *eradicated,* in Heraldry signifies that an object is plucked or torn off, and showing a ragged edge; as opposed to *coupé* or *coupy,* cut, which shows a smooth edge. A tree plucked up by the roots is said to be eradicated.



Erased.

ERICIUS.—In Roman antiquity, a military engine, so named from its resemblance to a hedgehog. It was a kind of chevaux-de-frise, placed as a defense at the gate of the camp.

ERICSSON GUN.—A gun with a solid wrought-iron barrel, forged from a very superior iron, and reinforced with a series of thin washers, forced on with accurately determined tension by hydrostatic pressure. Upon the end of the breech is forged a solid flange, against which the washers abut. The washers are cut out of ⅝-inch boiler-plate, and extend forward to the middle of the chase, where a nut, embracing and screwed upon the chase, presses them against the solid flange, and into close contact with each other. The following are the particulars of this gun:

Total length	152 inches.
Length of reinforce of washers	96 "
Length of maximum diameter	42 "
Maximum diameter	47 "
Diameter of muzzle	22 "
Diameter of bore	13 "
Diameter of barrel under reinforce	28⅛ "
Thickness of hoops or washers	⅝ "
Total thickness of wall of gun	17 "
Weight	47,000 pounds.

ERMIN.—An order of knights instituted in 1450 by Francis I., Duke of Bretagne, and which formerly subsisted in France. The collar of this order was of gold, and composed of ears of corn in saltire, at the end of which hung the ermine, with the inscription *A ma vie.* The order expired when the Dukedom of Bretagne was annexed to France.

ERMINE.—A white fur with black spots; the reverse of which, or a black fur with white spots, also used in Heraldry, is called *contre ermine.* Ermine is commonly used to difference the arms of any member of a family who is connected with the law. A cross composed of four ermine spots is said to be a cross ermine.

Ermine.

ERRARD DE BAR-LE-DUC SYSTEM OF FORTIFICATION.—This system limits the minimum of the salient angles at 60°, adopts 290 yards as the maximum of the line of defense, and fortifies on the exterior polygon. This system is inferior to the Italian, although it stands at the head of the French school. See *Fortification.*

ESCADRON.—A term more ancient than the word *battalion,* first employed by the French writer Froissart to signify a troop of horse drawn out in order of battle.

ESCALADE.—In siege operations, escalading is a mode of gaining admission within the enemy's works. It consists in advancing over the glacis and covered-way, descending, if necessary, into the ditch by means of ladders, and ascending to the parapet of the curtain and bastions by the same ladders differently placed. The ladders are either procured on the spot, or are sent out with the siege-army. A convenient form is in pieces of twelve feet length, fitting end to end by means of sockets. A firing-party is usually told off to keep down the fire of the enemy upon the escaladers, especially a flank fire lengthwise of the ditch, which might sweep them off with terrible rapidity. The following is the outline of the method of escalade proposed by Colonel Jebb of the Royal Engineers: Ladders of suitable length for the enterprise are to be provided for scaling the scarp; the one proposed is three feet longer than the height of the scarp, so that the foot of the ladder being planted a pace or two from the bottom of the wall, the top may project far enough above the wall to enable the men to step from the ladder with ease in an upright position. An allowance of one ladder is made for every five feet of the face to be scaled; one hundred feet, for example, requiring twenty ladders. To each ladder from four to six men are assigned, according to its length. The ladders are borne in the usual manner on the shoulders of the men, two or three being placed on each side for this purpose. The ladders for scaling the scarp are assigned to the advance. A second set of less dimensions, for descending into the ditch only, are assigned to the support. The scarp-ladders are placed on the ground in line at some suitable point, with the proper intervals between them; the men to carry them, properly "told off," are drawn up in rear of them, and at the proper commands are marched to their places at the sides of the ladders, and raise them ready for the forward movement. Similar dispositions are made for the counterscarp-ladders, which are placed in line from 100 to 150 yards in rear of the others. At a given signal the whole are to move forward, covered by an advanced firing-party to keep down the fire of the work, and followed by a reserve. The scarp-ladders are let down into the ditch, the men descend, carry them across it, plant them against the scarp, and mount to the top. The top of the parapet gained, the men are to group themselves rapidly in *rallying-columns,* and proceed to clear the parapet by charging the assailed in flank. The support and reserve, in the mean time, are to follow on without loss of time to take their share in the action.

Troops properly exercised in *gymnastics* are capable of mounting high walls with arms and accouterments, and without the use of ladders. Most armies have realized the necessity of gymnastic training, and have adopted definite systems. The drawing shows a few combinations which might after a little practice assist recruits or poor climbers in mounting walls and entering the upper windows of houses. In all such attempts the light weights should be selected for the highest story, and the basement-story should consist of a sufficient number of men to render the support strong and the climbing easy. Precipitous rocks may be escaladed by grasping bushes and roots, or by planting the bayonet in the crevices of the rocks, in order to reach the top. Such escalades are very dangerous when an enemy defends the height, as heavy stones may be rolled down upon the assailants; but activity and ingenuity accomplish very much, as was shown by the French in the attack upon Fort Scharnitz near Innspruck. They tied their haversacks round their heads, and, protected by this buckler, they scrambled up the rocks, despite the stones precipitated upon them. And still later the difficult ascent at Alma was scaled by French troops in the face of Russian artillery and infantry.

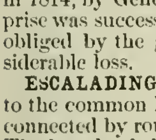
The most favorable time for a *surprise* is that of a winter night, when there is no moon. A long march may then be made without discovery, and the troops may arrive an *hour before day.* This is the propitious moment for the execution of the design. It is then that men sleep most profoundly; and it is at that hour the attacking force may begin in the dark and end the work by daylight; such favorable circumstances are much increased by heavy wind and rain during the night, as the clanking of arms and other inevitable noises made by the troops cannot be heard by the garrison, and the latter besides are more disposed to negligence. It is extremely important for the men to be able to recognize each other in the darkness, and the simplest means of doing so is to put the shirt outside the dress, or to tie a white band around the arm. The party must be furnished with petards, axes, and levers, to force open doors; with beams and ladders, to overthrow and scale walls. Hurdles and fascines are necessary to cross muddy ditches, or broad planks may be used as a substitute for hurdles. With fascines small ditches and pools are filled up. All these articles should be carried by the men from the last halting-place. Wagons and animals would lead to discovery, and are therefore left at a safe distance, while every precaution is taken to maintain silence in the assailing party. The soldiers should also not light their pipes, as the fire can be seen from a long distance in the dark. Barking dogs must be disposed of or quieted without the use of fire-arms, and every one must be on the alert.

The dispositions made for the attack will vary with circumstances, but in general it is well to divide the force into three parts: the first to penetrate into the city; the second to remain without and protect, if necessary, the retreat of the first; and the third to take such position as is most likely to prevent aid from reaching the enemy. When the first division has penetrated the city by escalade or otherwise, it surrounds at once some of the adjacent quarters, and holds the outlets of the principal streets, whilst detachments quickly open the gates to the troops outside, after having taken or killed the guards. As soon as the gates are opened, and sufficient numbers are at hand, the troops spread themselves in the city, after leaving good reserves upon which to retreat in case of check. The house of the Commandant, barracks, arsenal, and the guards of the interior are at once sought to prevent, if possible, any reunion of the defenders, and to paralyze all their efforts by the seizure of the Commanding Officer. If time and means of recovering from his stupor and concentrating his force in the interior of the city be left to the enemy, great risk will be run of being driven out, as the attacking force is necessarily everywhere weak, from the great number of points occupied. The famous example of Cremona, where Prince Eugene, after having made himself master of a great part of the city, and after having seized Marshal Villeroi, who commanded there, was nevertheless then driven out by the defenders, shows that all is not lost to the defenders when the enemy has seized the exterior posts. Another example may be cited in the surprise of Bergen-op-Zoom in 1814, by General Graham, where, although the surprise was successful, yet the assailants in the end were obliged by the garrison to surrender after very considerable loss.

ESCALADING LADDERS.—Frames of wood, similar to the common ladder, consisting of two side pieces, connected by rounds or steps, and sometimes by rope. The length of the ladders should be relative to that of the works or the walls to be escaladed. They are sometimes made in two or three parts, so that they may be more conveniently carried. There are two kinds of escalading ladders; those in lengths provided by Government with other engineers' stores, and those of an impromptu kind, made for the occasion. The first description consists of ladders about 12 feet in length, which fit into one another, so that each joint will give an effective length of 10 feet. The second description of ladder is in one length, which is difficult of carriage. In India, escalading ladders are made of two longitudinal pieces of bamboo, the transverse pieces of wood being let into the bamboo, and bound round it with strong rope. They are of two sizes, 26 feet and 14 feet long. See *Escalade*.

ESCALE.—A machine used in ancient times to pry the petard. Now obsolete. See *Petard*.

ESCALOP-SHELLS.—These are often used in Heraldry to signify that the bearer has made many long voyages by sea. As the Pilgrim's emblem, they were commonly given to those who had been to the Crusades; they came to be regarded as indicating either that the bearer or his ancestor had been a Crusader. The escalop-shell was the emblem of St. James the Great, and is generally met with in churches dedicated to him. The more ordinary form of the name is *scallop-shell*. See *Heraldry*.



Escalop-shells.

ESCARP.—In fortification, the surface of the ditch next the rampart, the surface next the enemy being termed the *counterscarp*. See *Scarp*.

ESCARPMENT.—Ground cut away nearly vertically about a position, in order to render it inaccessible to the enemy. See *Ditch* and *Scarp*.

ESCOPETTE.—A carbine, an improvement on the early hand-culverins or *sclopos*.

ESCORT.—A body of troops attending an individual as a guard. The term is also applied to a guard placed over prisoners on a march, to prevent their escape, and to the guard of a convoy of stores.

ESCORT OF HONOR.—Escorts of honor are detailed for the purpose of receiving and escorting personages of high rank, civil or military. The troops for this purpose are selected for their soldierly appearance and superior discipline. The escort forms in line, bayonets fixed, the center opposite the place where the personage presents himself, with an interval between the wings to receive him and his staff, the band on the flank of the escort toward which it will march. On the appearance of the personage, he is received with the honors due to his rank. When he has taken his place in the line, the escort is formed into column of companies, platoons, or fours, and takes up the march. On leaving, the escort line is formed, and the same honors are paid as before. When the position of the escort is at a considerable distance from the point where the person is to be received, as, for instance, where a court-yard or wharf intervenes, a double line of sentinels is posted from that point to the escort, facing inward; the sentinels successively salute as he passes, and are then relieved and join the escort. An officer is appointed to attend him, to bear such communications as he may have to make to the Commander of the escort. See *Funeral Honors*.

ESCORT OF THE COLOR.—The military ceremony of sending for and receiving the colors of a battalion. The battalion being in line, the Colonel after bringing the battalion to *carry arms* details a company, other than the color-company, to receive and escort the colors to their place in line. The escort is formed in column of platoons; the band in front, the Color-bearer between the platoons. The escort is then put in march, without music, arms at a *right shoulder*. On approaching the Colonel's quarters, the escort is halted and formed in line facing towards them, the band on the right, the Color-bearer in the line of file-closers. The moment the escort is in line, the Color-bearer, preceded by the First Lieutenant and followed by a Sergeant of the escort, goes to receive the color. When the Color-bearer comes out, followed by the Lieutenant and Sergeant, he halts before the entrance; the escort *presents arms*, and the trumpeters, or field-music, sound *to the color*. The Captain then causes the arms to be *carried;* the Lieutenant and Sergeant return to their posts, and the Captain breaks the company into column of platoons; the Color-bearer places himself between the platoons. The escort marches back to the battalion to the sound of music, in quick time, and in the same order as above, the guide to the left. The march is so conducted that, when the escort arrives at fifty yards in front of the right of the battalion, the direction of the march may be parallel to its front; when the color arrives opposite its place in line, the Captain forms line to the left and halts; the Color-bearer, passing between the platoons, advances and halts twelve yards in front of the Colonel. The Color-bearer having halted, the Colonel, who posts himself twelve yards in front of the center of his battalion, faces about, commands, 1. *Present*, 2. ARMS, resumes his front and salutes; the trumpeters, or field-music, sound *to the color*, and the Color-sergeant returns the color-salute. The Colonel then faces about, brings the battalion to a *carry*, after which the Color-bearer takes his place in the color-guard. The escort *presents* and *carries arms* with the battalion at the command of the Colonel, after which the Captain forms it again in column, and marches it to its place in line, passing around the left flank of the battalion. The color is escorted from the parade-ground of the color-company to the Colonel's quarters, by the color-guard.

The ceremony of escorting the *standard* is as follows: The regiment being in line, the Colonel, after bringing the regiment to *carry saber*, details a company, other than the color-company, to receive and escort the standard to its place in line. The escort is formed in column of platoons; the band in front, the Standard-bearer between the platoons. The escort is then put in march, without music. On approaching the Colonel's quarters, the escort is halted and formed in line facing toward them, the band on the right, the Standard-bearer in the line of file-closers. The escort being in line, the First Lieutenant, Standard-bearer, and the Right Principal Guide dismount in front of the Colonel's quarters, their horses being held by a trumpeter; the Standard-bearer, preceded by the First Lieutenant and followed by a Sergeant of the escort, then goes to receive the standard. When the Standard-bearer comes out, followed by the Lieutenant and Sergeant, they halt before the entrance and mount, the Lieutenant on the right, Sergeant on the left; the trumpeter returns to his post; the Captain then commands, 1. *Present*, 2. SABER; the escort *presents saber*, and the trumpeters sound *to the standard*. The Captain then causes the saber to be *carried*; the Lieutenant and Sergeant return to their posts, and the Captain breaks the company into column of platoons; the Standard-bearer places himself between the platoons. The escort marches back to the regiment to the sound of music, and in the same order as above, the guide to the left. The march is so conducted that, when the escort arrives at fifty yards in front of the right of the regiment, the direction of the march may be parallel to its front; when the standard arrives opposite its place in line, the Captain forms line to the left and halts; the Standard-bearer, passing between the platoons, advances and halts twelve yards in front of the Colonel. The Standard-bearer having halted, the Colonel, who, posts himself twelve yards in front of the center of his regiment, faces about, commands, 1. *Present*, 2 SABER, resumes his front and salutes; the trumpeters sound *to the Standard*, and the Standard-bearer returns the salute of the standard. The Colonel then faces about, brings the regiment to a *carry*, after which the Standard bearer, passing through the interval to the left of his company, wheels to the left about, and takes his place in the guard of the standard. The escort *presents* and *carries sabers* with the regiment at the command of the Colonel, after which the Captain forms it again in column, and marches it to its place in line, passing around the left flank of the regiment.

ESCOUADE.—A term which signified, in the old French service, the third part of a company of foot or a detachment. Companies were divided in this manner for the purpose of more conveniently keeping the tour of duty among the men. We have corrupted the term and call it a *squad*.

ESCOUAGE.—An ancient feudal tenure by which the tenant was bound to follow his lord to war or to defend his castle. The term is also used for the commutation of personal service into a money payment, such as is observed in the case of a substitute where compulsory service is enacted.

ESCUTCHEON OF PRETENSE.—A small shield placed in the center of the larger one, and covering a portion of the charges on the latter, in which a man carries the arms of his wife when she is the heiress of her family. It is said to be carried *surtout*, or over-all. Sometimes also a shield over-all is given as a reward of honor; thus, the Earl of Stirling did bear two coats quarterly, and over all an inescutcheon of Nova Scotia, because he was the first planter of it. Usually written *Inescutcheon*.

ESPADON.—In old military works, a kind of two-handed sword, having two edges, of a great length and breadth; formerly used by the Spanish. Recently the term has been applied to all double-edged weapons.

ESPAULIERE.—A defense for the shoulder, composed of flexible, overlapping plates of metal, used in the fifteenth century; the origin of the modern *epaulette*.

ESPINGARD.—An ancient name for a very small gun under a 1-pounder, and in use as early as the fourteenth century. Also written *Epingare*.

ESPINGOLE.—A kind of blunderbuss which, in early times, was loaded with several balls; the charges were separated from each other by tampions in which holes were made, and thus the balls were fired in succession. See *Blunderbuss*.

ESPLANADE.—In fortification, the open space intentionally left between the houses of a city and the glacis of its citadel. It requires to be at least 800 paces broad, that the enemy, in case of his getting possession of the town, may not be able to assail the citadel under cover of the nearest houses. For this purpose the citadel must command the esplanade, and be able to send a direct fire into the streets opening upon it. In old works on fortification the term is often applied to the glacis of the counterscarp, or the slope of the parapet of the covered-way towards the country. See *Fortification*.

ESPONTOON.—A sort of half-pike, about 3 feet in length, used in the seventeenth century. The Colonels of Corps, as well as the Captains of Companies, always used them in action. This weapon was also used by officers in the British army.

ESPRINGAL.—In the military engineering of the days before the introduction of gunpowder in European warfare, a machine for throwing missiles. These missiles were either large darts called *muchettes*, or arrows winged with brass, and called *viretons* from their whirling motion when shot forth. Also written *Springal*.

ESPRIT DE CORPS.—A term generally used among military men. It may not improperly be defined a laudable spirit of ambition which produces a peculiar attachment to any particular corps, company, or service. Officers, without descending to mean and pitiful sensations of selfish envy, under the influence of a true *esprit de corps* rise into an emulous thirst after military glory. The good are excited to peculiar feats of valor by the sentiments it engenders, and the bad are deterred from ever hazarding a disgraceful action by a secret consciousness of the duties it prescribes.

ESQUIRE.—The Esquire in Chivalry was the Shield-bearer or Armor-bearer to the Knight, and hence was called *Armiger* in Latin. He was a candidate for the honor of knighthood, and thus stood to the Knight in the relation of a novice or apprentice, pretty much as the page did to him. In this capacity he was spoken of as a Bachelor, just as the Knight Bachelor came latterly to be distinguished from him who had already attained to the higher honors of Chivalry. When fully equipped, each Knight was attended by two Esquires. The Esquire was a gentleman, and had the right of bearing arms on his own shield or escutcheon, which is surmounted by a helmet placed sideways, with its visor closed, to distinguish him from a Knight or Nobleman. He had also the sword, the emblem of Chivalry, though he was not girded with the knightly belt. His spurs were silver, to distinguish them from the golden spurs of the Knight; and when the King created Esquires of old, it was by putting silver spurs on their heels, and collars of SS round their necks. Those who received this honor directly from the Sovereign were in general the Esquires for the King's body, or those whose duty it was to attend him in his capacity of a Knight; an office now nearly obsolete. Tenants of the Crown who held by Knight's Service were a class of Feudal Esquires generally supposed to correspond to the simple *Ritters* or Knights of Germany, as opposed to the *Ritters* who were *geschlagen* or dubbed, inasmuch as these English Esquires were entitled to claim the rank of knighthood. Though the title of Esquire has now come to be given without discrimination to all persons above the rank of a tradesman or shop-keeper, the following seem to be those whose claim to it stands on the ground either of legal right or of long-established courtesy: 1. All the untitled sons of Noblemen; 2. The eldest sons of Knights and Baronets; 3. The sons of the younger sons of Dukes and Marquises, and their eldest sons. All these are Esquires by birth. Then there are Esquires by profession, whose rank does not descend to their children; and Esquires by office—e.g., Justices of the Peace—who enjoy the title only during their tenure of office. To the former class belong Officers in the Army and Navy, Barristers, and Doctors of Law, and Doctors of Medicine, but not Surgeons.

ESSEDARII.—In Roman antiquity, gladiators who fought in a heavy kind of chariot called *esseda* or *essedum*. The esseda differed from the *currus* in being open before instead of behind, and in this way the owner was enabled to run along the pole, from the extremity of which, or even from the top of the yoke, he discharged his missiles with surprising dexterity.

ESTABLISH.—A technical phrase to express the quartering of any considerable body of troops in a country. Thus it is common to say the army took up a position in the neighborhood of ——, and established the headquarters at ——. The term is also used in the sense of posting guides, markers, etc.

ESTABLISHMENT.—The extent, *matériel*, and *personnel* allowed to an army in peace or war time; in the latter case it is regulated according to the exigencies of the service, which being much greater during war than peace has given rise to the distinction of a *war* and a *peace establishment*.

ESTACADE.—A dike constructed of piles in the sea, a river, or a morass, frequently used to check the approach of an enemy.

ESTAFETTE.—A military courier who is sent express from one part of an army for a given time.

ESTIMATE.—A computation of the probable expense of any project or charges to be incurred, framed on any recognized data, derived from previous experience, such as the yearly military and other estimates of the country.

ESTIMATION OF DISTANCE.—In all circumstances where ordnance is employed, whether in the field or on the water, a knowledge of the distance is the essential element of correct practice. When considerable, it is usually estimated very vaguely; but the necessity of knowing it as correctly as possible at long ranges is greater than when the trajectory is nearly flat as in short ranges, elevation being given according to the distance, and inaccuracy increasing with length of range. At considerable distances, also, there is more leisure and opportunity, as well as greater necessity, for determining those distances with precision, while in closer action all that is required is to be certain that the enemy is within range at level. Distances may be estimated by several methods: 1st. By sight. 2d. By means of topographical maps. 3d. By the aid of special instruments for measuring angles. 4th. By the propagation of sound.

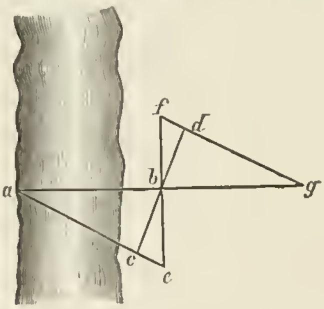
As in the excitement of action the employment of instruments is very difficult, it is desirable that every officer and soldier should be able to judge of distances by the eye. Under conditions favorable to observation, long practice enables an observer to estimate immediately and quite closely the position of an object within the distance of 500 yards. Beyond this limit, the variable condition of the atmosphere, as well as the form and nature of the ground, lead the most practiced observer into considerable error. A knowledge of the parts of objects visible at certain distances is necessary; but as this will vary with the power of the eye, each must, by comparison and reflection, establish a standard of his own. In ordinary weather, good sight admits of—1st. Counting the windows of a house at 4300 yards; 2d. Perceiving men and horses at 2200 yards; 3d. Distinguishing clearly infantry from cavalry at 1300 yards; 4th. Seeing the movements of men at 800 yards; 5th. Distinguishing the head and hat of a man at 550 yards; 6th. Seeing faces and principal parts of uniform at 300 yards. Objects always appear too near when seen distinctly outlined or against a bright background, as when the observer has the sun at his back, or when the air is particularly clear, as after a rain. Distances are underestimated also when the ground is uniform and offers no prominent points for reference. On the contrary, objects appear too reomte when obscure and indistinct. This occurs if the sun be in one's face, and if the weather be cloudy or foggy. Distances are also overestimated when the ground is undulating, cut by ravines, or covered with trees or dwellings.

Distances are most frequently estimated by special instruments. The simplest of these instruments are stadias and thread-micrometer or double-image telescopes, which give the unknown distance by observation of the apparent height of a man on foot or on horseback, placed near the distant point. None of these allow the estimation of distances greater than 1600 yards, and the results of observation are always uncertain. The *stadia* consists of a piece of sheet-metal with an isosceles triangle cut out of it, the sides of which are graduated parallel to its base; a slide moves along the length of the plate. The base of the opening is perpendicular to the sides of the instrument, and represents the apparent height of a man at a certain distance. The graduations may be determined by observation or by calculation, assuming a given height for the infantry or cavalry soldier.

Instruments constructed on the principal of the thread-telescope have been tried, but with little success for actual service, and especially have not been found sufficient for artillery-firing. During the last twenty years many instruments for measuring distances have been devised. Nearly all are concerned with the rapid solution of a triangle, one of whose sides is the distance to be determined, and another is a base of known length. The instruments of Goulier and Gautier, used in France, and that of Nolan, in England, are good examples. Of these, Gautier's has been experimented with in the United States. Gautier's telemeter is simple and portable, consisting of a tube, similar to one barrel of a field-glass, containing lenses and two mirrors placed at an angle of about 45 degrees with each other; but it requires an accurate base and delicate management. With practice, however, an observer can estimate with more than ordinary promptitude and precision the distance to be obtained. Nolan's range-finder consists of two instruments for measuring angles; they are mounted on tripods and are placed at the extremities of a measured base-line, which is perpendicular to the range. With the data thus obtained, recourse is had to a *reckoning-cylinder*, from which the distance is read. A base of from 30 to 40 yards will be used for ranges of 3000 yards and over. The Weldon range-finder, lately introduced, will, it is thought, prove a useful instrument for open ground. In this system are used a base, proportional to the sides of the triangle which converge on the object from the extremities of the base, and two simple plate-glass prisms, the angles of which are constructed accurately to have certain fixed values, and whose backs are silvered to act as mirrors. Two observers, each with a prism, place themselves on a line, the general direction of which is perpendicular to that of the object from them. Each then moves along this line till he brings the reflection of the object in the prism and the eye of the other observer, seen direct, in the same vertical line; the distance between the observers at this instant, multiplied by a certain factor, which depends on the angles of the prism, gives the distance of the object from either observer.

To estimate distances by the velocity with which sound is transmitted in the air, it is necessary to note the instant at which the flash of a gun or the explosion of a shell is seen, and the instant at which the report of the same is heard at the point of observation.

This is a simple and rapid method, but is not always accurate. A watch, or any instrument constructed to record time, can be employed. The *Le Boulengé telemeter* is such an instrument. It consists of a glass tube, filled with a non-freezing, transparent liquid; within this is a metal index, which, when the tube is vertical, descends with a slow, uniform motion. The tube is placed in a brass case, to which a scale is attached. The scale shows the distance, in yards, through which sound will travel in air during the time required for the index to descend to any division. The effect of temperature on the liquid and index is such that the velocity of the index is influenced in the same proportion as the velocity of sound, the instrument thus being self-adjusting. For pieces used in the siege and sea-coast services the ranges do not have to be determined under the same circumstances as in the field. The position of siege-batteries can be found at leisure, either from maps or by the instruments used ordinarily by surveyors. In the sea-coast service, the distance of a vessel can be determined by its position relative to known points on land, or to buoys that have been carefully located for that purpose. A simple instrument for taking horizontal angles, or any of those that are applied in the field, can be employed. The *plane-table* may be used advantageously for recording the striking-point of a shot or the position of a vessel. The tables are placed at each end of a base-line, so taken that the tables shall have a clear view of the object, of each other, and of the gun; the lines joining them with the object should intersect at as near a right angle as possible. The gun may be at any point of the base-line, or entirely without it. The distance can be calculated from the data obtained, or the object may be plotted and the distance measured by a scale.



Any of the following methods may be employed to estimate the breadth of a river, or any impassable distance, without instruments: 1st. Assume *dc* in any direction, and make *bc* = *bd* (*ab* being as nearly perpendicular to the banks as practicable); then, locating *e* on *ac* produced, make *bf* = *be*; join *f* and *d* and prolong *fd* to *ab* at *g*; then *bg* = *ab*. 2d. Produce *be* until the angle *bea* = 45°; then *be* = *ab*. 3d. Without reference to figure, the following methods may be used according to the location of the distance to be measured with respect to the surrounding country. (*a*) Let AB equal the distance to be measured. Produce AB to any point, D, and bisect BD in C. Through D draw D*a*, making an angle with DA, and take D*c* and D*b* = DC and DB respectively. Join B*c*, C*b*, and A*b*. Through E, the intersection of B*c* and C*b*, draw DEF, meeting A*b* in F. Join BF, which being produced will meet D*a* in *a*; then *ab* = AB. (*b*) From any point, C, draw any line *c*C and bisect it in D; take any point, E, in the prolongation of AC and draw the line E*e*, making D*e* = DE. In like manner take any point, F, in the prolongation of BC, and make D*f* = DF. Produce AD and *ec* till they meet in *b*; then A*b* = AB. (*c*) At any point, E, in AB drop a perpendicular and on it make E*b* = 50 feet, and EF = 60 feet. Trace a line through F perpendicular to EF. Then plant pickets at M and N, so that M, G, and B will be in the same right line; as also the points N, G, and A. Measure the distance (*d*) between M and N, then the distance required equals 5*d*.

ESTOC.—The long narrow sword intended for thrusting rather than cutting. The expression *frapper d'estoc et de taille* can only apply to the long broad-bladed sword, inasmuch as the blade of the rapier was suitable only for thrusts. The rapiers of the estoc shape were not in use before the reign of Charles V., in whose time the modern art of fencing seems to have originated. The estoc in Elizabethan times was generally called a *tucke*.

ESTOILE.—In Heraldry, a term differing from the mullet by having six waved points; the mullet consisting of five plain points. See *Heraldry*.

ESTRADIOTS.—Grecian and Albanian horsemen, some of whom were employed in the Italian wars by Charles VIII.; their favorite weapon was the zagaie. Besides this they had a broad-sword and club slung on the bow of the saddle, with sleeves and gauntlets of mail. Also written *Stradiots*.

ESTRAMACON.—A sort of two-edged sword used in ancient times. The term also expresses a blow with the edge of a sword.

ETAPPEN.—A Department which originated in the Prussian Military Railway Organization, and which was first formed in 1867, and revised in 1869; subsequently certain changes were made during the war of 1870–71. The object of this Department is to relieve the Commander-in-Chief and Field Army of all responsibility for their communications in the rear. Etappen Commissions a reappointed to each loading and unloading station, to which a Field Officer as Commandant, an Adjutant, Control Officer, Railway Officials, and Civil Government Officials, are attached. These officers supervise all local arrangements for loading or unloading, forwarding, feeding, billeting, etc. One of the officers originally appointed to this Department was an Inspector of Etappen; he was supposed to be a march in rear of headquarters, superintending all necessary arrangements, but he had no authority over the Civil Departments with which he came into contact. In 1870 the Inspector was found to have too much to do, and a considerable amount of friction ensued. The Commissariat Officer attached received orders from an Inspector and from his own Chief. The Railway Subordinate was liable to some ten different Chiefs, and the whole railway arrangements were half military, half civil. New regulations were subsequently introduced which extended the powers of the Inspector of Etappen. The official title is "Inspector of Etappen and Railways." He is present with headquarters, and under him are placed the Medical Department, Commissariat, Post-office, and Telegraphs, under responsible heads. The general principle or idea is this: A line is imagined to be drawn through the headquarters. All in front belongs to the active army, all in rear to the Etappen Inspector. The Quartermaster General's Department has to do with both. To take in the whole of the Prussian Railway Control ,it would be necessary to describe in full the system pursued, which space will not admit. An Étappen Department has been raised in the French army after the Prussian system.

ETAT MAJOR.—The Staff of an army, including all officers above the rank of Colonel; also, all Adjutants, Inspectors, Quartermasters, Commissaries, Engineers, Ordnance Officers, Paymasters, Surgeons, Signal Officers, Judge Advocates; also, the non-commissioned assistants of the above officers.

ETOILES.—Small redoubts which are constructed by means of angles rentrant and angles sortant, and have from 5 to 8 salient points. This species of fortification has fallen into disuse, and is superseded by square redoubts, which are sooner built and are applicable to the same purpose of defense.

ETOUPILLE.—An inflammable match, composed of three threads of very fine cotton, which is well steeped in brandy mixed with the best priming gunpowder.

EUPHORBIA TIRUCALLI. — This plant is much used in making hedges in India. It is an evergreen. The wood makes very fair charcoal for gunpowder purposes, but it is not equal to that derived from the urhur or dhall-bush. In Bengali it is called *lunka sij*, and in Hindustani, *sendh*.

EUREKA PROJECTILE.—A projectile consisting of a cast-iron body in one piece, with a brass sabot; the sabot is an annular disk intended to move on the frustum of a cone with the expanding cup in rear to take the grooves. See *Projectiles*.

EUTHYTONE.—A very ancient machine of war, described by Heron, Philon, and Vitruvius. It was a variety of the catapult.

EVACUATE.—To withdraw from a town or fortress, in consequence either of a treaty or a capitulation, or of superior orders.

EVAGINATION.—A common expression for the unsheathing or drawing out of a sheath or scabbard.

EVANS MAGAZINE-RIFLE.—A novel rifle of some merit, but no longer manufactured. It differed from most magazine-guns in having no spiral spring for the purpose of feeding the cartridges through and from the magazine to the breech-mechanism, and in having its magazine located in the stock of the arm. The magazine consisted of a cylinder of forged iron, running from the breech to the butt-plate; around the inner circle of this cylinder was affixed, in the form of a spiral, a flat wire of the proper conformation. Into this cylinder with its fixed spiral was introduced a shaft of fluted or grooved iron, this shaft being revolved by movement of the lever in the breech-mechanism. The cartridges were introduced into the magazine through the butt-plate; with the introduction of each cartridge the breech-mechanism was moved, thus carrying forward the cartridges until the magazine was filled. The cartridges in the magazine were in separate cells, and could not come in contact with each other, thus precluding any possibility of discharge; while in all spiral-spring magazine-guns the cartridges press one against the other, thus rendering a premature discharge possible.

The system of feed in this gun strongly resembled the Archimedean screw. The magazine carried 26 rounds of cartridges of 2 inches in length, and could be loaded in one half of a minute, and the entire magazine of 26 rounds discharged at will, in from 15 to 20 seconds, thus embracing a very great repeating capacity. This arm could be fired 20 rounds per minute, while used as a single-loader, introducing the cartridges into an aperture at the side of the receiver at the breech; or it could be fired 20 rounds per minute, holding the magazine full and in reserve, by introducing cartridges into the magazine at the butt, as each cartridge was discharged. The weight of the gun was 9½ pounds, and length of barrel 30 inches. The carbine weighed 8½ pounds, and had a barrel 22 inches in length. See *Magazine-gun*.

EVENING PARADE.—The daily parade at or about sunset. When troops are encamped, the signal for evening parade is given from the park of artillery, by the discharge of a piece of ordnance, called the *evening* or *retreat gun*. See *Dress Parade*.

EVIDENCE.—All that which makes clear, demonstrates, or ascertains the truth of the very fact or point in issue. Evidence may be considered with reference to (1) the *nature* of the evidence; (2) the *object* of the evidence; (3) the *instruments* of evidence; and (4) the *effect* of evidence. As to its *nature*, evidence may be considered with reference to its being (1) the primary evidence; (2) secondary evidence; (3) positive; (4) presumptive; (5) hearsay; and (6) admissions. 1. *Primary evidence*. The law generally requires that the best evidence the case admits of shall be produced. 2. *Secondary evidence* is that species of proof which may be admissible on the loss of primary evidence. Before it is admitted, proof must be made of the loss or impossibility of obtaining the primary evidence. 3. *Positive evidence* is that which, if believed, establishes the truth of a fact in issue, and does not arise from any presumption. Evidence is positive when the very facts in dispute are communicated by those who have actual knowledge of them by means of their senses. 4. *Presumptive evidence* is that which is not direct, but where, on the contrary, a fact which is not positively known is presumed from one or more other facts or circumstances which are known. 5. *Hearsay* is the evidence of those who relate not what they know themselves, but what they have heard from others. As a general rule, hearsay evidence of a fact is not admissible. But evidence given on a former trial by a person since dead is admissible, as is also the dying declaration of a person who has received a mortal injury. 6. *Admissions*, which are the declarations made by a party for himself or those acting under his authority. These admissions are generally evidence of facts declared, but the admissions themselves must be proved.

The *object* of evidence is to ascertain the truth between the parties. Experience shows that this is best done by the following rules, which are now binding in the law: 1. The evidence must be confined to the point in issue; 2. The substance of the issue must be proved, but only the substance is required to be proved; 3. The affirmative of the issue must be proved. A witness, on being admitted in Court, is first subjected to the examination of the party in whose behalf he is called. This is termed the *examination in chief*. The principal rule to be observed by the party examining is that leading questions are not to be asked. The witness is then cross-examined by the other party. The object of cross-examination is twofold: to weaken the evidence given by the witness as to the fact in question, either by eliciting contradictions or new explanatory facts; or, secondly, to invalidate the general credit of the witness. In the latter case it is a general rule that a witness may refuse to answer any question if his answer will expose him to criminal liability. The general practice of English Courts also seems to authorize his refusal to answer any question which will disgrace him. The credit of a witness may likewise be impeached by the general evidence of others as to his character; but in this case no evidence can be given of particular facts which militate against his general credit. Witnesses are excluded from giving evidence by: 1. Want of reason or understanding; 2. Want of belief in God and a future state; 3. Infancy; 4. Interest. Besides witnesses, records and private writings are also *instruments* of evidence.

Records, in all cases where the issue is *nul tiel reord*, are to be proved by an exemplification duly authenticated; that is, an attestation made by a proper officer, by which he certifies that a record is in due form of law, and that the person who certifies it is the officer appointed by law to do so. In other cases an examined copy, duly proved, will in general be evidence. Private writings are proved by producing the attesting witness, or, in case of his absence, death, or other legal inability to testify, as if, after attesting the paper, he becomes infamous, his handwriting may be proved. When there is no witness to the instrument, it may be proved by evidence of the handwriting of the party, by a person who has seen him write, or in a course of correspondence has become acquainted with his hand. Parol evidence is admissible to defeat a written instrument on the ground of fraud, mistake, etc., or to apply it to its proper subject matter, or, in some instances, as ancillary to such application, to explain the meaning of doubtful terms, or rebut presumptions arising extrinsically. But in all cases the parol evidence does not usurp the place or arrogate the authority of the written instrument.

EVOCATI.—A class of soldiers among the Romans who, after having served their full time in the army, entered as volunteers to accompany some favorite General. Hence they were likewise called *Emereti* and *Beneficarii*.

EVOCATION. — An old religious ceremony commonly observed among the Romans at the commencement of a siege, wherein they solemnly called upon the gods and goddesses of the place to forsake it and come over to them. When any place surrendered, they always took it for granted that their prayer had been heard.

EVOLUTIONS.—The movements of troops in order to change position. The object may be to maintain or sustain a post, to occupy a new post, to improve an attack, or to improve a defense. All such movements as marching, counter-marching, route-marching, changing front, forming line, facing, wheeling, making column or line, making echelon or square, defiling, deploying, etc., come under the general heading of evolutions. The word *maneuver* signifies also movements of troops or entire corps in war executed with general views; and by some writers it is confined to that signification, and the word *evolution* is made to designate the particular means, or the elements of maneuvers. Maneuvers, according to Bardin, are operations in war, whether really before an enemy or simulated on a field of exercise. Their precision and aptness depend upon the skill of the General; the intelligence of his Aides-de-Camp; upon the Chiefs of Battalions and their Adjutants, and the General Guides. Evolutions and maneuvers are, however, often applied in the same sense, and indeed it may well be questioned whether there be any propriety in retaining in books of instruction evolutions which are not used as maneuvers against an enemy. The vicious idea that tactical evolutions are not used in war is by no means uncommon, and has frequently caused the loss of battles. It is true that the number of maneuvers used in combats is limited, and that those which are needed can only be judiciously applied by keeping in view moral and physical requirements. The judicious tactician will, therefore, in war eschew deployments, which cause the soldier to turn his back towards an enemy; counter-marches; forming a battalion on the right or left by file into line, and some other movements suited only to parades. One of the most hazardous maneuvers is the formation of columns of great depth and deploying those columns when too near the enemy.

The column is an order of march and maneuver, rarely an order of battle. When beyond the range of cannon, and at a distance from the line of battle to be occupied, if the enemy approach and time permits, it is necessary to close in mass, in order to hold the troops in hand for all possible dispositions. So, in marches near the enemy the columns should march at half-distance, when roads permit, in order that they may be less elongated and all the troops be ready to act promptly. If surprised in this order by the necessity of forming immediately forward into line of battle, or, if without being under this pressing necessity, there is between us and the enemy ground admitting an easy march in line of battle, the column ought to execute forward into line, according to the principles of the tactics. This movement is more prompt and greatly better than closing column in mass in order to deploy afterward. In the first case troops only pass over one side of the triangle, whilst by massing the column to deploy afterward they must pass over two sides by a complicated maneuver, which is dangerous from the beginning. In general, it is necessary to shun as much as possible the deployment of great massed columns, for this movement is badly executed even in exercises. It can only be performed far from the enemy, and it is even there inconvenient. It should be renounced in all formations whose object is to take the enemy in flank or reverse, if he be sufficiently near to take measures to prevent success. In that case the formation of the close columns in mass upon the right or left into line of battle is a necessary maneuver. This movement, as Marshal Bugeaud suggests, is most important in war. It would have an influence upon battles by the simplicity and rapidity of its execution, and accidents of ground would often be found to conceal the movement from the enemy. It admits of an attack in echelons of battalions against an enemy being commenced as soon as one battalion or the half of a battalion has formed on the right or on the left of the line of the enemy. It also offers the advantage of giving to the line, with the greatest facility, every form that may be wished, and protecting the successive formations by a mass that may be disposed of at pleasure, whether at the extremity of the line to form square against cavalry, or to occupy in advance upon the right or left a commanding position, protecting the flanks of our line. When circumstances, then, compel a march in heavy mass, it is better to present to the enemy a flank of columns, in order to deploy them by formations on the right or on the left into line of battle. When a line has to pass over a great distance, it is commonly formed into columns of attack. The formation by company in column, in rear of the Grenadiers of each battalion, is preferred by Marshal Bugeaud, because it is thus easier to make good dispositions against cavalry. The Grenadiers of each battalion make a half-wheel, and each battalion, after being closed in mass, forms square. But neither the column by companies nor divisions should be used within range of cannon, whenever there is a possibility of marching in line of battle. It is time that the fact should be admitted that although the moral effect of the column may be considerable, yet this may be paralyzed by a little maneuvering on the part of the enemy's *line*, which would necessarily obtain great advantage from the superiority of its fire. Small columns, at distances of three battalions from each other marching under cover of the line, may render great services. They would be ready promptly to fill the holes made in the line of battle, and the best means of doing this would be to take the enemy in flank who had pierced them, whenever they could. It is desirable that these columns should each not exceed a half-battalion, and that they should be commanded by energetic officers.

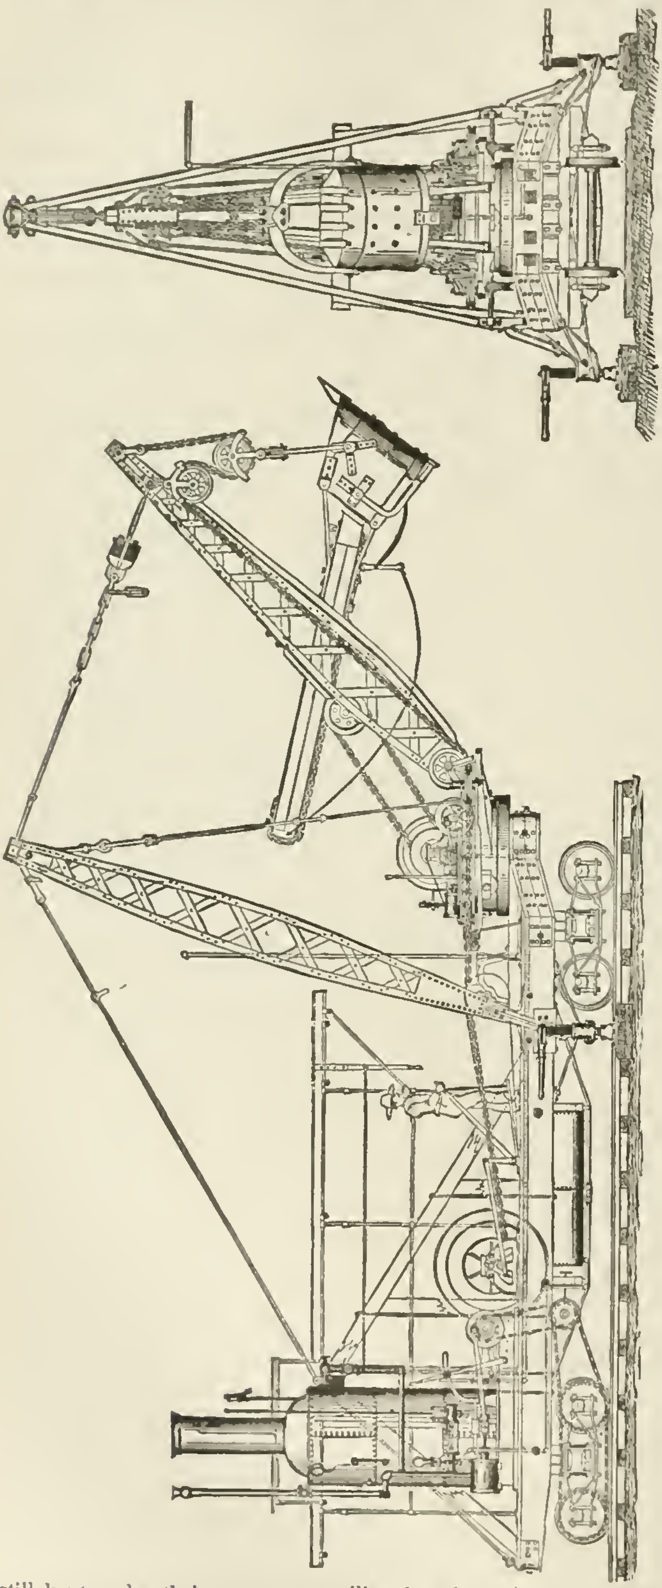
The depth of the column adds nothing to the strength of the first battalion composing it, and diminishes that of the mass. It is, then, vicious to employ more than one battalion, except in the small number of cases where it is necessary to fight in mass, as in carrying a bridge, a defile, an intrenchment, a breach, etc. The other battalions ought to follow at such a distance that they may sustain the attacking battalion without sharing in its disaster or rout, if such should take place. With an interval the Chiefs of Battalions have time to prepare their troops and make necessary dispositions; with a single mass the disorder at the head of the column is communicated to the rear almost as readily as an electric spark. Flank marches, in presence of the enemy, ought always to be made in open column. In this order we are always ready to fight by a simple wheel of each subdivision of the column. Nothing is deranged in the order of battle, whatever may be the strength and number of the lines. Without derangement an excellent disposition may also be made against cavalry. The column will be halted, and each battalion will be closed in mass upon its Grenadiers, who make a half-wheel. The Field-officers, Staff, and the officers of Grenadiers will be previously warned. Each battalion will form then Marshal Bugeaud's square. The first order will be resumed by taking distances by the head of each battalion; the Grenadiers retaking their direction at once. If deep columns are condemned as an order of attack, those barbarous columns employed in some of the last battles of Napoleon, and particularly at Waterloo, ought to be condemned still more. That column, which appeared to announce the decline of art, consisted in employing all the battalions of a division one behind the other, and thus marching towards the enemy. Every column has for its object to pass rapidly, and without confusion, into the order of battle, to pass over lightly a given space, and to make prompt dispositions against cavalry. The column against which these remarks are made does nothing of that kind, and if it be attacked upon its flanks, whether by cavalry or infantry, it cannot fail to be destroyed. The line of battle is the true order of battle. It is also the best order of march when in range of cannon and not exposed to cavalry. It is only in this order that infantry can make use of its fire. If battalions consist of 800 men they will, in a formation of two ranks, be too much extended for most Chiefs of Battalions. Two companies of each battalion ought then to be formed as columns of reserve. The order in two ranks is beyond question best suited, in oblique attacks, for that part of the line not to be engaged; and with rifle-muskets now used the two-rank formation will be found better for that part of the line which is, to strike also. Even with old muskets the two-rank formation was used by the British very successfully at Waterloo in squares against cavalry. The fire in two-rank formation is made with more order, more easily, and is better aimed. The march in line of battle ought to be employed whenever the ground permits it, within 1000 yards of the enemy. We lose then fewer men by cannon; and even if it be desirable to approach the enemy in column (which is very rare, and should even then be in columns of single battalions), the march ought still to be in line of battle until within two hundred yards, and then the column of attack ought to be formed while marching. Troops cannot be too much exercised in marching in line of battle. This march is no more difficult than the march of many heads of columns upon the same line, perhaps even less so, for it is difficult to maintain between the columns the intervals necessary for deployments.

Changes of front very near the enemy are rarely perpendicular. The new front nearly always forms with the line of battle an acute angle. In this case it is necessary to guard against breaking the battalions into column. It is better to use the changes of direction for the line of battle prescribed by the tactics. The two pivot battalions may be thrown upon the new line by companies half-faced to the right or left. The other battalions ought to be directed upon the new line by changes of direction which would least expose them to artillery. If, however, we have to guard against cavalry during the execution of the movement, it will be better to break into column the battalions of the leading wing. They will thus form the stem of the battery, and would rapidly make good dispositions against cavalry, as they would only be obliged to close in mass upon the Grenadiers and form square. Changes of front forward are possible under fire, but changes of front to the rear are not so. I believe, says Marshal Bugeaud, that the loss of one of our battles in Spain may, in great part, be attributed to a change of front in rear of the left wing, which was attempted at a moment when warmly engaged. The movement rapidly degenerated into a rout; and it could not be otherwise. There are no troops with sufficient *sang-froid* and self-possession to make that movement under the fire of ball and grape. To make the movement it is necessary first to stop the enemy, and the means of doing that vary with circumstances and the resources within our command. Charges of cavalry—above all if they threaten the flanks of the enemy's line—would cover the change of front to the rear. If cavalry be not at hand, there is no better means than to advance the second line to the position that it is desired that the front should occupy after its change of front, and withdraw the first line at a run, directing it to form the second line, passing through the intervals of the battalions, now become the first line. If a line is about coming up with the enemy at the moment of receiving the order to change front, it would be better to finish the charge, by putting the first line of the enemy in rout before executing the movement to the rear. This last principle is applicable to retreats generally: it is often necessary to overthrow an enemy who is too nigh before retiring. Running movements may, in many cases, save us from destruction. It is necessary, then, to exercise troops in such movements, and make them run in disorder, and re-form at some given point.

The *order in echelons* is the maneuver of oblique attacks. By that means we approximate those troops only who are to fight. The remainder are at once threatening and defensive. They hold in check one or many parts of the order of battle of the enemy, and present the best possible protection to the attacking portion. Some echelons to the right and left of that which attacks are greatly better than any other support. They render, if not impossible, at least very difficult an attack upon the flank of the attacking portion, as that cannot be assailed without the enemy in turn being taken in flank by echelons. And the latter cannot be turned except by strong movements, which must weaken the army executing them, and also afford necessary time to guard against them. Instead of placing flank brigades in advance of the front of the columns or lines that they protect, it is better to place them in rear. Besides the physical advantages of this disposition, there are moral advantages, inasmuch as the latter position enables the echelons to assail, whereas if they were immediately on the flank of the attack they might be assailed. In theory, echelons are placed at regular distances. In practice, the distance is determined by circumstances, and above all by the formation of the ground. The regularity of echelons can, therefore, only exist in broad plains. The greater or less distance between echelons depends upon the number of troops, the distances between those of the enemy, and the ulterior views of the General-in-Chief; but in general they ought to be within mutual succor, and if cavalry is to be repulsed, they ought to cross fire at about 150 paces after having formed square. The different movements of echelons, the changes of front in each echelon, with the same angle, are very useful in war; it is necessary, therefore, that troops should be exercised in such movements. See *Maneuvers*.

EXARCH.—The title first conferred by Justinian on his Commander-in Chief and the Vicegerent in Italy. The conquest of Italy by the Goths in the early part of the sixth century was a severe blow to the Byzantine pride; and Justinian determined to wipe out the disgrace and recover the imperial territories. The execution of this project was intrusted at first to Belisarius, and afterwards to Narses, by whom the reconquest of Italy was effected. The latter was the first who bore the title of Exarch; and the district over which he ruled was called the *Exarchate*. The seat of the Exarchs was Ravenna, the different towns and territories belonging to them being governed by subordinate rulers, styled *Duces* or Dukes. The extent of the Exarchate, however, was by degrees diminished, until it embraced only the country about Ravenna, the present Romagna, and the coasts of Rimini as far as Ancona. This was brought about partly by the conquests of the Longobards, partly by the Dukes of Venice and Naples making themselves independent. In the year 728 even this small portion fell, for a short time, into the hands of the Longobards. In 752 Astulf, or Astolphus, King of the Longobards, put an end to the Byzantine rule at Ravenna; but in 755 he was compelled to resign the Exarchate to Pepin the Less, King of the Franks, who gave it over to the Bishop of Rome, Stephanus II.—In the Christian Church Exarch was originally a title of the Bishops, afterward of a Bishop who presided over several others—a Primate. It was borne by the Bishops of Alexandria, Antioch, Ephesus, Cæsarea, and Constantinople, till it was finally exchanged for the title of Patriarch. A Superior over several monasteries was also called in ancient times an Exarch. The same title is also borne, in the modern Greek Church, by the person who "visits" officially, as a sort of Legate of the Patriarch, the clergy and churches in a Province.

EXAUCTORATIO.—In the Roman military discipline, this differed from the *missio*, which was a full discharge, and occurred after soldiers had served in the army 20 years; whereas the *exauctoratio* was only a partial discharge; they lost their pay, indeed, but still kept under their covers or vexilla, though not under the aquilla or eagle, which was the standard of the Legion; whence, instead of *Legionarii*, they were called *Subsignarii*, and were retained until they had either served their full time or had lands assigned them. The exauctoratio took place after they had served 17 years.



(End Elevation.)

Land-excavator used by Panama Canal Company.

(Side Elevation.)

EXCAVATOR.—A machine for digging earth and removing the same from holes. It is usually mounted on a carriage which traverses on a temporary track. At one end of the frame is a crane, which has a circular adjustment on its axial post. To the end of the chain-tackle is suspended a scoop made of boiler iron, whose lip is a steel edge with fingers. Direction is given to the scoop by means of a beam which may be called the scoop-handle, and when the scoop has been thrust by its weight into the earth, the beam affords a fulcrum on which the scoop rotates when the tackle-chain is wound up on the drum by the action of the steam-engine. The excavated earth along some parts of the line of the Suez Canal was transported by means of a pump. By the aid of a steam-pump water was mixed with the earth brought up by the dredge, and the mud so formed was spouted out upon both banks of the canal to such distance and in such quantities as to form high compact ramparts against the sand-showers blowing in from the desert. Ninety-six million cubic yards of earth have been thus taken out. The accompanying detailed drawings show the side and end elevations of a land-excavator such as is used by the Panama Canal Company, now engaged in carrying out M. de Lesseps' bold undertaking of constructing a canal across the Isthmus of Panama. This machine is built by the Osgood Dredge Company, Albany, N. Y., and is destined not only to revolutionize the past systems of excavating, but in consequence of its adaptability and effectiveness will play an important part in the construction of field and hasty fortifications. An examination of the drawing will show that the superiority of the design lies in the admirable distribution of the working strains, by which most of them are sent directly to the ground through the A-frame and jack-screws; in the placing of a spring in the boom-chain, thereby diminishing the shocks which would otherwise pass unimpeded to the A-frame, thus prolonging the life of the machine. The A-frame and boom are hinged, and can be lowered by steam-power on a platform-car, in front of the excavator; the machinery being mounted on a car of standard gauge, the excavator can then be put in any freight-train. The machines can also be used as wrecking or derrick cars. They are self-propelling. The dippers are made of *plate-steel* with *solid steel teeth* reaching nearly to the bottom of the dipper. The teeth are bolted on, and can readily be removed in order to have them sharpened. The sheave-shafts, stay-rod pins, etc., are of *steel.* The booms and A-frames are made of angle-iron, strongly braced, stayed, and riveted together. By means of the boom-chain, the boom can be adjusted to high or low lifts. A light iron framework with corrugated iron roof, or a wooden house, as may be preferred, shelters the engineer and fireman. Attached to the car is an iron tank for supplying the boiler with water. This is placed under the car and contains about 550 gallons. The fact that the machinery is mounted on a car having spring trucks is of great advantage to the life of the machine. These trucks give great elasticity and offer a favorable contrast to the rigidity of many of the ordinary steam-shovels. Again, the fact that the car has *eight* wheels gives to the machine a much larger bearing surface and gives less trouble in settling on the track, while it is at work, than does the ordinary steam-shovel. This point will be appreciated as one of great importance by any one who has had experience in the practical working of excavators. This is considered the best way to mount an excavator. In operation the weight is taken off the forward trucks by means of the jack-screws. Each jack-screw is supplied with a ratchet-wrench. The hoisting, the swinging, and the working of the dipper-handle are all accomplished through the agency of friction. There is no rack-and-pinion arrangement. The manner of construction—entirely different from that of the ordinary crane-machine—permits the use of a much larger power than could be put in a crane-excavator. The boom arrangement permits digging farther in advance of the machine than is possible with the crane-excavator. While this machine can make moves ahead of eight feet, the move ahead of the ordinary steam-shovel is only four feet. This excavator thus saves one half of the time occupied in moving. The speed of the machine in sand or gravel is three dippers per minute. In *hard material* it has a great superiority over crane-excavators, because of the great power and its being much more efficiently applied. For use in hard-pan the dipper is especially designed. The excavator has two independent pairs of engines. The main engines are for pulling the dipper through the bank and for swinging the turntable, which latter is accomplished by means of the independent friction-drums. On the turn-table is a pair of coupled engines which revolve with the turntable. They operate a drum around which winds a chain and, the chain being properly attached to the dipper-handle, run the handle out and in with great rapidity and ease. They hold the dipper to its work while the main engines are pulling it through the bank. These engines are supplied with steam through a universal joint, thus doing away with *flexible pipes*, which are liable to burst, to cause delay, and to scald the cranesman. The boilers are upright ones, of sufficient capacity for the work to be performed, and are made so that the cones and stacks can be taken off to enable the excavator to go under bridges. See *Dredging-machine.*

EXCHANGE OF PRISONERS.—Exchanges of prisoners take place, number for number, rank for rank, wounded for wounded, with added condition for added condition, such, for instance, as not to serve for a certain period.

In exchanging prisoners of war, such numbers of persons of inferior rank may be substituted as an equivalent for one of superior rank as may be agreed upon by cartel, which requires either the sanction of the Government or of the Commander of the Army in the field.

A prisoner of war is in honor bound truly to state to the captor his rank; and he is not to assume a lower rank than belongs to him in order to cause a more advantageous exchange, nor a higher rank for the purpose of obtaining better treatment. Offenses to the contrary have been justly punished by the Commanders of released prisoners, and may be good cause for refusing to release such prisoners.

The surplus number of prisoners of war remaining after an exchange has taken place is sometimes released either for the payment of a stipulated sum of money, or, in urgent cases, of provisions, clothing, or other necessaries. Such arrangement, however, requires the sanction of the highest authority.

The exchange of prisoners of war is an act of convenience to both belligerents. If no general cartel has been concluded, it cannot be demanded by either of them. No belligerent is obliged to exchange prisoners of war.

No exchange of prisoners should be made except after complete capture, and after an accurate account of them and a list of the captured officers has been taken. See *Cartel*, *Parole*, and *Prisoners of War.*

EXCHANGES.—Certain arrangements made between officers of the English army. An officer may exchange, or change places, in the Guards or Line, with another of equal rank in any regiment of the above Corps by mutual consent, and subject to the approval of the Minister of War, and on payment of a sum agreed upon between the officers. On the abolition of the system of purchasing commissions in 1871, the sum paid in effecting an exchange was limited to the actual cost thrown upon the officer exchanging. In view, however, of the general wish of the army, a bill was introduced into Parliament in 1874 (but was withdrawn as regards that session) to render again legal the payment of money as a bonus for exchanges. In the following year (1875) the bill, having been again brought forward, was passed. As each of the exchanging officers enters his new Corps at the bottom of his rank, exchange benefits officers who stick to their regiment by advancing them towards the top of the list, and therefore nearer to promotion. An officer on full pay may exchange with another on half pay, provided a younger life be not thereby added to the half-pay list, and subject always to the consent of the Secretary for War. Exchanges are ordinarily arranged by the Army Agents. See *Transfer.*

EXCUBIÆ.—In ancient warfare, the watches and guards kept in the day by the Roman soldiers. They differed from the *vigiliæ*, which were always kept in the night.

EXECUTION.—Military execution is the pillaging or plundering of a country by the enemy's army. It also means every kind of punishment inflicted in the army by the sentence of a Court-Martial, which is of various kinds, including putting a soldier to death by shooting him, which is the ordinary punishment of deserters to the enemy, mutineers, etc. This form of death is considered less disgraceful than hanging by the neck. In some rare instances blowing from the mouth of a gun has been resorted to.

EXECUTION OF LAWS.—On all occasions when the troops are employed in restoring or maintaining public order among their fellow-citizens, the use of arms, and particularly fire-arms, is obviously attended with loss of life or limb to private individuals; and for these consequences a military man may be called to stand at the bar of a Criminal Court. A private soldier also may occasionally be detached on special duty, with the necessity of exercising discretion as to the use of his arms; and in such cases he is responsible, like an officer, for the right use or exercise of such discretion. One of the earliest reported cases on this subject occurred in 1735, when Thomas Macadam, a Private Sentinel, and James Long, a Corporal, were tried before the Admiralty Court of Scotland, upon a charge of murder under the following circumstances: They were ordered to attend some customhouse officers, for their protection in making a legal seizure; and being in a boat with the officers in quest of the contraband goods, one Frazer and his companions came up with them, leaped into the boat, and endeavored to disarm the soldiers. In the scuffle the prisoners stabbed Frazer with their bayonets, and threw him into the sea. For this homicide the prisoners were tried and convicted of murder by a jury; and the Judge Admiral sentenced them to death.

But the High Court of Justiciary reversed this judgment, on the ground that the homicide in question was necessary for securing the execution of the trust committed to the prisoners. The report of this case contains the following remarks upon it by Mr. Forbes, afterwards Lord President of the Court of Session of Scotland; and they appear to be of great importance to military men: "Where a man has *by law* weapons put into his hands, to be employed not only in defense of his life when attacked, but in support of the execution of the laws, and in defense of the property of the Crown, and the liberty of any subject, he doubtless may use those weapons, not only when his own life is put so far in danger that he cannot probably escape without making use of them, but also when there is imminent danger that he may by violence be disabled to execute his trust, without resorting to the use of those weapons; but when the life of the officer is exposed to no danger, when his duty does not necessarily call upon him for the execution of his trust, or for the preservation of the property of the Crown, or the preservation of the property or liberty of the subject, to make use of mortal weapons, which may destroy His Majesty's subjects, especially numbers of them who may be innocent, it is impossible from the resolution of the Court of Justiciary to expect any countenance to, or shelter for, the inhuman act." This quotation, in the latter part of it, has a direct bearing on the case of the unfortunate Captain Porteus, whose trial took place in the following year, and whose melancholy fate is the groundwork of Sir Walter Scott's *Heart of Mid-Lothian.* In the year 1736 the Collector of Customs on the coast of Fife made a seizure of contraband goods of considerable value, which were condemned and sold. Two of the proprietors of these goods took an opportunity of robbing the Collector of just so much money as these goods had sold for. They regarded this as merely a fair reprisal and no robbery; but they were nevertheless taken up, tried, and condemned to death for the fact. With the exception of some smuggling transactions, in which they had been concerned, the prisoners were men of fair character; and the mob expressed much dissatisfaction with their sentence and the prospect of their execution. On the Sunday preceding the day appointed for the execution, the prisoners were taken to a church near the jail, attended by only three or four of the City Guards, to hear divine service. None of the congregation had assembled, and the guards being feeble old men, one of the prisoners made a spring over the pew where they sat, while the other, whose name was Wilson, in order to facilitate his companion's escape, caught hold of two of the guards with his hands, and seized another with his teeth, and thus enabled his companion to join the mob outside, who bore him off to a place of safety. Wilson then composedly resumed his own seat, without making any attempt to recover his own liberty. This generous conduct of Wilson created a strong public feeling in his favor; and the Magistrates of Edinburgh soon learned that an attempt would be made by the mob to rescue him at the place of execution. They therefore procured some of the regular forces on duty in the suburbs to be posted at a convenient distance from the spot, so as to support the City Guard, in case they should be vigorously attacked. The officer whose turn it was to do duty as Captain of the City Guard being deemed unfit for the critical duties of the day, Captain Porteus, unfortunately for himself, was appointed to the command on the occasion. His men were served with ball-cartridge; and, by order of the Magistrates, they loaded their pieces when they went upon duty. The execution took place without any disturbance until the time arrived for cutting down the body, when the mob severely pelted the executioner with stones, which hit the guards as they surrounded the scaffold, and provoked them to fire upon the crowd. Some persons at a distance from the place of execution were thus killed. As soon as the body was removed, Captain Porteus withdrew his men, and marched up the West Bow, which is a narrow winding passage. The mob, having recovered from the fright occasioned by the previous firing, followed the guard up this passage, and pelted the rear with stones, which the guards returned with some dropping shot, whereby some were killed and others wounded. On reaching the guard-house they deposited their arms in the usual form, and Captain Porteus went with his piece in his hand to the Spread Eagle Tavern, where the Magistrates were assembled. On his arrival there, he was charged with the murder of the persons who had been slain by the City Guards, on the allegation that he had commanded the guards to fire. The mob was very riotous, and called for justice upon him; and the Magistrates, after adjourning to the Council Chamber, committed him to the Tolbooth for trial. The strongest feeling existed against him on the part of the mob, until the hour of his trial before the High Court of Justiciary arrived, when, to their great satisfaction, he was found guilty, and condemned to be hanged. The higher classes of society, however, unaffected by the popular prejudice against the unfortunate prisoner, exerted themselves strenuously in his behalf, and succeeded in obtaining a reprieve. This created the greatest discontent among the lower orders, who, on the night before the day originally appointed for the execution, broke open the jail, dragged the unhappy Captain Porteus downstairs by the heels, carried him to the common place of execution, and there, throwing a rope over a dyer's pole, executed him with many marks of barbarity. The perpetrators of this outrage were never discovered, and the subject gave rise to very warm debates in Parliament, particularly in the House of Lords, with respect to the conduct of the City Magistrates and Officers. It was quite clear, however, with reference to the criminality of Captain Porteus, that he had ordered his men to fire without sufficient cause or justification; and, under such circumstances, he was in point of the law justly found guilty of murder.

Ensign Hugh Maxwell, of the Lanarkshire Militia, was tried in 1807, before the High Court of Justiciary of Scotland, for the murder of Charles Cottier, a French prisoner of war at Greenlaw, by improperly ordering John Gow, a Private Sentinel, to fire into the room where Cottier and other prisoners were confined, and so causing him to be mortally wounded. It appeared that Ensign Maxwell had been appointed to the military guard over 300 prisoners of war, chiefly taken from French privateers. The building in which they were confined was of no great strength, and afforded some possibilities of escape. The prisoners were of a very turbulent character, and to prevent their escape during the long winter nights an order was given that all lights in the prison should be put out by nine o'clock, and that if this was not done at the second call the guard were to fire upon the prisoners, who were often warned that this would be the consequence of disobedience with regard to the lights. On the night in question there was a tumult in the prison, but of no great importance; and Ensign Maxwell's attention having been on that account drawn to the prisoners, he observed a light burning beyond the appointed hour, and twice ordered it to be put out. This order not being obeyed, he ordered the sentry to fire, but the musket merely snapped. He repeated the order; the sentinel fired again, and Cottier received his mortal wound. At this time there was no symptom of disorder in the prison, and the prisoners were all in bed. The general instructions issued from the Adjutant General's Office in Edinburgh, for the conduct of the troops guarding the prison, contained no such order as that which Ensign Maxwell had acted upon; and it appeared that the order in question was a mere verbal one, which had from time to time, in the hearing of the officers, been repeated by the Corporal to the sentries, on mounting guard, and had never been countermanded by those officers, who were also senior to Ensign Maxwell. The Lord Justice Clerk described the case to the jury as altogether the most distressing that any Court had ever been called upon to consider, and laid it down most distinctly that Ensign Maxwell could only defend himself by proving specific orders, which he was bound to obey without discretion; or by showing that in the general discharge of his duty he was placed in circumstances which gave him discretion and called upon him to do what he did. His Lordship was of opinion that both these grounds of defense failed in the present case; and the jury having found Ensign Maxwell guilty of the minor offense of *culpable homicide*, with a recommendation to mercy, the Court sentenced him to nine months' imprisonment. Ensign Maxwell's conduct certainly exhibited none of those gross features which characterize murder; but at the same time he was guilty of a rash and inconsiderate act, which, if he had not been engaged at the time in military duty, though he was mistaken in the exercise of it, would probably have been held to amount to murder. In Maxwell's case, the soldier who fired the shot was not prosecuted for the act, nor was he liable to such prosecution.

It is laid down that if a ship's sentinel shoot a man because he persists in approaching the ship when he has been ordered not to do so, it will be murder, unless such an act was necessary for the ship's safety. And it will be murder, though the sentinel had orders to prevent the approach of any boats, had ammunition given to him when he was put on guard, and acted on the mistaken impression that it was his duty. In Rex *v.* Thomas, the prisoner was sentinel on board H.M.S. *Achille* when she was paying off. The orders to him from the preceding sentinel were to keep off all boats, unless they had officers in uniform in them, or unless the officer on deck allowed them to approach; and he received a musket, three blank cartridges, and three balls. The boats pressed, upon which he repeatedly called to them to keep off; but one of them persisted, and came close under the ship, and he then fired at a man in the boat and killed him. It was put to the jury to find whether the sentinel did not fire under the mistaken impression that it was his duty; and they found that he did. But the case being reserved for the opinion of the Judges, their Lordships were unanimous that it was murder. They thought it, however, a proper case for a pardon; and further, they were of opinion that if the act had been necessary for the preservation of the ship, as if the deceased had been mutinous, the sentinel would have been justified.

The several cases already cited turned upon the improper exercise of discretion by the officers concerned. But in the following case, though not attended with actual consequences involving a criminal charge, the discretion in the use of arms was wisely exercised, and indicated great presence of mind and correctness of judgment. Some years ago the public journals of London recorded the meritorious behavior of a Private Sentry, upon the occasion of a riotous mob assembled at the entrance of Downing Street, with the intention of attacking the Government Offices in that quarter of the town. This man standing alone presented his musket, and threatened to fire upon the crowd if the slightest attempt were made to approach the particular office for the defense of which he was placed on duty, and succeeded by the terror thus created, though at a great risk of consequences to himself, in keeping the rioters at bay until a larger force arrived to assist him. The soldier's conduct was publicly much approved. It was also clearly legal according to Macadam's case; and if after the announcement of his intentions the mob had pressed forward to execute their purpose, he would have been held justified at law in firing at the rioters upon his own responsibility. The Duke of Wellington, as Constable of the Tower, testified his marked approbation of this man's conduct, by promoting him at once to a Wardership at that fortress. During the Irish insurrection of 1848 Smith O'Brien was arrested at the railway station of Thurles, on a charge of high treason. A public passenger-train was on the point of starting for Dublin, and the engineer was mounted on the engine, with the steam up, and everything in readiness for the immediate prosecution of the journey. The scene of the arrest lay in the disturbed district, which was in the occupation of the troops employed to suppress the insurrection and prevent its extension. General Macdonald's Aide-de-Camp, having been apprised of the arrest, proceeded instantly to the station, and there commanded the engineer to dismount from the engine and to stop the train; it being of the utmost importance to the public safety and service that the news of the arrest should not be carried along the line of railway, as the country people might assemble in great numbers and destroy the rails, and rescue the prisoner, or otherwise impede the conveyance of the prisoner to Dublin. Such interference would obviously have occasioned great loss of life, besides the danger to the public service at such a season. The engineer at first refused to obey the Aide-de-Camp's orders, whereupon the officer presented his pistol at the engineer, and threatened him with instant death if he persisted in his refusal. The man then dismounted; but it is conceived that the officer pursued a correct line of conduct, and exercised upon the occasion a sound discretion, which would have been a good legal defense to him if he had ultimately proceeded to execute his threat upon the engineer. "Power in law" (says Sir Edward Coke) "means power with force." The right of officers or soldiers to interfere in quelling *a felonious riot*, whether with or without superior military orders, or the direction of a Civil Magistrate, is quite clear and beyond the possibility of mistake. This subject, however, was formerly little understood; and military men failed in their public duty through excess of caution.

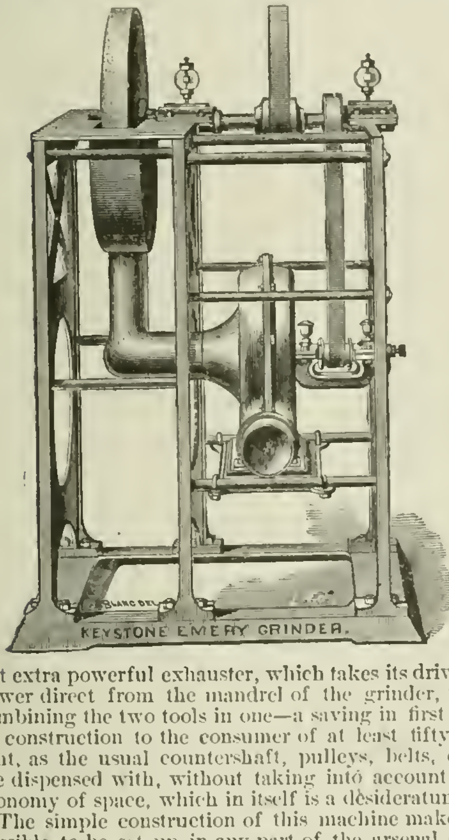
George III. and his Attorney General (Wedderburn) both deservedly acquired high credit for their energy in the crisis of the riots of 1780. When the King heard that the troops which had been marched in from all quarters were of no avail in restoring order, on account of a scruple that they could not be ordered to fire till an hour after the Riot Act had been read, he called a Cabinet Council, at which he himself presided, and propounded for their consideration the legality of this opinion. There was much hesitation among the Councilors, as they remembered the outcry that had been made by reason of some deaths from the interference of the military in Wilke's riots, and the eagerness with which Grand-juries had found indictments for murder against those who had acted under the command of their superiors. At last the question was put to the Attorney General, who attended as Assessor, and he gave a clear, unhesitating, and unqualified answer to the effect, that if the mob were committing a felony, as by burning down dwelling-houses, and could not be prevented from doing so by other means, the military, according to the law of England, might and ought to be ordered to fire upon them; the reading of the Riot Act being wholly unnecessary and nugatory under such circumstances. The exact words used by him on this occasion are not known; but they must have been nearly the same which he employed when he shortly afterwards expounded from the judgment-seat the true doctrine upon the subject. The requisite orders were issued to the troops, the conflagrations were stopped, and tranquillity was speedily restored. This eminent lawyer having become Chief Justice of the Court of Common Pleas, with the title of Lord Loughborough, delivered a charge to the Grand-jury on the special commission for the trial of the rioters of 1780, in the following terms: "I take this public opportunity of mentioning a fatal mistake into which many persons have fallen. It has been imagined, because the law allows an hour for the dispersion of a mob to whom the Riot Act has been read by the Magistrate, the better to support the civil authority, that during that time the civil power and the Magistracy are disarmed, and the King's subjects, whose duty it is at all times to suppress riots, are to remain quiet and passive. No such meaning was within view of the Legislature, nor does the operation of the Act warrant such effect. The Civil Magistrates are left in possession of all those powers which the law had given them before. If the mob collectively, or a part of it, or any individual within or before the expiration of that hour, attempts, or begins to perpetrate, an outrage amounting to felony, to pull down a house, or by any other act to violate the law, it is the duty of *all present*, of whatever description they may be, to endeavor to stop the mischief, and to apprehend the offender." "A riot" (says Mr. Justice Gaselee) "is not the less a riot, nor an illegal meeting, because the proclamation of the Riot Act has not been read; the effect of that proclamation being to make the parties guilty of a capital offense if they do not disperse within an hour; but if that proclamation be not read, the common-law offense remains, and it is a misdemeanor; and all Magistrates, Constables, and even private individuals are justified in dispersing the offenders; and if they cannot otherwise succeed in doing so, they may use force." After the suppression of the great riots of London in 1780 by the aid of the troops, as already mentioned, the Government was acrimoniously attacked both in and out of Parliament, on the ground that the employment of a military force, to quell riots by firing on the people, could only be justified, if at all, by martial law proclaimed under a special exercise of the royal prerogative; and it was thence argued that the nation was living under martial law. But Lord Mansfield, the Chief Justice of the King's Bench, addressed the House of Lords on this subject, and placed it in its true light. "I hold" (said his Lordship) "that His Majesty, in the orders he issued by the advice of his Ministers, acted perfectly and strictly according to the common law of the land and the principles of the Constitution. . . . . Every individual in his private capacity may lawfully interfere to suppress a riot, much more to prevent acts of felony, treason, and rebellion. Not only is he authorized to interfere for such a purpose, but it is his duty to do so; and if called upon by a Magistrate, he is punishable in case of refusal. What any single individual may lawfully do for the prevention of crime and preservation of the public peace may be done by any number assembled to perform their duty as good citizens. It is the peculiar business of all Constables to apprehend rioters, to endeavor to disperse all unlawful assemblies, and, in case of resistance, to attack, wound, nay, kill those who continue to resist; taking care not to commit unnecessary violence, or to abuse the power legally vested in them. Every one is justified in doing what is necessary for the faithful discharge of the duties annexed to his office, although he is doubly culpable if he wantonly commits an illegal act under the color or pretext of law. The persons who assisted in the suppression of those tumults are to be considered mere private individuals acting as duty required. My Lords, we have not been living under martial law, but under that law which it has long been my sacred function to administer. For any violation of that law the offenders are amenable to our ordinary Courts of Justice, and may be tried before a jury of their countrymen. Supposing a soldier or any other military person who acted in the course of the late riots had exceeded the power with which he was invested, I have not a single doubt that he may be punished, not by a Court-Martial, but upon an indictment to be found by the Grand Inquest of the City of London or the County of Middlesex, and disposed of before the ermined Judges sitting in Justice Hall at the Old Bailey. Consequently the idea is false that we are living under a military government, or that, since the commencement of the riots, any part of the laws or of the Constitution has been suspended or dispensed with. I believe that much mischief has arisen from a misconception of the Riot Act, which enacts that after proclamation made persons present at a riotous assembly shall depart to their homes; those who remain there above an hour afterwards shall be guilty of felony and liable to suffer death. From this it has been imagined that the military cannot act, whatever crimes may be committed in their sight, till an hour after such proclamation has been made, or, as it is termed, 'the Riot Act is read.' But the Riot Act only introduces a new offense—remaining an hour after the proclamation—without qualifying any pre-existing law, or abridging the means which before existed for preventing or punishing crimes."

It may, perhaps, be useful to subjoin a General Order issued to the Commander-in-Chief at Madras, in April, 1825, during the government of Sir Thomas Munro, shortly after a melancholy affair at Kittoor, in which one or two civil servants of the East India Company lost their lives under circumstances which, in the opinion of the public authorities, indicated, both in the civil and military functionaries, a want of general knowledge respecting the subject of the order: "The Honorable the Governor in Council deems it necessary to lay down the following rules relative to the exercise of the authority with which Civil Magistrates, and other officers acting in a similar capacity, are vested, for calling out military force to preserve the peace of the country: 1. The first and most important rule is, that no Civil Officer shall call out troops until he is convinced, by mature consideration of all the circumstances, that such a measure is necessary. 2. When the Civil Officer is satisfied of the necessity of the measure, he should, before carrying it into execution, receive the sanction of Government, unless the delay requisite for that purpose is likely to prove detrimental to the public interests. In that case, also, he should fully report the circumstances to Government. 3. When the Civil Officer may not deem it safe to wait for the orders of Government, he should address his requisition for troops, not to any subordinate military officer, but to the officer commanding the division, to whom he should communicate his object in making it, and all the information he may possess regarding the strength and designs of those by whom the public peace is menaced or disturbed. His duty is confined to these points. *He has no authority in directing military operations.* 4. The officer commanding the troops has alone authority to determine the number and nature of those to be employed, the time and manner of making the attack, and every other operation for the reduction of the enemy. 5. Whenever the officer commanding the division may think the troops at his disposal inadequate to the enterprise, he should call upon the officer commanding the neighboring division for aid, and report to Government and to the Commander-in-Chief. 6. No Assistant or Subordinate Magistrate is authorized to call out troops. When any such officer thinks military aid necessary, he must refer to his Superior, the Principal Magistrate of the district. The foregoing rules are to be observed when it can be done without danger to the public safety. Should any extraordinary case occur, which admits of no delay, civil and military officers must then act according to the emergency and the best of their judgment. Such cases, however, can rarely occur, unless when an enemy becomes the assailant; and therefore occasion can hardly ever arise for departing from the regular course of calling out troops, only by the requisition of the principal Civil Magistrates of the Province, to the officer commanding the division. Ordered, that the foregoing resolutions be published in General Orders to the army, and be communicated for the information and guidance of such Civil Officers as they concern." See *Posse Comitatus*.

EXEMPT.—A term variously applied in military matters. Men of certain age are exempt from serving in the militia. An Aide-de-Camp and Brigade Major are exempt from all regimental duties while serving in those capacities. Officers on Courts-Martial are sometimes exempt from all other duties until the Courts are dissolved.

EXERCISE.—Maneuvering bodies of men together. The drill of a mounted battery of artillery is termed *exercise*. All such use as the soldier is instructed in in the knowledge of his weapon is termed *exercise*, such as bayonet-exercise, firing-exercise, lance-exercise, manual, pistol, and sword exercise. See *Gymnastics*.

EXHAUSTER.—An apparatus used in connection with the emery-grinder and similar machines to carry off the emery-dust, shavings, etc. The value of this excellent machine is highly appreciated by those who have much work to perform at the emery-wheel. Emery-dust set free in a workshop is an intolerable nuisance, and destructive to fine machinery, even though this be situated in an adjoining room. It has caused serious inconvenience to the eyes as well as fatal injury to the lungs of the operator. In consequence these valuable, and now almost indispensable, assistants to the iron-worker are rejected by many who, if it were not so, would be glad to introduce them at once. To the grinder is attached a small



KEYSTONE EMERY GRINDER.

but extra powerful exhauster, which takes its driving-power direct from the mandrel of the grinder, thus combining the two tools in one—a saving in first cost of construction to the consumer of at least fifty per cent, as the usual countershaft, pulleys, belts, etc., are dispensed with, without taking into account the economy of space, which in itself is a desideratum.

The simple construction of this machine makes it possible to be set up in any part of the arsenal convenient to the driving-power. The refuse dust may be deposited into a small tank of water immediately in front of the table, or it may be conveyed out of the building, either at a window or through an ordinary chimney-flue. As every particle of dust is carried from the stone as fast as made, the eyes and respiratory organs of the workman will need no artificial protection. See *Emery-grinder*.

EXON.—In England, an officer of the Yeomen of the Royal Guard; an exempt.

EXOSTRE.—The bridge of the *helepole*, or movable tower of the ancients, by which they passed upon a wall during a siege.

EXPANDING PROJECTILES.—Projectiles of this class are forced to take the grooves by the action of the charge of powder, and require no other precaution in loading than spherical shell. It is essential, however, that the base-ring of every rifle-projectile, especially the Parrott, shall be greased before entering it into the gun, to prevent the formation of a hard deposit in the grooves. Parrott's projectile is composed of a cast-iron body and brass ring cast into a rabbet formed around its base. The ring is from 1 inch to 1¼ inch in width, and about 1 inch in maximum depth. The gas presses against the bottom of the ring and underneath it, so as to expand it into the grooves of the gun. To prevent the ring from turning in the rabbet, the latter is recessed at several points of its circumference, like the teeth of gearing. The diameter of the rabbet is greatest at the extreme rear of the shot, so that the brass ring cannot fly off without breaking. The entire projectile is slightly smaller than the bore, so as to be easily rammed home. The projectile has a slight groove turned out of the iron of the base to permit the powder gases to enter and expand the ring. The use of a little grease or other lubricating material on the base of the projectile, before firing, is advantageous. Parrott's shot for iron-clad fighting, as shown in the drawing, is entirely of cast-iron, but is reduced and chilled at the end, which prevents its mashing like strong soft cast-iron.

The new Parrott projectile differs from that just described in that the base is separated from the expanding ring by a *cannelure* which renders its taking the grooves more certain. Those for the 60-pounder and under have one hole for the core-stem, which becomes the fuse-hole. The larger projectiles have a hole in each end in consequence of the necessity of using two core-stems to steady the core. The battering-shell have but one hole in rear which serves as a loading-hole; the hole in rear is closed by a screw-plug. The Hotchkiss projectile is composed of three parts: the body, the expanding ring of lead, and the cast-iron cup. The action of the charge is to crowd the cup against the soft-metal ring, thereby expanding it into the rifling of the gun. The time-fuse projectile has deep longitudinal grooves cut on its sides to allow the flame to pass over and ignite the fuse. The last rifle-projectile submitted by Mr. Hotchkiss has an expanding cup of brass attached to its base in a very peculiar manner. The cup is divided into four parts by thin projections on the base of the projectile. This arrangement is intended to facilitate the expansion of the cup and to allow the flame to pass over to ignite the fuse.

The Butler shell also belongs to this class, and differs from the mode of attaching the expanding ring and in the position of the cannelure. The expanding ring is screwed on to the base, in such a manner that the rotary motion screws in tighter; the rear part is divided by the cannelure into two lips, so that the gases are distributed evenly and the entrance of the gas between the ring and the body of the projectile is prevented; the grip of the inner lip on the projectile being also increased by the wedging action of the gas. See *Arrick Projectile, Blakely Projectile, Butler Projectiles, Confederate Projectiles, Dana Projectile, Dyer Projectile, Hotchkiss Projectiles, James Projectile, Parrott Projectiles, Projectiles, Sawyer Projectiles*, and *Schenkle Projectile*.

EXPANSIVE SYSTEM OF RIFLING.—This system embraces all projectiles which in loading are inserted in the gun without respect to the rifling, but which take the grooves by the action of the gases of discharge upon a device or feature of the projectile, which is readily expanded thereby into the grooves of the gun. This class of projectiles has been so extensively and almost exclusively used in the United States that it is known as the American system. The chief projectiles of this class are: 1. Those where the sabot is of lead or soft metal. In these the windage is apt to be entirely closed. The lead may strip or be forced over the projectile, and balloting or wedging be induced. 2. Those having sabots of copper or brass, cup-shaped on the bottom of the projectile. These seem to suffer from the violence of the explosion within the cup, which is apt to be broken or unevenly set up. 3. Those where a leaden jacket is forced out by the action of the discharge upon a wedge or key. These have small capacity as shell and little strength as shot, strip easily, and are open to many objections. 4. Those where a concave or convex disk is flattened against the base of the projectile, or in addition is provided with a flange or key which is driven by the discharge upon the tapered base of the projectile. 5. Those where the rotating device consists of an annular band or ring attached to the base of the projectile and intended to be expanded into the rifling by the gases of discharge. These have proved most successful in practice. See *System of Rifling.*

EXPATRIATION.—A voluntary transfer of residence and allegiance from one's native land to another country and government. Despotic governments have assumed the right to forbid such a change on the part of their citizens, but the United States recognizes the right of the individual citizen, at his own pleasure, to leave the country of his birth and make his home in a foreign land. Naturalization, however, is necessary to the complete transfer of allegiance. The United States defends the rights and liberties of naturalized precisely as it does those of native citizens. A naturalized citizen of this country, visiting his native land, is protected by the American flag as though he had been born on American soil. Of course this right of expatriation cannot be made a cover for a previous breach of trust, or the commission of any crime, in the place of one's birth; but the assumption that the law of his native land requiring him at a certain time of his life to do military duty nullifies for the time being a man's right of expatriation is not allowed by the United States. Thousands of young men leave the Old World for the avowed purpose of avoiding military conscription, and the United States welcomes them to citizenship, with all its rights and obligations.

EXPEDITION.—The organization and march of a small army or body of men for hostile purposes. One of the principles of many small expeditions is surprise, which, if well carried out, will insure success. To the soldier, no part of his duty is so exciting and interesting as an expedition, for it implies risk, hazard, and danger, in which nature of warfare the enthusiastic and daring soldier delights.

EXPENSE-MAGAZINES.—The very small gunpowder-magazines, containing the made-up ammunition for the service of the guns on the works, at the rate of so many rounds per gun. In fortifications of the old construction an expense-magazine was made in each bastion and battery, though this was not always the case. Expense-magazines are often made under the earthen ramparts of fortifications, with a passage cut into them in the interior slopes. In the more modern works, such as the *Instruction of Fortification at the Royal Military Academy, Woolwich*, it is shown that expense-magazines should be placed as near as is practicable to the guns which they have to supply, and may often be conveniently constructed under the traverses and below the level of the terre-plein, with lifts of communication. They can, if so situated, be easily secured against the enemy's fire, and be provided with subterranean communications with the main magazine, which would permit them to be replenished without risk, even during action. The first suggestions made as to the size of expense-magazines in fortifications of the present day gave four guns to be supplied by each, but a later recommendation proposes only two guns, in the case of very heavy guns.

EXPERIMENTS.—The trials or applications of any kind of military machines in order to ascertain their practical qualities and uses.

EXPIRATION OF SERVICE.—The termination of a soldier's contract of enlistment, usually five years.

EXPLOSION.—The term *explosion* is rather loosely used. Considering it as synonymous with explosive reaction, it may be defined as a chemical action causing the sudden or extremely rapid formation of a very great volume of highly expanded gas.

Explosive effect is caused by the blow or impulse given by this rapid production of gas in a confined space. The explosive character of the change, then, depends—1st. Upon the great change of state produced; that is, the formation of gas very much greater in volume than the substance from which it is derived, and which is still more expanded by the heat evolved. 2d. Upon the shortness of the time required for the change to take place. Both these causes operate to a greater or less extent in all explosive reactions. When both are fully exerted the most energetic chemical reaction, or, in other words, the most violent explosion, takes place. Also, the differences in explosions and explosive bodies depend upon the differing manner and proportions in which they are exerted. Thus, nitro-glycerine is much more powerful and violent than gunpowder, because it generates a larger volume of gas in a shorter time. Again, fulminating mercury is not more powerful than gunpowder, although the decomposition goes on more quickly, since the quantity of gas given off and the temperature of the reaction are less.

The kinds and quantity of gas given off in an explosive reaction depend upon the chemical composition of the explosive body and the character of the decomposition. The heat evolved during the reaction adds to the effect by increasing the tension (expanding the volume) of the gas formed. The heat given off in a reaction is an absolute quantity, the same whether the reaction goes on slowly or rapidly. But the *explosive* effect will evidently greatly depend upon the *rapidity* of the formation and expansion of the gas. Thus, if an explosive undergoes the same change under all circumstances of firing, then the total amount of force developed will always be the same; but the *explosive effect* will be increased as the time of action is lessened. Explosions are greatly affected by the circumstances attending them. Different substances, of course, give different results, from their different compositions and reactions. But we also find that the same substance will exercise a different explosive effect when fired under certain conditions than under others. These may affect either the rapidity or the results of the chemical change. By shortening the time of the reaction the explosion is rendered sharper and more violent. With some explosives the decomposition is different under different circumstances. Thus, gunpowder when fired under great pressure gives different products than when fired unconfined. Circumstances of explosion may be generally considered under—1st. Physical or mechanical condition of the explosive body itself. 2d. External conditions. 3d. Mode of firing. Many instances may be given indicating the influence of its state upon the explosion of a substance. Thus, nitro-glycerine at temperatures above 40° Fahr. is a liquid, and in a liquid condition may be violently exploded by a fuse containing 15 grains of fulminating mercury. Below 40° it freezes and cannot be so fired. The advantage of dynamite over nitro-glycerine lies altogether in the fact that the former is presented in another mechanical condition, more convenient and safer to use than the liquid form. The nitro-glycerine itself is the same chemically in either case. The same mixture of charcoal, sulphur, and saltpeter gives a very different effect if made up into large grains than if made up into small ones. Gun-cotton presents the most marked example of the effect of mechanical state, since it can be prepared in so many ways. If flame is applied to loose uncompressed gun-cotton it will flash off; if it is spun into threads or woven into webs, its rate of combustion may be so much reduced that it can be used in gunnery or for a quick fuse; powerfully compressed and damp, it burns slowly; dry gun-cotton may be exploded by a fulminate-fuse; wet, it requires an initial explosion of a small amount of dry, etc.

Confinement is necessary to obtain the full effect of all explosives. The most rapid explosion requires a certain time for its accomplishment. As the time required is less, the amount of confinement necessary is less. Then, with the sudden or violent explosives, the confinement required may be so small that its consideration may be practically neglected. For instance, large stones or blocks of iron may be broken by the explosion of nitro-glycerine upon their surfaces in the open air. Here the atmosphere itself acts as a confining agent. The explosion of the nitro-glycerine is so sudden that the air is not at once moved. Again, chloride of nitrogen is one of the most sudden and violent of all explosives. In its preparation it is precipitated from a watery liquid, and therefore is, when used, wet or covered with a very thin film of water. This thin film of water, not more than $\frac{1}{1000}$ of an inch in thickness, is a necessary and sufficient confinement, and if it is removed the explosive effect is much diminished. Gunpowder, on the other hand, requires strong confinement, since its explosion is comparatively slow. Thus, in firing a large charge of gunpowder under water, unless the case is strong enough to retain the gases until the action has become general, it will be broken, and a large amount of the powder thrown out unburned. This is often the case in firing large-grained powder in heavy guns. The ball leaves the gun before all the powder has burned, and grains or lumps of it are thrown out uninjured. The confinement needed by the slower explosives may be diminished by igniting the charge at many points, so that less time is required for its complete explosion.

In any explosive reaction the mode of bringing about the change exercises an important influence. The application of heat, directly or indirectly, is the principal means of causing an explosion. Thus, in gunnery, the flame from the percussion-cap or primer directly ignites the charge; so also a fine platinum wire heated by an electric current will ignite explosive material which is in contact with it. Friction, percussion, concussion, produce the same effect indirectly, by the conversion of mechanical energy into heat, which is communicated to the body to be exploded. When one explosive body is used as a means of firing another, it may be considered that the blow delivered by the gas suddenly formed from the firing-charge acts percussively upon the mass to be exploded. The particles of this gas are thrown out with great velocity; but meeting with the resistance of the mass around them, they are checked, and their energy is converted into heat. It is found, however, that the action of explosives on one another cannot be perfectly explained in this way. If the action were simply the conversion of energy into heat, then the most powerful explosive would be the best agent for causing explosion. But this is not the case. Nitro-glycerine is much more powerful than fulminating mercury; but 15 grains of the latter will explode gun-cotton, while 70 times as much nitro-glycerine will not do it. Chloride of nitrogen is much more violent than fulminating mercury, but larger quantities of the former than of the latter must be used to cause other explosions. Again, nitro-glycerine is fired with certainty by a small amount of fulminating mercury, while with a much larger amount of gunpowder the explosion is less certain and feebler. In these cases it is evident that the fulminating mercury must have some special advantage, since it produces the desired effect more easily than the others. It may be considered that the fulminating mercury sets up a form of motion or vibration to which the other bodies are sensitive. Just as a vibrating body will induce corresponding vibrations in others, so the peculiar rate of motion or wave of impulse sent out by the fulminating mercury exerts a greater disturbing influence upon the molecules of some bodies than that derived from other substances.

An explosive molecule is unstable and very susceptible to external influences. Its atoms are in a nicely balanced equilibrium, which is, however, more readily overturned by one kind of blow than another. The explosive molecule takes up the wave of impulse of the fulminate, but the strain is too great, and its own balance is destroyed. So a glass may stand a strong blow; while a particular note or vibration will break it. In the case mentioned above, of gun-cotton affected by nitro-glycerine or fulminate, the explosion of the nitro-glycerine is strong enough to tear and scatter the gun-cotton, but the blow, though very powerful, is not one that the gun-cotton is sensitive to; on the other hand, the fulminate blow, though weaker, readily upsets the molecule of the gun-cotton. In addition, the explosion proceeds very differently when brought about in this way than when caused by simple inflammation. When a mass of explosive is ignited by a flame, the action extends gradually through it; but if it is exploded by a blow, acting in the manner above described, it is plain that the explosion will be nearly instantaneous throughout, since the impulse will be transmitted through the mass with far greater rapidity than an inflammation proceeding from particle to particle. The explosive reaction will then proceed much more rapidly, and the explosive effect will be more violent.

The phenomenon of the explosion of powder may be divided into three distinct parts, viz., *ignition*, *inflammation*, and *combustion*. By ignition is understood the setting on fire of a particular point of the charge; by inflammation, the spread of the ignition from one grain to another; and by combustion, the burning of each grain from its surface to center. See *Combustion*, *Detonation*, *Explosive Agents*, *Gunpowder*, *Ignition*, and *Inflammation*.

EXPLOSIVE AGENTS.—There is some question as to the influence, direct or indirect, upon modern civilization of the introduction of explosive agents for the purpose of war. Some eminent authors have gone so far as to consider the invention of gunpowder as next in importance, in its ultimate effects, to those of printing and the application of steam-power. However this may be, it is well to remember that explosive substances are now of immense utility in the arts of peace; indeed, it is not too much to say that without their aid many of the great engineering enterprises of the present day would either be impossible, or else have to be carried out at a vast additional expenditure of time and labor. The germ of all the knowledge which we possess of explosive reaction undoubtedly lay in the probably accidental discovery, many years ago, of the deflagrating properties of the natural substance niter or saltpeter (KNO_3), when in contact with incandescent charcoal. By distilling niter with oil of vitriol the alchemists obtained a corrosive fluid which they called *aquafortis*, now known as nitric acid (HNO_3), which parts with its oxygen even more rapidly than saltpeter; so that if the strongest nitric acid be poured upon finely powdered charcoal, the latter takes fire at the ordinary temperature. Somewhat less than half a century back it was discovered by some French chemists that upon treating various organic substances, such as starch, the sugars, cotton fabrics, and even paper, with concentrated nitric acid under proper precautions, the chemical constitution of the substances underwent a great change, and they became endowed with violently explosive properties, while remaining for the most part unaltered in external characteristics. To this discovery we owe a distinct class of explosive compounds, the most powerful for practical purposes as yet known. Examining into those principles of constitution and action which are more or less common to all explosive substances, we may define, for our purpose, the term "explosive" as the sudden or extremely rapid conversion of a solid or liquid body of small bulk into gas or vapor, occupying very many times the volume of the original substance, and, in addition, highly expanded by the heat generated during the transformation. This sudden or very rapid expansion of volume is attended by an exhibition of force more or less violent according to the constitution of the original substance and the circumstances of explosion. Any substance capable of undergoing such a change upon the application of heat or other disturbing cause is called an explosive agent. The most explosive substances that are practically the most important essentially contain carbon, oxygen, and nitrogen, the last always existing in a state of feeble combination with the whole or part of the oxygen, and thus creating that condition of unstable chemical equilibrium which is necessary. When explosion takes place the nitrogen parts with its oxygen to the carbon, for which it has a greater affinity, forming carbonic acid (CO_2) and carbonic oxide (CO) gases, the combination being accompanied with great generation of heat, and the nitrogen being set free. In most explosives there is also hydrogen accompanying the carbon, and by its combustion producing an extremely high temperature: it combines with part of the oxygen to form water in the form of greatly expanded vapor. Other subordinate elements are often present; in gunpowder, for instance, the potassium binds the nitrogen and oxygen loosely together in the state of saltpeter, and there is sulphur, a second combustible whose oxidation evolves greater heat than that of carbon. When chlorate of potash is present the chlorine plays the part of nitrogen, and is set free in the gaseous state. Two very unstable and practically useless explosive substances, the so-called chloride and iodide of nitrogen, contain neither carbon nor oxygen; but their great violence is equally caused by the feeble affinities of nitrogen for other elements, large volumes of gaseous matter being suddenly disengaged from a very small quantity of a liquid and solid body respectively.

Explosives may be conveniently divided into two distinct classes—(1) Explosive Mixtures, and (2) Explosive Compounds. The first class consists of those explosive substances which are merely intimate mechanical mixtures of certain ingredients, and which can be again separated more or less completely by mechanical means not involving mechanical action. These ingredients do not, as a rule, possess explosive properties in their separate condition. There are, however, explosives which might also be classed in both categories; for example, *picric powder* is composed of ammonium picrate and saltpeter, the former of which contains an explosive molecule, but is mixed with the latter to supply additional oxygen and thus increase the force. If a substance that will burn freely in air, combining gradually with the oxygen of the atmosphere, be ignited in pure oxygen gas, the combustion will be much more rapid and the amount of heat generated greater at the ordinary atmospheric pressure. If it be possible to burn the substance in a very condensed atmosphere of oxygen, we can readily imagine the combustion as very greatly accelerated, and therefore increased in violence; this is what is ordinarily effected by an explosive "mixture." A combustible body and a supporter of combustion are brought into extremely close contact with one another by means of intimate mechanical mixture; also, the supporter of combustion, or oxidizing agent, is present in very concentrated form, constituting what may be termed a magazine of condensed oxygen, solid or liquid. In the case of the explosion of a definite chemical compound, the change may be considered as the resolution of a complex body into simpler forms. This is not, however, always the case when a mechanical mixture is concerned; gunpowder, for example, may be said to contain two elementary substances, carbon and sulphur, not in chemical union. The chief explosive mixtures may be subdivided into "nitrate mixtures" and "chlorate mixtures." In the nitrates, the oxygen is held in combination with sufficient force to need a powerful disturbing cause to separate it, so that mixtures made from nitrates do not explode very rapidly, and their action is comparatively gradual; they are not sensitive to friction or percussion, and hence are to a great extent safe. Any of the nitrates will form explosive mixtures with combustible substances, but nitrate of potash (KNO_3) is the only one practically employed. The nitrate of soda, called "cubical" or Chili saltpeter, has been used, but absorbs moisture from the air so readily as to give very inferior results. Gunpowder may be taken as the representative of the nitrate explosive mixtures. Picric powder, already referred to, has been proposed by Abel for use as a bursting-charge for shells, as being more powerful than a corresponding charge of gunpowder, equally safe as regards friction or percussion, and less hygroscopic; it consists of two parts ammonium picrate and three parts saltpeter, incorporated, pressed, and finished very much as ordinary gunpowder. The chlorates part with their oxygen far more readily than the nitrates, the strong affinities of chlorine for the metals coming into play, and consequently chlorate mixtures are very sensitive to friction and percussion, and explode with great violence; chlorate of potash ($KClO$) is the only one used. Very many chlorate mixtures have been made, some of which are employed in fireworks. "White gunpowder" is a mixture of two parts chlorate of potash, one of yellow prussiate of potash, and one of sugar; it is exploded very easily by friction or percussion. The most important chlorate mixtures are those used for igniting other explosives, such as the composition for friction-tubes for firing cannon, percussion-cap composition, and percussion-fuses for bursting shells on impact; it is sometimes mixed with sulphur, as a combustible, and sometimes with black sulphide of antimony, which gives a longer flame.

In an explosive compound the elements are all in chemical combination, presenting a definite explosive "molecule," which contains, so to speak, both the combustible and the supporter of combustion in the closest possible union; we can therefore understand its action being much more sudden and violent than that of the most intimate mechanical mixture. The chief explosive compounds are formed from some organic substance containing carbon, hydrogen, and oxygen, by introducing into it, through the action of concentrated nitric acid, a certain portion of nitric peroxide (NO_2), in substitution for an equivalent amount of hydrogen. A new compound differing outwardly very little, if at all, from the original substance is thus formed, but in a very unstable state of chemical equilibrium, because of the feeble union of the nitrogen and oxygen in the NO_2 molecule. A slight disturbing cause brings into play the stronger affinity of the carbon and hydrogen for the large store of oxygen contained in the new compound. Gun-cotton and nitro-glycerine are the leading members of this group, being produced in a precisely similar manner by the substitution of three molecules of NO_2 for three atoms of hydrogen (H). As those explosives will be elsewhere described in detail, we give the formation as a representative member of the group of nitro-phenol or picric acid by treating phenol or carbolic acid with a mixture of nitric and sulphuric acids, the latter being required to absorb the water and preserve the full strength of the nitric acid:

Carbolic acid. Nitric acid. Picric acid. Water.

$$C_6H_6O + 3HNO_3 = C_6H_3(NO_2)_3O + 3H_2O$$

The formula of the product may be empirically written $C_6H_3N_3O_7$; it is, like gun-cotton and nitro-glycerine, a *tri-nitro* substitution product. Only the picrates or salts of picric acid formed with potassium or ammonium are used in practice as possessing more force than the uncombined acid. From starch may be obtained, in a strictly analogous manner, an explosive called *xyloidine*, which is a *bi-nitro* product, two molecules of nitric peroxide being substituted for two atoms of hydrogen. In the case of *nitro-mannite*, an explosive made from mannite, one of the sugars, as many as six molecules of the NO_2 are inserted. The number of nitro-substitution products is very great, many of them being more or less violently explosive. The fulminates are among the most violent of all explosive compounds, their chemical sensibility being very small. Sudden in action, their effect is great locally; thus they are well adapted to the purpose for which alone they are practically used, of igniting or upsetting the equilibrium of other explosives. Fulminate of mercury is produced by adding alcohol (C_2H_6O), under great precautions, to a solution of mercury in nitric acid; a gray crystalline precipitate is obtained, very heavy (sp. gr. 4.4), and so sensitive to friction or percussion that it is kept in the wet state. The results of analysis show one atom of mercury and two each of carbon, nitrogen, and oxygen; so that the formula may be empirically written $HgC_2N_2O_2$, or perhaps more correctly $HgO.C_2N_2O$; the chemical factor C_2N_2O is called *fulminic acid*, but has never been produced separately. Opinions differ as to the precise "rational" formulæ of the fulminates, some chemists considering their process of formation to be similar to that of the nitro-substitution products. It will be observed that two atoms of nitrogen take the place of hydrogen, being the ratio of combining proportions of those elements. The products of combustion are carbonic oxide, nitrogen, and metallic mercury, and the violence of action is due to the sudden evolution of a volume of gas and vapor very large in comparison with that of the substance, its density being so great. This fulminate enters into the composition used for percussion-caps and electric fuses; its practical value has of late years been immensely increased by the discovery of its power even in very small quantities to produce the almost instantaneous decomposition of several explosive substances. Fulminate of silver is prepared in a similar manner, but, being far more sensitive, is of little practical value; it is used in very minute quantities in making such toys as detonating crackers.

It may be generally concluded that the amount of force exerted by an explosive substance depends upon (1) the *volume of gas or vapor* produced by the transformation compared with that of the original substance; and (2) the *temperature of explosion*, which determines the extent to which the gases are expanded, or their tension increased; or in other words, the explosive force is directly proportional to the heat of combustion, and the volume of gas and vapor calculated at 0° C. and 7.60 mm. pressure, and *inversely* proportional to the specific heat of the mixed products. It has been supposed by Berthelot and others that the volume of gas produced may possibly be still further increased by the partial or total "dissociation" of the compound gases at the high temperatures concerned; for example, that the carbonic acid (CO_2) may be decomposed into carbonic oxide (CO) and oxygen, or the aqueous vapor into oxygen and hydrogen. However, Nobel and Abel demonstrate that in the former instance the loss of temperature consequent upon the absorption of heat by the decomposition would more than compensate for the increase of volume by dissociation. It must also be remembered that if the temperature be extremely high, so also is the pressure under which dissociation must take place. We may therefore consider that it has no sensible influence upon the explosive force. It is most important to distinguish between explosive force and explosive effect, the latter in great measure depending upon the rapidity with which the metamorphosis takes place, while the same amount of force may be exerted suddenly or gradually. We may, therefore, consider that the explosive effect varies *directly* as the volume of gas produced and the temperature of explosion, and *inversely* as the time required for the transformation. But the time, and, to a certain extent, the products and temperature, will vary with (*a*) the physical state of the explosive substance; (*b*) the external conditions under which it is fired; (*c*) the mode of firing or exploding. The physical or mechanical state of the explosive substance has a most important bearing upon the effect obtained from it. To prove this it is only necessary to point to the very different results given by gunpowders made with the same proportions of the three ingredients, but varying in density, and in shape and size of grains or pieces. Gun-cotton is even more affected by variations in mechanical condition. In the form of loose wool, it burns so rapidly that gunpowder in contact with it is not inflamed; plaited or twisted tightly, its rate of combustion in air is greatly modified. This is due to the fact that the inflammable carbonic oxide, which is evolved by the decomposition from the want of sufficient stored-up oxygen to oxidize completely all the carbon of the gun-cotton, cannot penetrate between the fibers and accelerate the combustion, but burns with a bright flame away from the surface of the twisted cotton; when the yarn is yet more compressed by any means, the temperature is not kept up to the height necessary for the combustion of the carbonic oxide, so that it escapes unconsumed, abstracting heat and yet more retarding the rate of burning. For the same reason, pulped and compressed gun-cotton burns comparatively slowly in air, even when dry; in the wet state it merely smoulders away, as the portion in contact with the fire successively becomes dried. Yet this same wet compressed gun-cotton can be so used as to constitute one of the most powerful explosives known. It is well known that gunpowder behaves differently when in the open air and under strong confinement; not only the rate of burning, but even, to a certain extent, the products of combustion are altered. We have discussed the effect of tightly plaiting or compressing gun-cotton; but when confined in a strong envelope, the whole of the inflamed gas, being unable to escape outwards, is forced into the interstices under immense pressure, and the decomposition is greatly accelerated. The amount of confinement or restraint needed by any explosive depends, however, upon the nature of the substance and the mode of exploding it, becoming very much less as the transformation is more rapid, until it may be said to reach the vanishing-point. For example, the very violent explosive chloride of nitrogen is usually surrounded, when exploded, with a thin film of water. Abel states that if this film, not exceeding $\frac{1}{1000}$ inch in thickness, be removed, the explosive effect is much lessened. Nitro-glycerine, again, when detonated by a fulminate, is sufficiently confined by the surrounding atmosphere. By the same means, gun-cotton may explode unconfined if compressed, the mechanical cohesion affording sufficient restraint. In the case of wet compressed gun-cotton, which can be detonated with even fuller effect than dry, the mechanical resistance is greater, the air-spaces being filled with incompressible fluid.

The manner in which the explosion is brought about has a most important bearing upon the effect produced. This may be done by the direct application of an ignited or heated body, by the use of an electric current to heat a fine platinum wire, or by means of percussion, concussion, or friction, converting mechanical energy into heat. A small quantity of a subsidiary explosive, such as a composition sensitive to friction or percussion, is often employed, for the sake of convenience, to ignite the main charge, the combustion spreading through the mass with more or less rapidity, according to the nature of the substance. Although subsidiary or initiatory explosives were at first used merely to generate sufficient heat to ignite the charge, and are often still so employed, they have of late years received an application of far wider importance. Mr. Alfred Nobel, a Swedish engineer, while endeavoring to employ nitro-glycerine for practical purposes, found considerable difficulty in exploding it with certainty; he at length, in 1864, by using a large percussion-cap, charged with fulminate of mercury, obtained an explosion of great violence. This result led to the discovery that many explosive substances, when exploded by means of a small quantity of a suitable initiatory explosive, produce an effect far exceeding anything that can be attributed to the ordinary combustion, however rapid, of the body in question; in fact, the whole mass of the explosive is converted into gas with such suddenness that it may, practically, be considered instantaneous. This sudden transformation is termed "detonation." Of the substances capable of producing such action, fulminate of mercury is the most important. Some explosives appear always to detonate, in whatever manner they may be exploded, such as chloride and iodide of nitrogen; the explosive effect is therefore much greater than that of a slower explosive substance, although their explosive force may be less. Again, other substances, such as gun-cotton and nitro-glycerine, are detonated or not, according to the mode of explosion. Indeed, Abel has proved that most explosives, including gunpowder, can be detonated, provided the proper initiatory charge be employed. Roux and Sarrau have divided explosions into two classes or orders—"detonations" or explosions of the first order, and "simple explosions" of the second order. They made a series of experiments with the object of determining the comparative values of various explosive substances, detonated and exploded in the ordinary manner; the method employed was to ascertain the quantity of each just sufficient to produce rupture in small spherical shells of equal strength. These experiments, although valuable, cannot be considered as affording a precise method of comparison; the results would be affected, *inter alia*, by the impossibility of insuring that the shells were all of the same strength—a point of great importance, considering the very small weights of each explosive used; also, the rate of combustion, and therefore the explosive effect, of gunpowder is materially affected by its mechanical condition, so that different powders would give a varying standard of comparison. However, they afford fair evidence that, when detonated, gun-cotton has about six times, and pure nitro-glycerine about ten times, the local explosive effect of gunpowder simply ignited in the ordinary manner; nitro-glycerine is usually employed in the form of "dynamite," mixed with some inert absorbent substance, so that its power is proportionately reduced.

The rationale of detonation is not yet understood. If the transformation were due merely to the mechanical energy of the particles of gas, liberated from the initiatory charge at a tremendous velocity, being converted into heat by impact against the mass of the explosive substance, then it would follow that the powerful explosive would be the best detonating agent. This, however, is not the fact; for a few grains of fulminate of mercury in a metal tube will detonate gun-cotton, whereas nitro-glycerine, although possessed of more explosive force, will not do so unless used in large quantities. The fact of its being possible to detonate wet gun-cotton is also a proof that the action cannot be due to heat alone. It would rather seem to be what Professor Bloxam terms "sympathetic" explosion. The experiments of Abel, as well as those of Champion and Pellet in France, appear to indicate a vibratory action of the detonating agent upon the ultimate particles of the substance to be exploded. An explosive molecule is most unstable, certain very delicately balanced forces preserving the chemical and physical equilibrium of the compound. If these forces be rapidly overthrown in succession, we have explosion; but when, by a blow of a certain kind, they are instantaneously destroyed, the result is detonation. Just as a glass globe may withstand a strong blow, but be shattered by the vibration of a particular note, so it is considered by some authorities that, in the instance cited, the fulminate of mercury communicates a vibration to which the gun-cotton molecule is sensitive, and which overthrows its equilibrium; it is not sensitive to the vibrations caused by the nitro glycerine, which only tears and scatters it mechanically. Although the action of detonation has been spoken of as instantaneous, and may practically be so considered, yet a certain infinitesimal duration of time is required for the metamorphosis; different substances possess, doubtless, different rates of detonation, for we can scarcely conceive of a mechanical mixture, such as gunpowder, being so sensitive to the action of the detonating impulse as a definite chemical compound, and the rate even varies slightly, for the same explosive, with its physical state. It has been shown by means of the chronoscope that well compressed gun-cotton, when dry, is detonated at a velocity of from 17,000 to 18,000 feet a second, or about 200 miles a minute; by using a small primer of dry gun-cotton, the same substance in the wet state may be detonated at an increased rate of from 18,000 to 21,000 feet a second, or about 240 miles a minute. The following table shows the potential energy, in foot-tons, calculated from the heat of combustion for each explosive, determined by Roux and Sarrau, in the experiments already referred to; that for gunpowder is the mean given by five kinds:

Explosive Substances.	Potential energy per lb. Foot-tons.
Gunpowder	480
Gun-cotton	716
Nitro-glycerine	1139
Picrate of potash	536
Picrate of potash and saltpeter	615
Picrate and chlorate of potash	781
Chloride of nitrogen	216

The above figures naturally direct our attention to the small amount of work stored up in even the most violent explosive substance, compared with the potential energy of 1 pound of coal, which is about 4980 foot-tons. Nobel and Abel point out that this great difference is due not alone to the fact that the coal draws its oxygen from the air, but also to the necessity that the explosive should expend a considerable amount of work in converting its condensed magazine of oxygen into gas, before it can combine with the carbon; further, with reference to the economical value of the work done, that the oxygen used by the coal costs nothing, whereas much expense is incurred in condensing the oxygen into the explosive substance. The practical value of any explosive must depend greatly upon the object to be attained. It is essential to distinguish between explosive force and effect; the more sudden the action the more local will be the effect produced, and hence the very violent explosive substances are useless as propelling agents for heavy guns or small-arms, since they would destroy the weapon before overcoming the inertia of the projectile. It is true that gun-cotton, prepared in various forms, and mixed with other substance to moderate its action, as well as a similar compound made from sawdust, an inferior form of cellulose, are sometimes used with small-arms; but in addition to a want of uniformity in action, the strain caused by such substances would be far too great in the large charges needed for heavy guns. Again, there are cases, even in mining or blasting operations, for instance, when it is desired to displace large masses of earth or soft rock, in which a comparatively slow explosive, such as gunpowder, would give better results than gun-cotton or dynamite. However, speaking generally, gunpowder in some one of its forms is far the most valuable as a propelling agent, while for destructive purposes the last-named substances are much more effective, especially when detonating. See *Explosion*, *Fulminates*, *Gun-cotton*, *Gunpowder*, *High Explosions*, *Nitro-glycerine*, and *Picrates*.

EXPLOSIVE MACHINES.—Very ancient machines of war employed by the Greeks. They were somewhat like the air-cannon or air-gun of the present day, but on a more gigantic scale.

EXPRESS RIFLE.—A modern sporting-rifle of great killing power. This rifle takes a large charge of powder and a light bullet, which gives a very high initial velocity and a trajectory practically a right line up to 150 yards, hence the term *express*. To increase the killing power of the bullet, it is made of pure lead and has a hollow point. Upon striking the object, the bullet spreads outwardly, inflicting a fearful death-wound. This arm is well adapted to meet the wants of those who hunt large game at short range. It is a modification of the Winchester, model 1876, and differs from it only in caliber (.50), and in the cartridge to which it is adapted. This last contains 95 grains of powder and a bullet weighing 300 grains. The cartridges may be loaded with hollow-pointed, solid, or split-pointed bullets, as may be desired. All these bullets weigh 300 grains each, and their shooting qualities are about equal. The primer is the No. 2½ Winchester. The powder used in loading the cartridges at the factory is United States Government Musket,

but any of the approved brands of powder suitable for large cartridges can be used. As has been noticed, the bullet having a high initial velocity, a very flat trajectory is obtained, and no change in sighting is required up to 150 yards, thus enabling the hunter to avoid missing the game through error in calculating distances. The recoil is not greater than that of a 12-gauge shotgun using ordinary charges; this model, as made up for the English market with a 22-inch barrel and with full-length magazine, weighs but 8½ pounds. If desirable, a small explosive cartridge can be dropped into the cavity in the point, making it an explosive bullet. A caliber as large as .57 is much used in England, but the .50 caliber is considered sufficient in the United States. See *Winchester Rifle*.

EXPUGNABLE.—In a military sense, a term for that which is capable of being taken by assault, forced, or conquered.

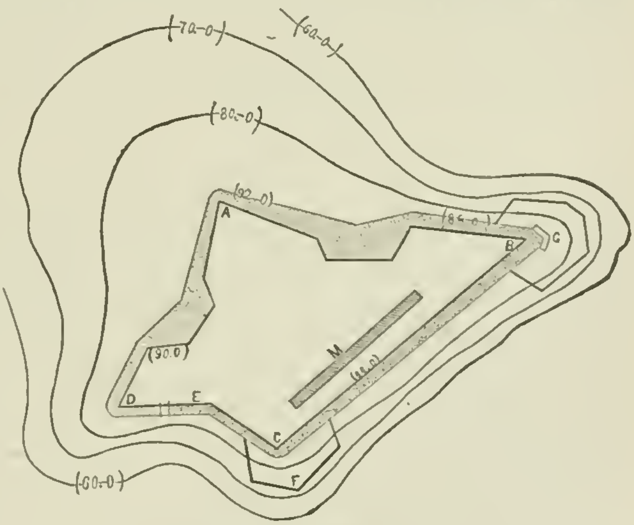
EXTEND.—A term peculiarly applicable to light-infantry movements when the files are frequently loosened and the front of the line extended for the purpose of skirmishing. When the divisions of a column are made to occupy a greater space of ground, they are said to extend their front. See *Extended Order*.

EXTENDED ORDER.—A light-infantry maneuver which is frequently practiced. It comprehends the opening of files of a battalion or a company standing two deep, so as to have just space enough for one man between each two. The battalion or company, after it has obtained all its relative distances and been halted, is fronted, and each rear-rank man springs into the vacancy when the word of command is given.

EXTERIOR CREST.—In fortification, the crest of the exterior slope of a parapet. See *Exterior Slope* and *Fortification*.

EXTERIOR DEFENSES.—Detached works should not only receive a strong profile, but have accumulated in their front every accessory obstruction that will best impede the assailant in an attempt at an open assault, and if not flanked from the parapet be provided with secure ditch-defenses. The arrangement for the armament should be of the most substantial character for heavy guns and mortars. Bomb- and splinter-proof shelters should be provided for the security and lodging of the garrison, and in works open at the gorge these should be placed across the gorge and be loop-holed to meet an assault in the rear. If the ground in advance of these works is not well swept by their fire, or that of the connecting intrenchments, the ordinary trench, now better known as rifle-pits, should be made for this service. Besides these, good covered communications for field-guns should be arranged so that batteries may be speedily moved from point to point, where their services may be most needed. These covered-ways should also be arranged for the use of musketry. The plan of these works will depend upon the character of their site and the more or less exposed position of it to the fire of the assailant. For the most important, bastioned forts will be the best; for others, the star-fort redoubt; or simply lunettes or redans will suffice. No specific rules can be laid down, as everything must depend on the judgment and skill of the engineer charged with planning the defenses.

The drawing represents the topography of a site, and the general plan of a fort for its immediate defense, and in reciprocal defensive relations with other works on its flanks. The fronts A B and A D are bastioned, and so placed that the fire from their faces and curtains, armed with heavy guns, can sweep the approaches on the collateral works; their flanks, armed with guns of smaller range, sweeping the principal approach to the work and flanking the ditches of the salient A. The front D C, to suit the configuration of the ground, is tenailled, and the front B C, for the same reason, is simply a right line, with only sufficient relief to sweep the approaches in front and be secure from a fire of musketry. For the better flanking of the ditch of the face at the salient B and the front B C, a counterscarp-gallery is placed in front of B. Rifle-pits are arranged at F and G to sweep the steep ground in advance of the fronts A B, B C, and C D. As the site admitted of some discretion in fixing the salient A, and the direction of the two fronts A B and A D, these are supposed to have been so determined as to avoid all enfilading and re-



Plan of Exterior Defenses of a Fort.

verse views on these two fronts. The command of these two fronts from A, each way to the opposite flanks, is supposed to be so regulated as to sweep the approaches on the two fronts and to cover all the interior from plunging fire. The outlet is at F, and a bridge leads from it across the ditch to the road which passes around the salient D, along the ridge in front of A. M represents the bomb-proof barrack, covered in front by the parapet and arranged as a keep.

In the exercise of his judgment the engineer will be called upon to make a particular study of and draw up memoranda on the general plan of defense for the whole position to be occupied, in which he will have to consider its extent and its topographical and military features; the side towards which it must be particularly fortified; the defensive and offensive character of the fortifications best adapted to it; its most striking tactical points both absolutely and relatively to the general plan of defense; the number of troops by which it is to be occupied; and the time in which, with the means at his disposal, the fortifications can be erected. These general points having been settled, the next step will be to consider the most suitable kind of work for each point, taking into account all natural and artificial obstructions that will contribute to the defense, the tactical relations of each work to the others, and the best distribution of the troops for each one. The discussion of the peculiar features of each work as to its profile, defilement, and construction will finally be fixed in accordance with the natural and artificial features of the site exterior to the works, the nature of the ground itself, and the disposable means that the locality itself may furnish for the construction of the work. All of this demands, on the part of the engineer, a thorough knowledge of general principles and an acquaintance with all the details and resources of his art. See *Fortification*.

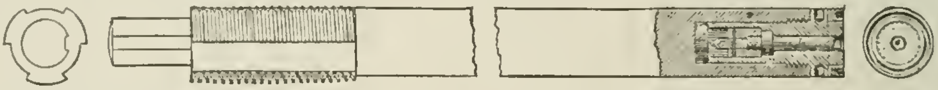
EXTERIOR FORM OF CANNON.—The exterior form of cannon is determined by the variable thickness of the metal which surrounds the bore at different points of its length. In general terms, the thickness is greatest at the seat of the charge, and least at or near the muzzle. This arrangement is made on account of the variable action of the powder and projectile along the bore, and the necessity of disposing the metal in the safest and most economical manner; or, in other words, to proportion it according to the strain it is required to bear. It has been proposed to determine the pressure of the powder at the different points of the bore by supposing all the gases evolved in the first moment of combustion, and, as the space behind the projectile increased, applying Mariotte's law, that the tension of gas is proportional to its density, which, in turn, is inversely proportional to the space it occupies. This method of determining the pressure gives a very rapid taper to the exterior; and however well it may answer for cast-iron cannon, is unsuitable for those made of bronze; which are found in practice to burst in the chase, in consequence of the enlargement of the bore from the striking of the projectile against its sides. About the year 1841 Colonel Bomford devised a plan for determining this pressure by direct experiment. It essentially consisted in boring a number of small holes through the side of a gun, at right angles to its axis, the first hole being placed at the seat of the charge, and the others at intervals of one caliber. A steel ball was projected from each hole, in succession, into a target or ballistic pendulum by the force of the charge acting through it; and the pressures at the various points were deduced from the velocities communicated to the balls; it was by this means that the form of the columbiads was determined. This plan has been lately tried in Prussia with great care and success. Instead of the projectile, Captain Rodman uses a steel punch which is pressed by the force of the charge into a piece of soft copper. The weight necessary to make an equal indentation in the same piece is then ascertained by the "testing-machine," or a machine employed to determine the strength of cannon-materials. This instrument is known as the "pressure-piston," and is used in proving powder to measure the strain which is exerted on the bore of the eprouvette or gun.

In estimating the effect of any force upon a yielding material to which it may be applied, the rate of application, or the time which elapses from the instant when the force begins to act until it attains its maximum, should not be neglected; for, with equal ultimate pressures per square inch of surface, that powder will be most severe upon the gun which attains this pressure in the shortest period of time after ignition. The smaller the grain the more rapid will be the combustion of any charge of powder (other things being equal), and hence the greater will be the strain on the gun in which it is burned. The strains to which all fire-arms are subjected are four in number, viz.: 1st. The *tangential* strain, which acts to split the piece open longitudinally, and is similar in its action to the force which bursts the hoops of a barrel. 2d. The *longitudinal* strain, which acts to pull the piece apart in the direction of its length. Its action is the greatest at or near the bottom of the bore, and least at the muzzle, where it is nothing. These two strains increase the volume of the metal to which they are applied. 3d. A strain of *compression*, which acts from the axis outward, to crush the truncated wedges of which a unit of length of the piece may be supposed to consist. This strain compresses the metal and enlarges the bore. If the metal were incompressible, no enlargement of the bore would result from crushing; and any enlargement of the bore caused by the action of the tangential force would be accompanied by a corresponding enlargement of the exterior diameter of the piece; and hence the absolute extension of the metal, at the inner and outer surfaces of the gun, would be inversely as the radii of these surfaces. 4th. A *transverse* strain, which acts to break transversely, by bending outward the *staves* of which the piece may be supposed to consist. This strain compresses the metal on the inner, and extends it on the outer surface. The resistance which a bar of iron, supported at its extremities, will offer to a pressure uniformly distributed over it, is directly as the square of its depth, and inversely as the square of its length. See *Cannon* and *Ordnance*.

EXTERIOR SIDE.—The side of a polygon upon which a front of fortification is formed. Taking the height of parapet at 8 feet and the depth of the ditch at 6 feet, the relief of 14 feet will be the least used; taking the height at 12 feet and the depth at 12, the corresponding relief of 24 feet will be the greatest used. Assuming the superior slope at $\frac{1}{6}$, the least length of curtain for the least relief is 56 yards; the least length for the greatest relief is 96 yards. For a curtain of 56 yards in length, the exterior side must be about 125 yards long; for the curtain of 96 yards, the exterior side must be 250 yards long. The least length of the exterior side will therefore be between 125 and 250 yards, depending upon the relief of the work. The greatest length of the exterior side depends upon the length given to the line of defense. If the weapon used to arm the flanks is the rifled musket—the weapon now used by infantry—its close and effective range determines the length of the line of defense. The limit of accurate aim for the ordinary soldier is about 300 yards. Assuming this to be the length of the line of defense, the exterior side will be about 400 yards long, and will be the greatest length ordinarily used. See *Field-fortification*.

EXTERIOR SLOPE.—In a fortification, the surface connecting the superior slope with the ground in front. The exterior slope *is the same that the earth naturally assumes*. Any means used to make it steeper would be injurious; because such would be soon destroyed by the enemy's fire, and the earth giving way, the necessary thickness of the parapet would be diminished. See *Field-fortification*.

EXTERNAL PRESSURE-GAUGE.—A form of pressure-gauge variously employed. The drawing shows a form for taking pressures at the bottom or at any point along the surface of the bore. The length of the plug in which the gauge is screwed is such that its bottom reaches to and forms a part of the bore at the position where the pressure is to be taken. The plug has a sectional screw to facilitate its insertion or withdrawal,



External Pressure gauge.

and the rim of the plug is provided with a gas-check to cut off the gas from the surface of the plug. See *Pressure-gauge*.

EXTORTION.—Under the modern laws of war, honorable men no longer permit the use of any violence against prisoners in order to extort information or to punish them for having given false information.

EXTRACTOR.—An instrument used in extracting a projectile from a muzzle-loading rifled gun. That introduced into the service for the various calibers of projectiles is constructed to act independently of the grooves of the gun. The term *extractor* is given to some other articles of artillery stores, such as the extracting implement used with the Gatling gun, and the instrument used in extracting a fuse from a shell.

EXTRADITION.—The Federal Constitution provides that "A person charged in any State with treason, felony, or other crime, who shall flee from justice and be found in another State, shall, on demand of the executive authority of the State from which he fled, be delivered up to be removed to the State having jurisdiction of the crime." As to foreign countries, extradition is regulated by special treaties, and the United States has such treaties with Great Britain, France, the Hawaiian Islands, most of the States now forming the German Empire, and with that Empire, Austria, Sweden and Norway, Italy, Switzerland, Venezuela, the Dominican Republic, Nicaragua, Hayti, and Mexico. These treaties provide for extradition in cases of the higher crimes, such as murder, assault with intent to kill, piracy, arson, robbery, forgery, rape, embezzlement by public officers, burglary, etc. Proceedings in cases of extradition are carefully defined and guarded by law. Political offenders, even though making war upon their own Government, are not subject to extradition. There are some treaties made between the United States and several Indian tribes, recognized as nations or distinct communities, in some of which the Indians have stipulated to surrender to the Federal Authorities persons accused of crimes against the laws of the United States.

EXTRA DUTY.—Although the necessities of the service may require soldiers to be ordered on working-parties as a duty, Commanding Officers should bear in mind that fitness for military service by instruction and discipline is the object for which the army is kept on foot, and that they are not to employ the troops when not in the field, and especially the mounted troops, in labors that interfere with their military duties and exercises, except in case of immediate necessity, which should be forthwith reported for the orders of the War Department. Extra-duty men should attend the weekly and monthly inspections of their companies, and, if possible, one drill in every week. Private soldiers employed in hospitals as cooks and nurses continuously for a period exceeding ten days are paid the lowest rate of extra-duty pay, by the Paymaster, on the hospital muster-rolls. Enlisted men of the Ordnance and Engineer Departments, Hospital Stewards, and Ordnance and Commissary Sergeants, do not receive extra-duty pay, unless under special authority of the Secretary of War. The company artificers, farriers, blacksmiths, and wagoners receive no extra pay except when detailed on extra duty in the Quartermaster's Department, wholly disconnected with their companies. Soldiers detailed as Acting Superintendents of National Cemeteries while so acting are entitled to extra pay as Overseers. Signal Service men do not receive extra-duty pay unless specially directed by the Secretary of War. The following Signal Service men are authorized to receive extra-duty pay at the rate of thirty-five cents per day: Non-commissioned officers in charge of sections; Corporals and privates in charge of stations, or serving as operators; and repair-men on the United States telegraph lines carrying, or which may carry, commercial business. Soldiers employed as scouts are not to be paid extra-duty pay, it being a military duty to which they are liable. A prisoner undergoing sentence does not receive extra-duty pay. Enlisted men being liable to perform guard and other military duty are entitled to extra pay when employed on extra duty more than ten days in a month, though the employment may not have been continuous. Eight hours constitute one day's work for all persons who are employed and paid by the day, by or on behalf of the Government of the United States. This does not extend to persons who are paid regular salaries. Watchmen, clerks, messengers, and others, whose time may be necessary at any or all hours, are not considered to be embraced within the terms of the law. Men on extra-duty pay are held to such hours as may be expedient and necessary; but except in case of urgent public necessity, as in military operations, when they must work regardless of hours, not more than ten hours' labor should be required. But when more than eight hours' work is required in any one civil day, the soldier rendering the service will be paid for more than a day's labor, in proportion to the time actually employed. In ordinary cases the hours of work should be so regulated as to agree, as far as possible, with the hours established in civil work in each locality. See *Duty*.

EXTRAORDINARIES OF THE ARMY.—In the British service, the allowances to the troops beyond the gross pay in the Pay Office. Such are the expenses for barracks, marches, encampments, Staff, etc.

EXTRAORDINARII.—In the ancient Roman army, a select body of men consisting of the third part of the foreign cavalry and a fifth of the infantry. These were carefully separated from the other forces borrowed from the Confederate States, in order to prevent any treacherous coalition between them. From among the Extraordinarii a more choice body of men were drawn, under the name of *Ablecti*.

EXTREME RANGE.—The distance from the piece to the point at which the projectile is brought to a state of rest. *Greatest range of a piece* is the farthest distance to which it will throw a projectile, the piece being mounted on its appropriate carriage. All ranges are expressed in yards. In air, the maximum range, under all ordinary circumstances, is obtained from an angle not far from 34 degrees. See *Range*.

EYE-SPLICE.—A splice made by turning the end of a rope back on itself and splicing the end to the standing part, leaving a loop. See *Cordage*.

F

FABIAN.—Delaying; dilatory; avoiding battle, in imitation of Quintus Fabius Maximus Verrucosus, a Roman General who conducted military operations against Hannibal, by declining to risk a battle in the open field, but harassing the enemy by marches, counter-marches, and ambuscades.

FABRICATION OF FIRE-ARMS.—With the exception of swords and patent arms, all small-arms for the United States army and militia are made at the National Armory, now situated at Springfield, Mass. This Armory is under the general charge of the Chief of Ordnance, who, by the authority of the War Department, furnishes the models and prescribes the kind and quantity of work to be done; the operations are conducted by civilians. A principal requisite, in the manufacture of small-arms, is that similar parts of the same kind of arm, or *model*, shall be capable of interchange. This demands a higher degree of accuracy in the workmanship than can be attained by hand-labor, without great cost, and the consequence is that machinery is now very generally employed in this branch of manufacture. The principal operations of manufacturing arms are *welding, swaging, boring, turning, drilling, tapping, milling, cutting and filing, grinding, case-hardening, tempering*, and *polishing*. Welding and swaging are performed by blacksmiths; the other operations, by armorers or finishers. For the purpose of minutely investigating the fabrication of fire-arms, we will notice in detail the various processes and operations performed in the manufacture of the Springfield rifle, caliber .45 inch. The subject will be more readily embraced by following the work in detail through the forging department and subsequent operations.

Rolling barrels—A Springfield gun-barrel is made from a 2-inch round bar of decarbonized steel. The first operation is to cut the bar into lengths of 9.25 inches each; the second is to center both ends of each piece; the third is to drill a hole ⅝ inch diameter through the entire length of the piece, forming a tube, called a "barrel-mold," which, for a rifle, weighs 7 pounds, and a carbine 6 pounds. The mold is heated and then drawn out between grooved rolls. Each set of rolls has eight grooves, two of them cylindrical and six taper. In connection with the grooves eight mandrels are used, which vary in diameter of knob from .75 to .37 inch. Four molds are placed in a reverberatory furnace and brought to a red heat. A workm:n then thrusts the largest mandrel through one of them, while still in the furnace. He then carries it to the rolls, and placing the mandrel through the frame, introduces the end of the mold into the first of the cylindrical grooves. The action of the rolls is to draw the mold over the mandrel. The cylinder is straightened by striking it on a flat iron table, and placed in the furnace to be reheated. The molds are run through the first groove in succession, after which the second-sized mandrel is used. The cylinders are run through the second groove in the same manner. The remaining grooves are made of the same shape as the required barrel. The cylinders are passed breech foremost through these, precisely as before, each cylinder being reheated after passing through any one groove except the last one, through which it is passed three times to give the required form. A ninth groove is on the rolls, but it is only used when, as rarely happens, the barrel appears to be running a little short. When the first four molds have reached the third groove, four additional molds are placed in the furnace. Thus the supply is constant without risk of burning the metal. One hundred and fifty can be rolled per day of eight hours with one set of rolls. One roller and two helpers are required for each set of rolls. One furnace can heat molds sufficient for two sets of rolls. From 5 to 8 pounds of coal are used per barrel *Cutting off*—The barrel, after passing through the last groove and while still hot, is cut to a length of 33 inches for the rifle, and to 22¼ inches for the carbine, by a set of two circular saws. *Straightening*—The barrel is placed in the straightening-machine, which is composed of two dies each of the length and shape of the half-barrel, and which close upon each other as the workman turns the barrel about its axis with a pair of tongs. *Annealing*—The barrels are again placed in a reverberatory furnace, brought to a red heat, taken out, and packed in cast-iron boxes in alternate layers with fine charcoal. Each box contains about 80 barrels. This operation renders the barrels less brittle, and also makes them easier to turn, file, etc. They remain in the charcoal from three to five days before they are cool enough to be removed. *First straightening*—The barrels are then straightened partly on an anvil with a common hammer and partly under a drop-hammer. *First and second boring*—The barrels are now "first-bored" with two twist-augers, of .37 and .42 inch diameter respectively, in a swift boring-machine, and "second-bored" with a quadrangular auger ribbed with splints, to a caliber of .44 inch. In the first boring the augers are drawn through the bore rather than pushed. In the second and additional borings the cutting is done in both directions. *First milling*—The rough ends left by the circular saws are squared up in a hand milling-machine, shown in Fig. 1, the spindle of which carries a cone of several grades. *First turning*—The barrel is placed in a lathe and a portion at the breech is turned down to receive a "dog" (a contrivance for holding the barrel in the

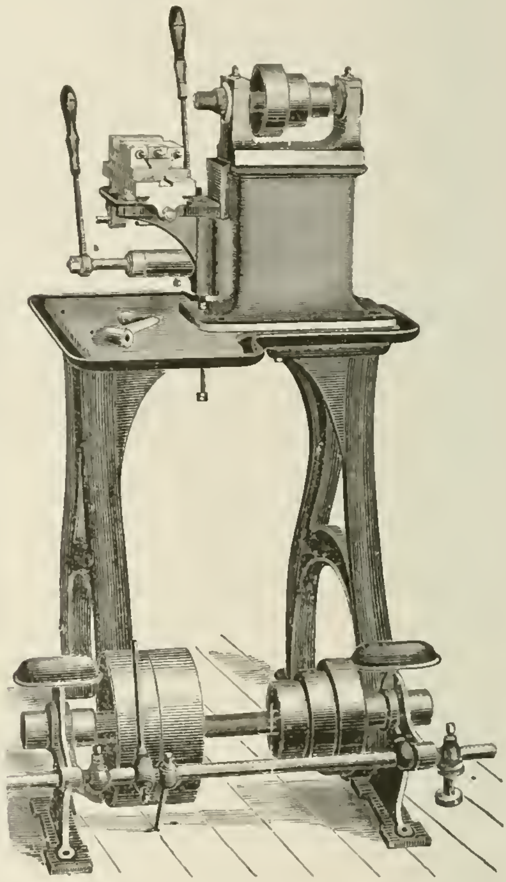


FIG. 1.

turning-lathes), after which a ring of Babbitt-metal is cast around the middle of the barrel. This ring is turned down smooth to give a bearing for a support which prevents the barrel from springing while the cutter is turning down the rough exterior. The lathe for this portion of the work is shown in Fig. 2. *Second turning*—One half the length of the barrel is now turned down, after which it is taken from the lathe, the ring knocked off, and the other half completed. During the latter half of the turning the support bears against the smooth surface of the part first turned off. *Second straightening*—The barrel is now straightened on the interior by the use of the anvil and hammer. The accuracy of this work is determined by holding the barrel up to the light and reflecting the image of a straight-edge from the surface of the bore. If the barrel be straight, the reflected image will be straight in all positions of the barrel. *Third turning*—The barrel is placed in a lathe and .05 inch turned off throughout its whole length. *Third boring*—It is again bored in a manner similar to the second boring, the caliber being brought up to

.4445 inch. *Second milling*—The muzzle is now milled for a few inches to the true taper to serve as a guide to the grinder. *Grinding*—The barrel is ground very nearly to its true size on a large and rapidly-revolving grindstone. *Proving*—At this stage the barrels are proved. About 40 are loaded with 280 grains of musket-powder, a paper wad, a lead slug weighing 500 grains, and a paper wad over all. The barrels are clamped down in a semicircular bed and fired by a train. The operation is repeated, except that the powder-charge is 250 grains. After each fire the letter P is stamped by an Inspector on the under side, near the breech, of all barrels which endure the test. To prevent mistakes the stamping is done before the barrels are removed from the proof-house. *Muzzle-filing*—The muzzle is filed to remove the roughness left by the milling, and to bring it to shape for receiving the bayonet-socket. It is done in the turning-lathe. *Third milling*—The breech end is squared up smoothly. *Sighting*—The barrel is placed in the milling-machine, and a seat for the front sight milled out. The ends of the seat are undercut, leaving the upper edges comparatively thin. The edges are turned up with a chisel and hammer and the roughly-formed sight pressed in the seat. cally through the spindle and pushes the cutters out more and more until the operation is completed. When the grooves are cut to the required depth the automatic device for feeding the rod ceases to act, a pawl being lifted from a ratchet by a spring. The cutters then move back and forth until the grooves are thoroughly polished. The pushing out of the cutters takes place just after they have passed clear through the barrel, so that the cutting is done as the spindle is withdrawn. An automatic arrangement also turns the barrel one third of a revolution about its axis each time the cutters leave the breech-end of the bore. The cutters then enter different grooves. By this means the grooves are made of equal widths and depths, since any little variation due to the size of a cutter is eliminated by the others. Each cutter enters all the grooves many times before the rifling is completed. *Second muzzle-filing*—The barrel is placed in a turning-lathe, and the muzzle is accurately filed in front and in rear of the sight. *Finishing muzzle*—The portion of the muzzle which is prevented by the sight from being filed while the barrel is revolving is filed off by hand. *Jigging front sights*—A jig is placed over the sight, and the sight is then filed down to size. *Sixth milling*—This consists in slightly rounding off

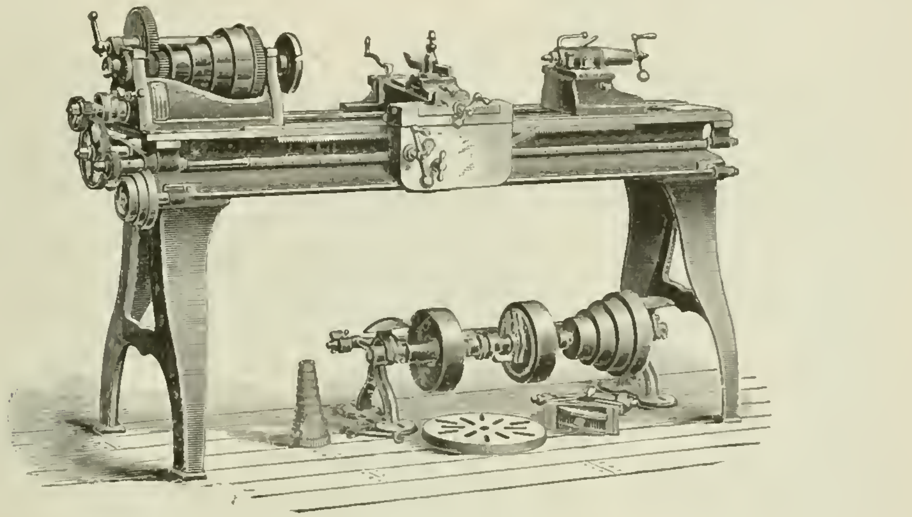

FIG. 2.

The edges are then driven down, bearing against the sight so as to hold it in position. The barrel is then carried to the brazing-room and the sight is brazed on. *Fourth milling*—The front end of the sight is milled off so that the required distance shall remain between the sight and the muzzle. *Front-sight filing*—This consists in filing around the sight after the brazing. *Fifth milling*—The muzzle-end is smoothly squared up. *Fourth boring*—Reams out the barrel to a caliber of .4465 inch. *Fifth boring*—Reams out the barrel to a caliber of .45 inch. *First polishing*—About 5 inches at the breech-end are polished on a buff-wheel. *Second polishing*—The barrel, placed in a vertical polishing-machine and held by the portion already polished, is moved rapidly up and down and at the same time turned about its own axis between clamps, the surfaces of which are covered with emery and oil. *Rifling*—The barrels are rifled in a machine specially prepared for this purpose. A hollow spindle, armed with three cutters, is moved uniformly through the barrel, entering at the muzzle. The spindle has also a uniform motion about its axis sufficient to cause one revolution in 22 inches. At the end of the stroke the motion is reversed and the spindle withdrawn. The cutters are let in the surface of the spindle and held by springs. A conical rod is moved automatithe corners or edges at muzzle. *Inspections*—The barrels are carefully inspected after rolling, first and second borings, third turning, third boring, second milling, grinding, proving, fourth and fifth borings, second polishing, rifling, second muzzle-filing, and sixth milling. These inspections are for ascertaining the quality of the work and material, and for gauging as to size.

The material from which the bayonet-blade is formed is a cast-steel bar, cross-section .625 inch square, the length of which is sufficient to bring up the weight to 14 ounces. *Cutting*—The bar is cut into suitable lengths by a large pair of shears worked by power, and is determined as follows: A tube containing water is capable of receiving 14 ounces of steel without causing the water to run over. The bar enters the tube, and when the water rises to the level the bar is cut off. The intention is that the same amount of stock shall be in each bar. *Neck-rounding*—Each piece thus cut off is heated and a small round head formed at one end, under a pony-hammer. A neck connects the head with the bar. *Rolling*—The bars are placed in a reverberatory furnace. When brought to a red heat a bar is taken out by a workman with a pair of tongs and inserted in the first of the nine grooves on the surface of the rolls. It is then inserted in each groove in succession up to the fourth, through which it is passed three times. It is then passed through each of the remaining grooves, after which it is inserted up to the neck in a cast-iron box filled with fine charcoal, where it undergoes annealing. No reheating is necessary throughout the whole operation. The first four grooves serve merely to draw out the bar, while the others flute the blade. *Neck-heading*—The head and neck are heated, the neck bent at right angles to the blade under a drop-hammer, and the head upset under a trip hammer, to form a broader surface for receiving the socket-plate. The socket-plate is of wrought-iron, forged and trimmed from a piece 2.35 inches square by ¼ inch in thickness. It is pickled in oil of vitriol and water heated by steam, before it is welded to the blade. *Socket welded on*—The socket-plate and head of the blade are heated, the plate placed on the head, and quickly welded to it by a trip-hammer. The socket is reheated, trimmed by a pair of shears, and curved over a mandrel by a hand-hammer. *Lap-welding*—The socket is reheated, a mandrel inserted, and the edges welded together in a die under a trip-hammer. The socket is again heated, placed in a die under another trip-hammer and brought to shape. *Neck-swaging*—The socket and neck are again heated and their position with respect to the blade determined by a drop-hammer forcing the different parts into a die. *Annealing socket*—The bayonets are placed in the annealing-furnace, and the blades for the greater portion of their length passing downward between the bars of a grate. Charcoal is laid on the grate, over the socket-necks and upper portion of the blades. A fire is started and the parts mentioned are heated to a red heat. The charcoal burns away and the metal cools slowly, remaining in the furnace about 48 hours. The lower portions of the blades do not require annealing, as they are annealed immediately after rolling. *Pickled*—The bayonets are vitrioled as before explained. *First boring*—The sockets are roughly bored nearly to size. *First turning*—The exterior of the socket is turned off except at the bridge. *Burring sockets*—The fin at each end of the socket is filed off by hand. *Straightening blade*—The blade is straightened on an anvil preparatory to milling. *First facing*—The face of the blade next to the neck is now milled off for a distance of about three inches. *Milling blade*—The grooves and edges are milled, bringing the blade nearly to the required size. *Punching points*—The end of the blade is punched in a die nearly to shape and size. *Heeling and pointing*—The point of the blade and the sides at the point of junction with the neck are milled to the required form. *Tempering*—The blade is heated to a cherry red and then plunged into brine. This renders it very hard and brittle. The blade is then coated with sperm oil and heated until the oil is burned off, when it is left with a spring temper. It is then straightened on an anvil. *Buffing edge*—The edges are straightened and smoothly buffed on a horizontal buff-wheel. *Buffing face*—The face of the blade is buffed to remove the rough surface left in milling. *Buffing back and point*—The three edges of the point are also buffed to give a smooth surface for polishing. *First punching*—The socket is placed on a mandrel containing a die, and the slot is punched out except the portion through the arch. *Second boring*—The socket is bored up nearly to its true size. *Second turning*—The exterior of the socket is turned down except at the arch. *First milling socket*—The ragged ends of the socket are milled off and the length of the socket brought down to gauge. *Third turning*—The exterior of the socket is turned off at the arch. *Second punching*—The socket is punched through the arch. *Milling neck*—The neck is milled to shape and nearly to size. *Buffing neck*—The neck is buffed to remove roughness left by the milling-tools. *Grinding blade*—The back flutes of the blade are ground to give a smooth surface for polishing. *Filing slot*—The slot is filed to size for the front sight, after which the socket is milled. *Second milling*—This operation rounds the end of the socket next the blade. *Blocking*—The bayonet-clasp is roughly blocked from an iron bar, the cross-section of which is .625 inch by .312 inch, by means of dies and a drop-hammer. *First trimming*—The central portion is punched out, and the fin at the sides trimmed off in a trimming-machine, which consists essentially of a die and punch. *Dropping*—The clasp is reheated, placed on a mandrel and swaged into a die under a drop-hammer. *Second trimming*—The fin around the arch and at the opposite end is trimmed off in a trimming-machine. *Annealing*—A number of clasps are placed in cast-

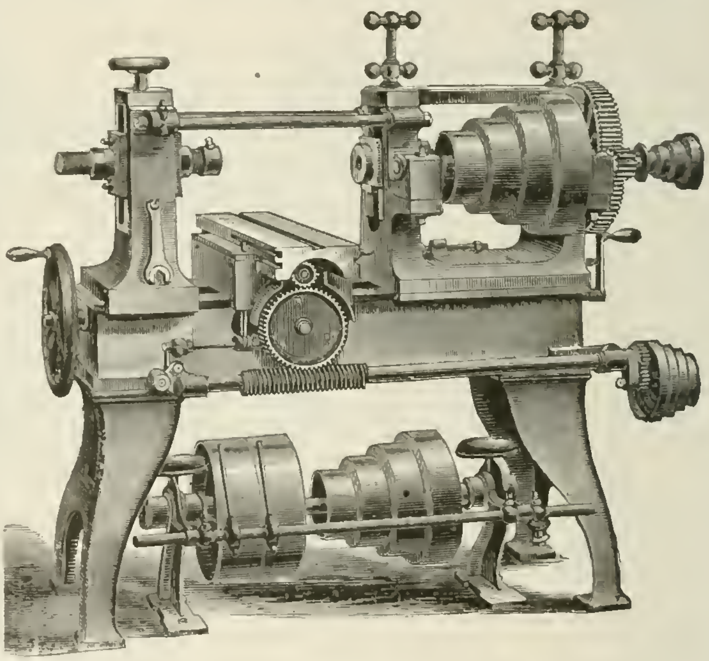

Fig. 3.

iron retorts in alternate layers with fine charcoal, and covers are fastened on with brick-clay. Several retorts are placed in an annealing-furnace, charcoal is packed between and over them, a fire started, and the retorts brought to a red heat. The charcoal having burnt away, the retorts cool gradually, remaining in the furnace about 24 hours. The clasps are then soft enough to be easily turned, milled, etc. They are then vitrioled. *Turning*—The clasp is placed on a mandrel having an arbor or shaft by which the mandrel is held in a turning-lathe. Cutters pressing against each side of the clasp trim off the fin around it left by the die in dropping. *Pressing*—The clasp, again placed on a mandrel, is cold-pressed into shape and thickness to avoid milling the sides.

First cutting—A length amply sufficient for a ramrod is cut from a cast-steel bar, .28 inch round, by a pair of heavy shears. *First straightening*—The piece cut off is straightened on an anvil with a hand-hammer. *First grinding*—The rod is now ground to a uniform size on a grindstone. *First dropping*—One end having been heated, the rod is placed vertically in a clamp-vise and the heated end upset to form a head, by a drop-hammer. *Burring*—The burr formed by the edges of the vise is ground off on a grindstone. *First swaging*—The thickened end of the rod is reheated and the head formed in a die under a pony-hammer, the rod being turned slowly about its longer axis. *Second cutting*—The rod is again cut to a prescribed length, to act as a guide for determining the position of the swell. *Second dropping*—The portion near the head is heated and the rod upset in a clamp-vise, at the proper distance from the head for the swell for the ramrod-stop. *Second swaging*—The form of the swell is determined in a die under a pony-hammer, as explained for the head. *First annealing*—The rod from the head to the swell is brought to a red heat in melted lead and placed in wood-ashes, where it undergoes annealing, after which it is vitrioled. *Second straightening*—The rod is again straightened on an anvil with a hand-hammer. *First milling*—The head and about 3 inches of the body are now milled in a power milling-machine, shown in Fig. 3. The machine has automatic screw-feed, and stop motion adjustable at any point. *Second milling*—The head is next milled to form the flat. *Drilling*—Four small holes are drilled at right angles to the flat to form the slot. *Punching*—The slot is formed by a punching-machine, which easily removes the metal remaining between the holes already drilled. *Sizing*—The head is now brought to size in a clamp-milling machine. *Third milling*—The swell and body for about 2½ inches each side of the swell are milled in a clamp milling-machine. *Fourth milling*—About 4 inches from the swell are now milled to meet the grinding. *Fifth milling*—Same as third milling, except that it extends about 3½ inches each side of the swell. *Filing slot*—The slot is finished by hand-filing, which removes sharp edges left by the punch and rounds the corners. *Second grinding*—The rod is now ground to meet the fifth milling. *Tempering*—The rods, held in a pair of tongs, are placed in a long hollow fire and brought to a cherry-red heat. They are then plunged in a vat of brine, which renders them very hard and brittle. They are next coated with sperm-oil, and heated until the oil is burned off, when they are left with a spring temper. *Third grinding*—They are reground to remove the roughness produced in tempering, and to bring them more nearly to true size. *Sixth milling*—The small end is milled off, so that the rod is of the right length. *Second annealing*—About 4 inches of the small end are annealed precisely as before explained. *Third straightening*—The rod is straightened on an anvil after being annealed. *Seventh milling*—The grooves on the small end are formed in a clamp-milling machine. *First polishing*—The head is polished in a lathe with emery and oil. *Second polishing*—The rod is polished up to the milling, near the swell, in a vertical polishing-machine, in the same manner as explained for the barrel. *Third polishing*—The whole of the portion milled, except the head, is polished on a buff-wheel. The jointed ramrod for the carbine is comprised of three sections of equal length of 8½ inches. The first section has the *stem*, *head*, and *screw*. The second and third sections have the *stem*, *swell*, and *screw*. The swells on the end of these two sections are drilled and tapped to receive the screw-ends of the first and second sections which make the complete rod. The material of which this ramrod is made is cast-steel. *Forging*—The end of the rod, which is round, is upset sufficiently to form the head, and then drawn and rounded under a small tilt-hammer to the proper size and length. *First-straightened*—This is done by hand, while cold, on an anvil. *First-annealed*—Annealed in cast iron retorts by packing in charcoal-dust and heating in a furnace to a cherry-red heat for five or six hours, after which the furnace is allowed to cool slowly. *First-milled*—The first milling is done in a clamp-milling machine, which forms the *head* and *stem* about 3 inches to nearly the right size. *Second-milled*—The rod is then reversed and the remainder of the stem is milled in another set of clamp-milling dies. *Third-milled*—This operation clamp-mills the entire section to its finish-size in dies that receive both the head and stem at one operation. *First buffed*—Buff-polished on a revolving emery-wheel to remove the roughness and prepare it for tempering. *Tempered*—Heated to a cherry red and hardened in water; then it is drawn over a blaze to a spring temper, and second-straightened. *Second-annealed*—The point of the rod is now annealed about half an inch for cutting the thread. *Fourth-milled*—Clamp-mills about half an inch of the end to the proper size for cutting the thread that screws into the other section. *Cut*—The thread is made in the

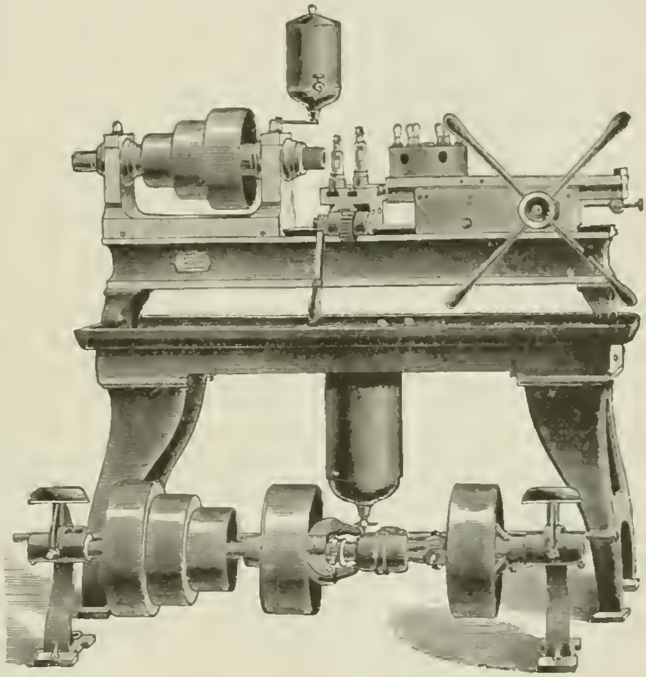

Fig. 4.

screw-cutting machine, shown in Fig. 4. *Second-buffed*—Polishes the head of the rod on an emery-wheel. The drilling and tapping on the second and third sections is done on a screw-milling machine and tapping-machine which drills into the *swell* about half an inch, then taps the hole to receive the screw-end of the other section; the other operations are the same as specified in the first section. The ramrod-stop is formed from a steel rod .57 inch in diameter. One end having been heated is drawn out to give more stock at the ends of the stop in a die under a trip-hammer, after which it is returned to the fire. Four rods are usually worked at the same time. Each one having undergone the above operation, the first one is taken from the fire, transferred to a drop-hammer, and the forging completed by a single blow. It is then *annealed*, *vitrioled*, and *trimmed*.

The following operations are necessary for the mountings and small parts: The *butt-plate* is blocked from a bar by being forced in dies by a single blow from each of two drop-hammers. The fin around the edge is trimmed off by a trimming-machine. The plate is well heated and placed under a drop-hammer which bends it and at the same time swages it into shape in a die. It is then *annealed* and *vitrioled*, after which it is *cold-dropped*, that is, forced while cold in a die by a drop-hammer. *Forging*—The screws are forged from a rod .57 inch in diameter in a die under a pony-hammer. *Annealing*—They are then *annealed* and *vitrioled*. The *rear-sight base* is partially formed from a bar, the cross-section being .562 inch square, in a die under the drop-hammer. *Annealing*—It is next *annealed, vitrioled*, heated and *dropped;* then *annealed, vitrioled*, and *trimmed*. The *rear-sight base-spring* is forged in a die under a drop-hammer from a cast-steel bar .375 inch by .125 inch, after which it is *annealed, vitrioled*, and *trimmed*. The *rear-sight leaf* is partially formed from a bar, the cross-section of which is .438 inch by .50 inch, in a die under a pony-hammer. It is then transferred to a drop-hammer, where the forging is completed by a very heavy blow. It is then *annealed, vitrioled*, and *trimmed*. The *rear-sight slide* is formed from a bar .31 inch square precisely as explained for the rear-sight-base spring. The bar from which the *front sights* are formed is first rolled to bring its cross-section to the form of the cross-section of the sight. A piece of sufficient length for the sight is cut from the bar by a punching-machine, after which the sides and bottom of the pieces are milled nearly to size. Subsequent operations relating to the sight are explained in connection with the barrel. The *guard-plate* is partially brought to form from a rod .57 inch in diameter under a trip-hammer. It is then heated and *dropped, annealed*, and *vitrioled*. The *guard-bow* is blocked from a rod .48 inch in diameter; then *dropped, annealed, vitrioled*, and *trimmed* in the manner explained for the guard-plate. The *guard-bow swivel* is formed from a rod .28 inch in diameter. A portion sufficient for the swivel is drawn out under a pony-hammer, leaving stock at both ends to form the pads, and afterward cut from the rod. The piece having been reheated is placed in a foot-vise and the pads formed by a hand-hammer. It is then *annealed* and *vitrioled*. The *hammer* is made as follows: The heated end of a bar, the cross-section of which is 1.13 inch by .5 inch, undergoes a drawing-out process in a die, under several blows from the drop-hammer. While still hot, the end thus roughly prepared is placed under another drop-hammer and forced in a die by a single blow. It is now returned to the fire. The workman usually has four bars in the fire at the same time, all of which undergo the above operation in succession. The first one is now taken from the fire, the heated end placed under the drop-hammer last used, given a single blow, immediately afterward placed in a trimming-machine, when the fin surrounding is cut off, placed under another drop-hammer and forced into a die by a single blow, which brings the hammer nearly to shape and at the same time cuts it from the bar. The fin or surplus metal forced out by the dies is removed by the trimming-machine. The hammer is reheated and dropped in a die smaller than those used before. It is then *annealed, vitrioled, second-trimmed*, and *cold-pressed*. The cold-pressing is for the purpose of giving a smooth, compact surface, and to save milling the body. In making the *lock-plate*, a flat bar of decarbonized steel, the cross-section of which is 1.75 inch by .22 inch, is *annealed* in charcoal, after which the plate is punched out by a punching-press. The *main-spring* is partially formed in a die under a pony-hammer, from a cast-steel bar, the cross-section of which is .31 inch square. It is then heated and *dropped, annealed*, and *vitrioled*. The *main-spring swivel* is forged from a cast-steel rod, .375 inch by .125 inch, in a die under a drop hammer. It is then *annealed, vitrioled*, and *trimmed*. The *tumbler* is roughly formed from a cast-steel bar, the cross-section being 1 inch by .38 inch, in a die under a trip-hammer. It is next heated and *dropped*, then *vitrioled*. The *bridle* is partially formed from a bar, the cross-section of which is .47 inch square, in a die under a drop-hammer. It is then *trimmed*, heated and *dropped*, and again *trimmed*. The *sear* is formed from a cast-steel rod, .313 inch by .25 inch, precisely as explained for rear-sight base-springs. The *sear-spring* is partially formed from a cast-steel bar, .32 inch by .18 inch, in a die under a drop-hammer. It is then *trimmed* while hot and the forging completed. It is in order *annealed, vitrioled*, and *trimmed*. The *upper band* is formed from a bar, .75 inch by 3.75 inches, in a die under a drop-hammer. The surplus stock (central portion and outside fin) is removed by a trimming-machine. The band is reheated, placed on a mandrel, and forced in a die by a drop-hammer. It is then *annealed* and *vitrioled*. The *lower band* is blocked, trimmed, *dropped, annealed*, and *vitrioled*, precisely as explained for the upper band. It is next

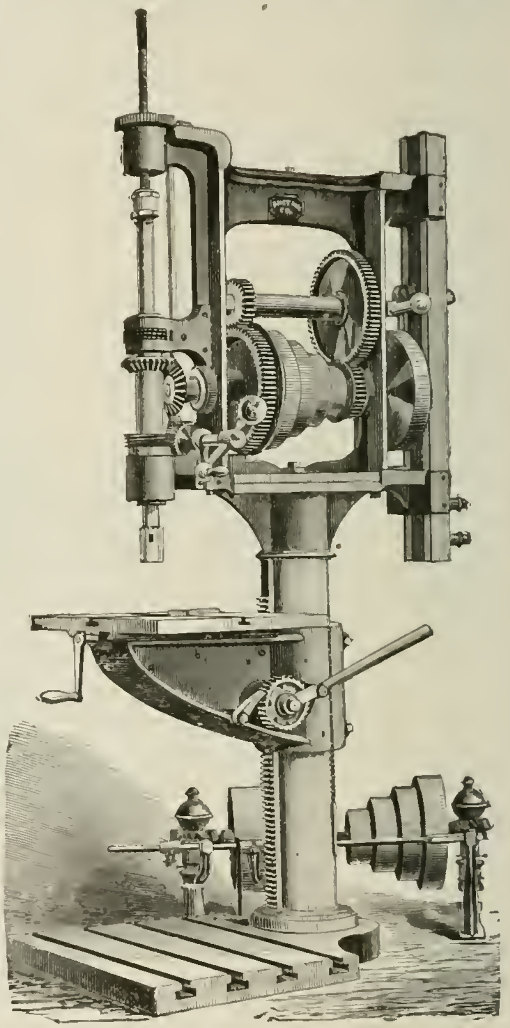

Fig. 5.

placed on a mandrel in a turning-lathe, and the fin at the edges turned off, in the manner explained for the bayonet-clasp. It is then reheated and dropped on a mandrel to bring it to the right thickness, after which it is edged, or the fin at the edges turned off. It is driven while cold on a mandrel-gauge, which serves to give it the required taper. It is also stamped with the letter U. The *band-springs* are formed from a cast-steel rod, .108 inch square, in a die under a drop-hammer. They are then *annealed, vitrioled, trimmed*, and *cold-dropped*. The *side-screws* are forged from a rod, .438 inch diameter, in a die under a pony-hammer. They are then *annealed* and *vitrioled*. The *side-screw wash-*

ers are forged from a bar, the cross-section of which is .313 inch by .563 inch, in a die under a drop-hammer. Eight or ten are forged on a single strip. They are then *annealed* and *vitrioled*. The *breech-screw* is forged from a bar, .75 inch square, one end of which is heated, placed under a drop-hammer and forced in a die by a single blow, which partially forms the screw. The fin around it is removed by a trimming-machine, after which the screw is forced in a slightly smaller die by one blow from another drop-hammer. One heat suffices for the forging. It is then *annealed* and *vitrioled*, after which it is *trimmed* in a trimming-machine; that is, forced while cold through a die by a punch which removes the fin. The *breech-block* is roughly formed from a bar, 1.30 inch by .75 inch, cross-section, by being forced in dies by a single blow from each of two drop-hammers. It is then *vitrioled*, *first-trimmed*, then heated and *dropped*, after which it is *annealed*, *vitrioled*, and *second-trimmed*. The *breech-block cap* is brought to shape in a die by a single blow from a drop-hammer, after which it is *annealed*, *vitrioled*, and *trimmed*. The *thumb-piece* is roughly formed from a bar, 1.31 inch by .38 inch, cross-section, in a die under the drop-hammer. It is then *trimmed* and *vitrioled*, heated and *dropped*, after which it is *annealed*, *vitrioled*, and *second-trimmed*. The *cam-latch* is formed in a die, under a pony-hammer. It is then *dropped*, *annealed*, *vitrioled*, and *trimmed*. The *extractor* is forged from a cast-steel rod, .31 inch square, in a die, under a drop-hammer. It is in order *annealed*, *vitrioled*, and *trimmed*. The *hinge-pins* are partially formed in a die, under a pony-hammer, after which they are transferred to a drop-hammer and the forging completed. They are made from cast-steel rods, .28 inch in diameter. They are in order *annealed*, *vitrioled*, and *trimmed*. The *tang-screws* are forged from a bar .4 inch in diameter; then *annealed* and *vitrioled* in the manner explained for the side-screws. The *receiver* is roughly formed from a bar, the cross-section of which is 1.25 inch square, one end of which having been heated is forced into a die by a single blow of a drop-hammer. It is immediately transferred to another drop-hammer, where it receives one blow, which completes the blocking and cuts the receiver from the bar. It is *trimmed*, then heated and *dropped*, *vitrioled*, *second-trimmed*, and *second-dropped*. Immediately after the *second dropping*, while still hot, the receivers are imbedded in fine charcoal in cast-iron boxes in the same manner as explained for barrels. In about three days they are sufficiently cool to be removed, when they are also soft enough to be easily drilled, milled, etc. They are then *vitrioled* and *third-trimmed*.

From the forging department, the parts are taken to the milling and filing departments, and finally to the assembling department. Many of the parts are subjected to a variety of operations. The object of *drilling* is to form holes for the screws, rivets, etc. Fig. 5 represents a combined drill and slotter, made with a double table and operated two ways, in and out from the column and crosswise at the same time. By this arrangement pieces can be fastened to the table and moved to different positions under the operating spindle without loosening the work from the table. By having drills suited to the operating spindle, this machine can be used for milling irregular forms, such as is usually done in a regular die-sinking machine. The object of the tapping is to convert the surface of the hole into a female screw. This operation is performed by an instrument called the *tap*, which is formed of a piece of steel, of a pyramidal shape, and upon the edges of which are segments of screw-threads. In all operations of cutting and drilling wrought-iron, it is necessary to use oil or water to preserve the temper of the tools. In working cast-iron, no cooling substance is required. The object of *turning* is to give shape and smoothness to the exterior of a body, which is accomplished in the *lathe* (Fig. 2). The body is generally made to revolve around a fixed axis, and a cutter, which has a motion parallel to this axis, is made to press against its surface; the combination of these two motions cuts away a spiral chip, and leaves a new surface concentric with the axis. It will be easily seen that if the cutter has, in addition to its motion parallel to the axis of rotation, another perpendicular to it, the resulting figure will be no longer round, but irregular. This constitutes the principle of *eccentric turning*, and affords the means of turning an almost infinite variety of shapes, simply by regulating the motion of the cutter by a pattern, or model of hardened steel. In this way gun-stocks, and other irregular figures, are formed by machinery; the principle has even been used in copying statuary. Pieces of metal which are not suited to the turning-lathe may be reduced to their proper shape by *milling*, an operation adapted to nearly all surfaces which have right-line elements. It is performed by a revolving cutter, armed with saw-teeth, while the piece to be cut is fastened on a carriage, which moves steadily under the cutter, and along a plane director. See Figs. 1

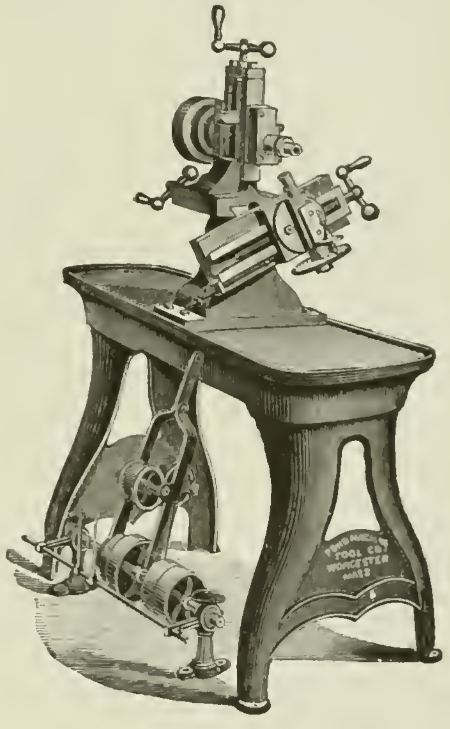

FIG. 6.

and 3; also article MILLING. Fig. 6 represents the index milling-machine, which is applicable to a great variety of light work, such as milling, slabbing, gear-cutting, cutter-making, and profiling. The cross-bar is secured to the foot of the upright, below the horizontal spindle and at a right angle with it, by a large bolt which passes through the upright. The index-spindle, of steel, is mounted vertically in a long bearing on the swivel-plate, which plate is also graduated on its periphery to mark its angle on the cross-bar saddle, to which it is secured by two bolts, and has an index-plate on its lower end, in any one of the holes in which the steel point may be inserted to hold the spindle, while cutting any piece that may be inserted in the tapering hole in the upper end of this spindle, or held in a small vise, chuck or centers on which a suitable hub is cast, bored and provided with screws to secure them to the upper end of the spindle. This machine will cut small gears (to 6 inches diameter) either spur or bevel, or cutters, mill-taps and reamers, straight, taper, or spiral, slab-nuts, slot screw-heads, saw, drill, or profile small parts or fixtures, and steel tools and jigs of all kinds. *Cutting* and *filing* are done by the hand—the former with a cold-chisel, and the latter by a file. They are employed to finish such parts as are not well adapted to machinery. To guide the workman in giving the proper form, the piece is placed in a hardened steel frame, called a *jeg*. *Grinding* is done with rapidly-revolving grindstones, and is principally confined to finishing the bayonet and the exterior of the barrel. *Polishing the surface* of finished parts is done with emery-wheels, which revolve with great rapidity. The wheels are made of wood, and the circumference is covered with buff-leather, to which is glued a coating of emery. *Case-hardening* is the conversion of the surface of wrought-iron into steel, to enable it to receive a polish or bear friction. The process consists in heating the iron to a cherry red, in a close vessel, in contact with carbonaceous matter, and then plunging it into cold water. Old shoes are generally employed for this purpose at the armories, although bones, hoofs, soot, etc., will answer. The materials should be first burnt, and then pulverized. *Hardening* is effected by heating the steel to a cherry red, or until the scales of oxide are loosened on its surface, and plunging it into a liquid, as water, oil, etc., or placing it in contact with some cooling solid; the degree of hardness depends on the heat and the rapidity of cooling. Steel is thus rendered so hard as to resist the hardest file; and it becomes at the same time extremely brittle. In its hardest state steel is too brittle for most purposes; the requisite strength and elasticity are obtained by *tempering*, which is done by heating the hardened steel to a certain degree and plunging it into cold water. The requisite heat is usually ascertained by the color which the surface of the steel presents, due to the film of oxide formed on it:

At 450° Fahr., a pale straw-color.	Suitable for hard instruments, as the faces of hammers, etc.
At 600° Fahr., a grayish blue.	Gives a spring temper, or one that will bend before breaking: suitable for saws, sword-blades, etc.

Shades of colors between these extremes give intermediate degrees of hardness. If steel be heated above 600°, the effect of the hardening process is destroyed. The parts of small-arms are tempered by dipping them in oil, then heating them until the oil is burned off, when they are again plunged into cold water. A blue color is given to the surface of iron or steel parts by heating them till the desired shade appears, when they are removed and allowed to cool gradually, by which the color becomes fast. The barrel and the bayonet, to protect them from the action of the atmosphere and to prevent the surface from reflecting the sunlight, are browned, or covered with a coating of rust. This is accomplished by a mixture of such materials as *tincture of iron*, *spirits of wine*, *nitric acid*, etc., which being applied to the clean surfaces produces a coat which is then well rubbed with a *steel scratch-card* until it has a metallic luster. This operation is repeated till the desired color is obtained. See *Drop-hammer*, *Emery-grinder*, *Milling*, *Rifling*, *Royal Small-arms*, and *Small-arms*.

FABRICATION OF PROJECTILES.—*Shot* and *Shells*, depending upon their kind and size, should be made of gray or of mottled cast-iron, of good quality. Those that are large and required to possess great strength should be of "gun-metal," melted in an air-furnace For ordinary projectiles mottled iron is used; it is obtained by melting, in a cupola-furnace, a mixture of white and gray pig-irons. *Shrapnel* must be made of the best quality of iron, and with peculiar care, in order that they may not be liable to break in the piece. *Grape* and *Canister* should be of soft gray iron, brought to a very fluid state before casting. *Chilled shot* are cast from a special mixture of irons, melted in a cupola-furnace.

All projectiles should be cast in sand and not in iron molds, as those from the latter are seldom uniform in size or shape, are liable to contain cavities, and are cracked if heated. Sand possessing all the properties to be desired for molding is seldom, if ever, found in a state of nature. But, when the requisite qualities are known, the materials may be selected and an artificial composition produced without difficulty. The sand should be silicious, refractory, and of an angular grain of moderate size. The degree to which the first and second qualities should be possessed depends upon the size of the casting; the sand must not be fused or even softened by the heat to which it is subjected. The angular form and large size of the particles increase the resistance of the mold, though rendering it less compact; this last facilitates the

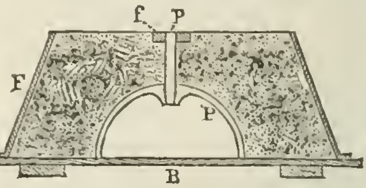

Fig. 1.

evaporation of the moisture in drying, and permits the escape of the gases formed in the material of the mold by the heat of the fused metal. Pit- and not river-sand should be used, as the latter is not sufficiently sharp or cohesive.

The molding composition must contain such an amount of clay that, when slightly moistened, it will retain its shape when pressed in the hand; it must become hard when dried that it may not lose the form given it, and must possess the consistence necessary to resist the pressure of the liquid metal. As clay contracts by heat, an excess of it will cause cracks in the mold in drying. The manner of preparing the composition is usually to mix fire-sand and loam or field-sand, to sift it carefully, and then to moisten it with water in which clay has been stirred. The particular sand to be employed, and the proportion of clay to be introduced, depend upon the size of the casting.

Spherical Projectiles.—Case-shot, shell, and all solid shot smaller than the 15-inch are cast singly. Fifteen- and twenty-inch solid shot are usually cast in clusters of five and three respectively. When cast singly the pattern of a spherical projectile is composed of two hol-

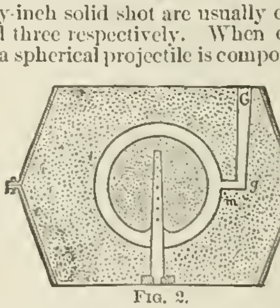

Fig. 2.

low cast-iron hemispheres, uniting in such a manner as to form a perfect sphere; on the interior of each hemisphere is a handle by which it is withdrawn from the sand after molding. The flask has neither top nor bottom, or has movable ones; it is usually in two parts, joining in the same plane as the pieces of the pattern. In molding a *shell* (Figs. 1 and 2), the *pattern*, P, of that half in which is situated the fuse-hole is placed with its flat side upon the *molding-board*, B; this is covered with its corresponding half of the *flask*, F; the *spindle* (*p*), attached to the pattern, passes through a hole in the *cross-piece* (*f*) of the flask. Powdered charcoal or fine dry sand is sprinkled over the board and pattern, to prevent the fresh sand from adhering to these surfaces. The molding-sand is then introduced gradually into the flask being well rammed as it rises up about the pattern. When completed, this portion of the flask with its contents is turned over on a board, the other half of the pattern placed upon that already in position, and the second part of the flask laid on the first and properly fitted thereto. The pattern and the exposed surface of the mold are sprinkled as before, and the molding continued, a conical stick having first been so placed as to form the "*gate*," G, for the introduction of the molten metal. The flask having been filled, the two parts are separated; each now contains one half the mold with the corresponding part of the pattern. The stick for the gate is withdrawn from the outside, and the hemispheres are extracted from the inside. A channel is cut in the plane surface from *g* to *m*, so that the metal, entering at G, may be carried to the mold-cavity at a point where it can flow into place without injury to the surface of the sand. Any imperfections are at this time repaired. The whole interior surface is then coated with a wash of powdered coke and clay-water, after which the mold is thoroughly dried in an oven. This wash gives a smooth, hard surface to the sand, which insures a smooth casting.

The core is formed about a hollow iron spindle, perforated with small holes through which escape the steam and gases generated by the heat of the metal. The core is centered in the mold by means of a gauge, and is supported in that position by the spindle which forms the fuse-hole. The spindle is perforated with small holes to allow the escape of steam and gas generated by the heat of the melted metal; that part of it which forms the fuse-hole is coated with sand to prevent adhesion. When the ears for the shell-hooks are cast in the projectile the necessary projections for their formation are placed in position before drying the mold. In pouring the melted iron into the mold with the ladle, care should be taken to prevent scoria and dirt from entering with it, and for this purpose the surface should be skimmed with a stick of wood. After the iron has become sufficiently hardened the flask is removed, the spruehead is broken off, and the composition scraped from the outside of the casting. The core is then broken up and removed, and the interior surface cleaned by a scraper. The projection at the gate and other excrescences are next chipped off and the surface of the projectile is smoothed in a rolling-barrel, or with a file or chisel if found necessary. The fuse-hole is then reamed out to the proper size and the projectile is ready for inspection.

When shot are cast in clusters, the pattern is made of wood and consists of two longitudinal halves, which are fitted with iron pins or dowels so that they can be accurately joined together for the construction of the mold. The cluster is cast with a sinking-head to feed the shrinkage, while the shot are made with a diameter slightly in excess of the required one, to permit of their being turned down and finished. The flask is also made in two equal parts or sections which are united by bolts. The back of each section is fitted with movable plates, to admit of the introduction of the molding composition. To form the mold, one half of the pattern is laid upon the molding-board, together with the pattern for one half of the channel for the metal, both being held in place by dowels. A section of the flask is then placed in position over the patterns, and the intervening space is filled with molding composition, which is firmly rammed down, the patterns for the branches to the channels being introduced as the work progresses. The plates are then attached in their places. To form the other section of the mold, the finished one is removed from the molding-board and turned over, the remaining halves of the patterns and flask are placed in position upon it, and the molding composition filled in in the same manner. A layer of dry sand is first sprinkled over the surface of the finished section to prevent adhesion. The mold being completed, the two sections are separated and the patterns withdrawn. After being thoroughly dried in an oven and receiving a coating of coke wash on the interior surface, the sections are united and firmly secured together with bolts and nuts. The mold is then ready for the casting and is lowered into the pit. Several clusters are usually cast with one heat of metal, the number depending upon the capacity of the furnace. The casting is usually allowed to remain in the pit for twelve or fifteen hours after the pouring of the metal, when it is hoisted out and taken from the flask. After it becomes cool it is freed from the adhering composition and the gates are broken off.

To separate the shot in the cluster, the latter is placed in a lathe, shown in Fig. 3, the sinking-head being secured in the chuck at the head of the machine, while the other end is supported by a movable center which slides upon the ways. When the cluster is properly centered, the necks which connect the shot are turned down as small as it is safe to make

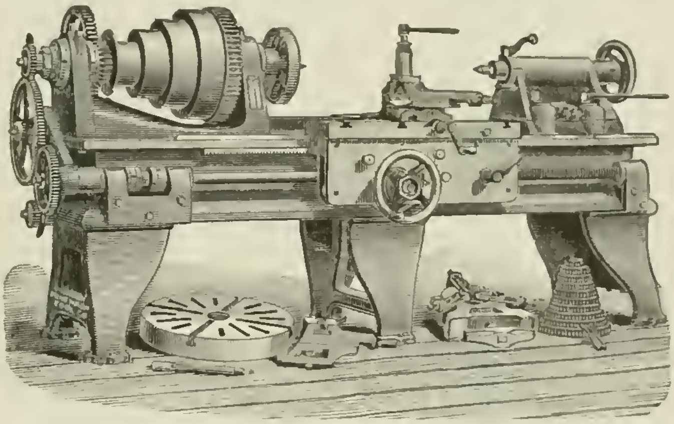

Fig. 3.

them without risking the breaking of the cluster in the lathe. The neck nearest to the bottom is then carefully turned down until it begins to show indications of breaking. The cluster is then chocked up by placing blocks between it and the lathe-bed, the center is slid back, and the shot is broken off by blows with a hammer and removed. The cluster is then recentered in the lathe, and the shot are successively detached in a similar manner until all are separated. Care should be taken to preserve, as far as practicable, a spherical form to that portion of the surface where the neck is turned away. The small portions of the necks which remain after the separation are chipped off by hand. The shot is next turned down to the required diameter and given a smooth and finished surface. The tool-rest of this lathe is attached to a geared wheel, which is pivoted in a horizontal position upon an iron frame secured to the lathe-bed. The motion of this wheel by means of a feed causes the edge of the tool to move on the arc of a circle, its distance from the center of the circle meanwhile being regulated by a screw in the base of the rest. The shot is centered in the lathe by means of a square-headed screw in the axis of the wheel. In turning the shot it is made to revolve upon that diameter which coincides with the axis of the lathe, while the movement of the tool-rest, as above described, brings the tool in contact with all of the surface which is not covered by the supports. In this position the shot is finished as far as practicable, and is then recentered so that the unturned portions of the surface can be brought in contact with the tool, when they are finished in like manner. The ears for the shell-hooks are then drilled in a drilling-machine and the shot is ready for inspection. Fifteen- and twenty-inch shell are sometimes cast above size and finished in the lathe in the same way as cluster-shot.

Elongated Projectiles.—The same principles are followed in the different operations attending the fabrication of elongated as of spherical projectiles. The shape and construction of the flask and pattern depend upon the particular form of the projectile, the system to which it belongs, and the object for which it must be employed. The construction applied in the fabrication of a Parrott shell is shown in Fig. 4; the flask and pattern are each in two parts, united along the plane (*f*, *f*); the *ring* (*m*), of molding-sand, is made in a special box; and is inserted when the mold is assembled before casting, and is necessary to give the shape peculiar to that system of projectiles. The *spindle*, S, as in all the large oblong shells, passes entirely through the *core*, C, and is secured at both ends to the flask, or to the mold. The metal is taken from the cupola into the ladles, and, in the case of chilled shot, usually slightly cooled by throwing in a piece of scrap-iron. This is done to prevent the chill-molds from being cracked. The metal enters the mold from below, near and above the chill-mold, and (from the shape of the lower branch of the "feeder") in an oblique direction, to avoid disturbing the core and to give a circular motion to the metal as it rises in the mold, and so prevent the scoria from adhering to the sides. One workman skims the surface of the metal with a wooden stick, as it runs from the ladle, to prevent the admission of the scoria, while another stirs it as it rises, with an iron rod, through the "riser," to bring the impurities to the surface. Before fairly cooled the flasks are removed, the sand knocked off, the core-stem extracted, and the shot left to cool in the heated sand in which it was cast. The sand is now carefully scraped from the cavity, the sinking-head is removed, and the rough edges trimmed off with a cold-chisel. It is then examined as to quality and weight, and the amount of eccentricity roughly determined. The shot is at once condemned if there be a variation in any of these particulars in excess of that allowed. It sometimes happens, too, that the chill has extended so far over the surface as to make it impossible to finish the shot by the means ordinarily employed in this country. Such shot are, however, sometimes finished by the grindstone. Having passed this preliminary inspection, it is put in the lathe and turned down to the true diameter for the length of .25 inch. The shot is finally passed through the *finishing-press*, and placed in a lathe where the base is finished; if the Butler sabot is to be used, a screw-thread is cut upon the base. The sabot is usually formed of an alloy of 70 parts copper and 30 of zinc. It is either cast separately or directly upon the base of the projectile; in the former case it is bored and turned to the finished size. The shot is completed by tapping a thread on the screw-plug hole, fitting it with a plug, and screwing or casting on the sabot. See *Core-box*, *Finishing-press*, and *Projectiles*.

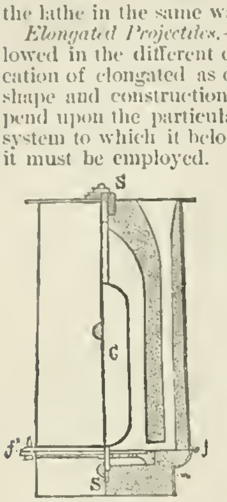

FIG. 4.

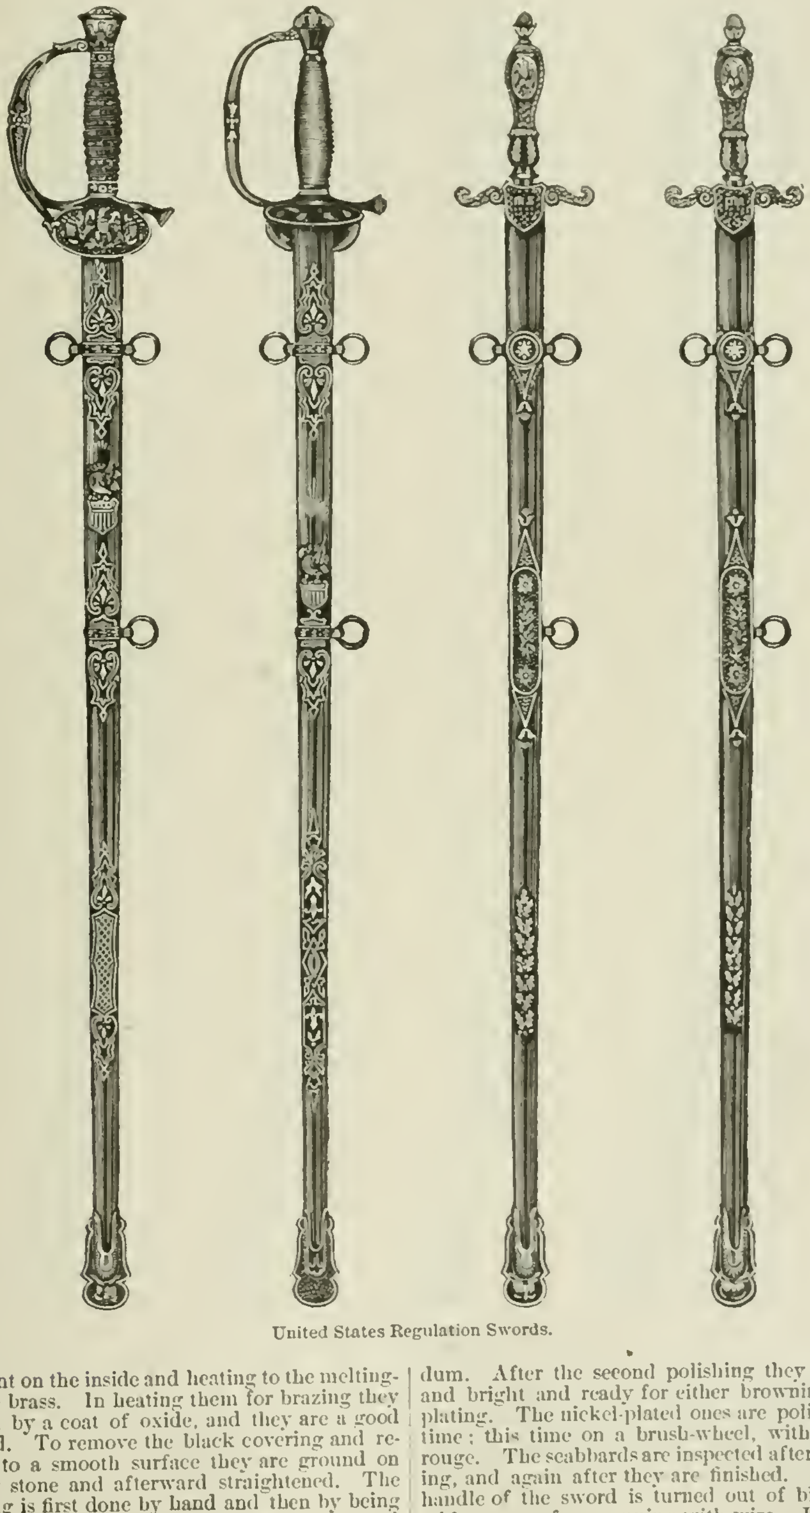
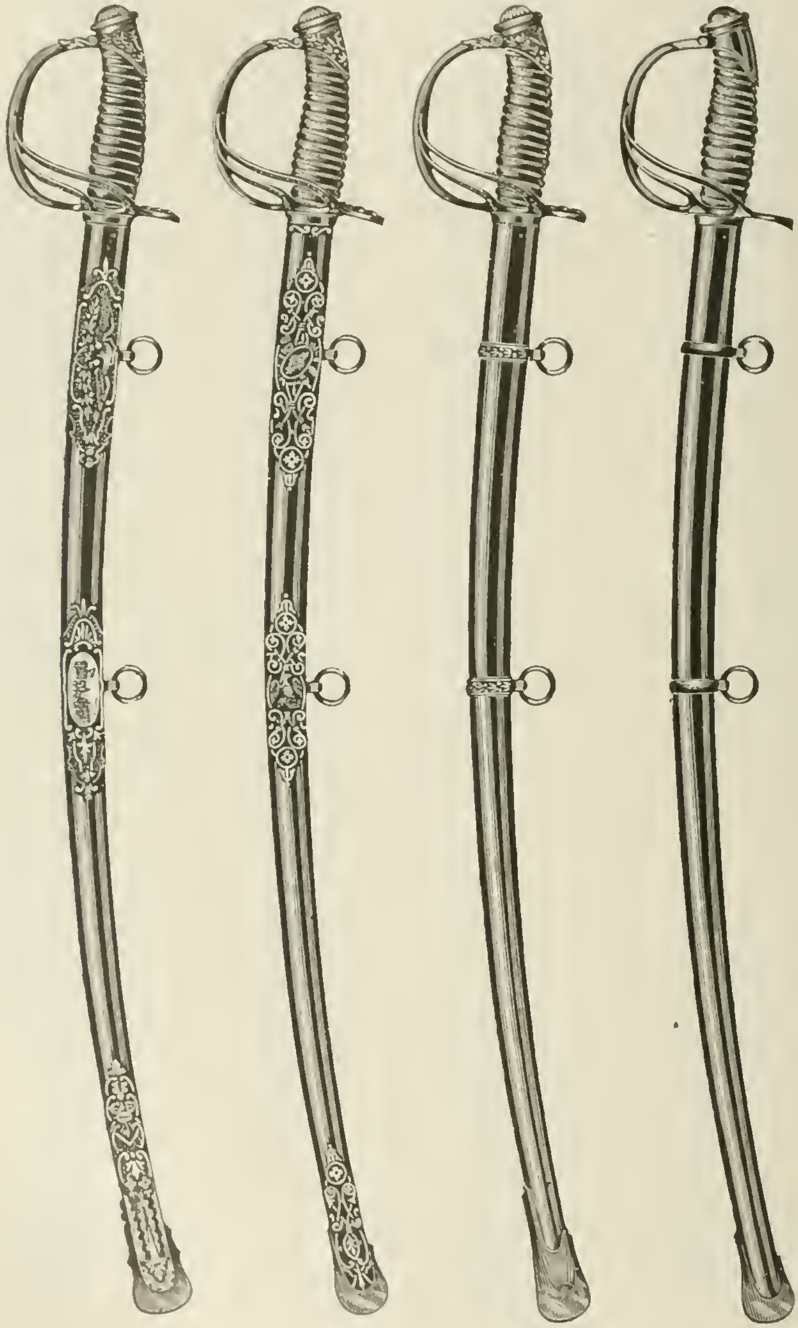
FABRICATION OF SWORDS AND SABERS.—The complete sword consists of the *blade*, *scabbard*, *gripe*, and the *mountings*. The blade is made of the best English cast-steel; the skelp, which is $8\frac{1}{4}$ inches in length, being cut from a square $\frac{5}{8}$-inch bar. The principal operations in making the blade are forging, milling, tempering, grinding, polishing, and etching. The first operation of *forging* consists in drawing out the skelp to nearly the required length of the finished blade, and is done under the tilt-hammer. The second operation, also under the tilt-hammer, draws it out to a little longer than its finished length and shapes it, forming an arris on each side. The *tang*, of wrought-iron, is then welded on, and shaped under a *drop*. After the forging the blade is straightened by hand while cold. To reduce the tang, shoulder, and the portion of the blade immediately adjoining the shoulder to the proper shape and dimensions, they are *milled*. Four different cuts are necessary. At this point the edges of the blade are ground on a revolving stone, to near their required shape, so as to serve as a guide in future grinding operations. The blade is set in a fixture for the purpose. The operation is known as first-edging. The blade after being forged is soft and flexible, and it is necessary to give it a certain degree of hardness and elasticity, which is done by *hardening* and *tempering*. The success of this operation depends greatly on the skill of the workman and his ability to detect by the eye the temperature best suited to the steel used. To harden the blade the workman holds it in the heat of a charcoal-furnace, moving it back and forth to heat the several parts uniformly. When its color is a cherry-red it is withdrawn and plunged into cold salt-water. It is now very hard and brittle, and generally warped. It is therefore necessary to straighten and partially anneal or temper it. To effect this it is again heated; this time to only a blue heat. While thus heated it is soft and can be straightened, which is done quickly, and it is then plunged into cold water as before. This gives it the proper degree of hardness and elasticity. After being tempered the blade is *ground* on rapidly revolving coarse grindstones to reduce all parts to the proper size. Two grindings are necessary: the first extending to the cross-grinding of the whole blade, except the point by which it is held in the fixture; and the second on a finer grindstone, where the point is shaped and the whole blade ground lengthwise. The accurate dimensions are determined by proper gauge. The tang is fitted to a gauge by the file. The final grinding is that of the edges, known as second-edging, by which the edges are reduced to the required accuracy. By grinding, the blade is oftentimes bent and partially annealed. To correct these defects it is again heated to a blue heat, straightened quickly, and plunged into cold water, by which it is retempered. The object of *polishing* is to remove the marks of the grindstone and give it a smoother finish. This operation, done on a buff-wheel with emery or corundum, generally warps the blade, and makes a third straightening necessary. A second lighter polishing prepares it for *etching*—the process of marking the blade with ornamental devices. It is done by first painting the design on the polished blade with any varnish that will resist the action of diluted nitric acid. When this is dry the acid is applied with a woolen swab and attacks the parts of the blade left uncovered, leaving them in a rough or oxidized state, while the design remains smooth and bright. The varnish is dissolved off by spirits of turpentine, and the blade is cleaned with alcohol and whiting.

The *scabbard* is made of sheet-steel, thickness No. 19 Providence wire-gauge. The first operation is that of slitting or cutting the metal into strips of the proper size. These strips are first annealed and bent throughout their length into a gutter shape by means of a simple hand-machine known as a bending-machine. They are still further curved by being placed on a mandrel, clamped in a fixture on the bed of a planer, and passed under a wheel or roller attached to the tool-fixture of the machine. This finishes the shaping of the scabbard, which is elliptical in cross-section. The scabbards being very hard and brittle, to facilitate further operations they are at this point reannealed. The annealing is done by packing them in cast-iron retorts with powdered charcoal and ashes, and subjecting them to a red heat for five or six hours. They are then allowed to cool slowly, which renders them soft and flexible and easily worked. To produce good and accurate surfaces for brazing, the open joint of each is sawed through its entire length and the scabbards are again rolled on the planer. After being tightly wrapped with wire the scabbards are ready for brazing, which is done by placing a piece of brass wire without mandrel. After having the edges sawed up about 1¼ inch from the small end, for the better fitting of the ferrule, the scabbards are polished twice, being straightened after the first or rough polishing. The polishing is done on buff-wheels with emery or corun-



United States Regulation Swords.

over the joint on the inside and heating to the melting-point of the brass. In heating them for brazing they are covered by a coat of oxide, and they are a good deal warped. To remove the black covering and reduce them to a smooth surface they are ground on a revolving stone and afterward straightened. The straightening is first done by hand and then by being rolled on the planer; this time on both edges and dum. After the second polishing they are smooth and bright and ready for either browning or nickel-plating. The nickel-plated ones are polished a third time; this time on a brush-wheel, with crocus and rouge. The scabbards are inspected after each polishing, and again after they are finished. The *gripe* or handle of the sword is turned out of black walnut, with grooves for wrapping with wire. It is covered with shark-skin, glued on and blacked, and is then wrapped tightly with double brass wire. They are bored through from end to end to receive the tang of the blade, and fitted with a ferrule at each end. The *mountings* of hard bronze are made by casting in sand-



United States Regulation Sabers.

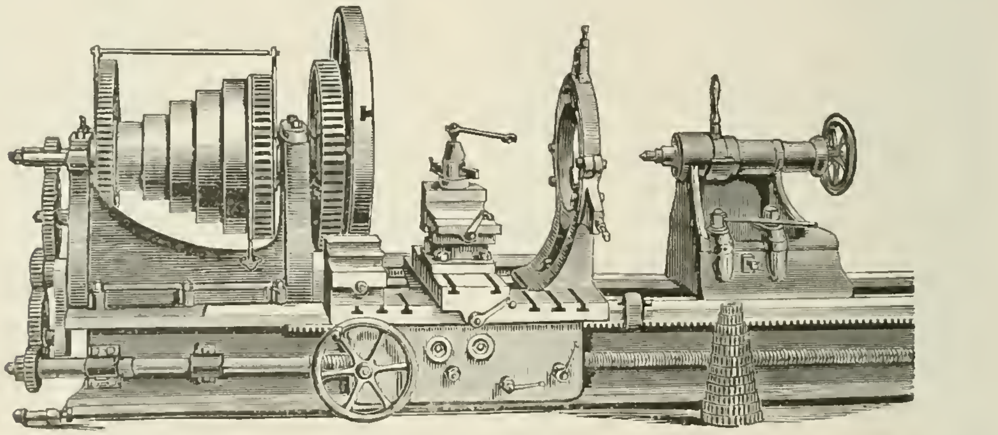
molds. They consist, for the blade, of the guard, crown-piece, and two ferrules for the gripe; and for the scabbard, of the mouth-piece, ferrule, and two bands, with rings for attaching to sword-belt. The guard has on the side next the wearer a hinged shell, held in place by a button and spring. The mountings are fitted in *sets*, gilt and burnished in the armory shops. The different parts being thus prepared, the swords are "assembled;" the mountings being accurately fitted to the blades and scabbards, and the scabbards lined on either flat side with a thin strip of pine, which extends about 15 inches from the mouth. They are finally examined by the Inspector, who selects the blades and scabbards suited to each other. The swords are issued with two scabbards, one browned and one nickel-plated, and are also supplied with chamois-skin cases.

The *bayonet-scabbard* is formed from sheet-steel, thickness No. 19 Providence gauge. The first operation is that of slitting or cutting the metal into strips of trapezoidal shape, 18.75 inches long, 2.53 inches wide at the larger and 1.5 inches wide at the smaller end. The strips are annealed by packing them in cast-iron retorts with powdered charcoal and ashes, and subjecting them to a red heat for 5 or 6 hours, and then allowing them to cool off slowly before exposing them to the air. These strips are first bent throughout their length into a gutter shape by means of a simple hand-machine known as a bending-machine. They are still further curved by being placed on a mandrel, clamped in a fixture or the bed of the planer, and passed under a wheel or roller attached to the tool-fixture of the machine. This finishes the shaping of the scabbard, which is elliptical in cross-section. To produce a good joint for brazing, the scabbard is placed in the planer and a circular saw is passed through its entire length; the scabbard is again rolled on the planer and the edges of the joint are brought into contact; a second annealing is required sometimes, if the steel appears too rigid and stiff to remain in the position bent. The *brazing* is done by first tightly wrapping the scabbard with iron wire to hold the edges of the steel firmly in contact, then placing a piece of brass wire on the inside over the joint and heating to the melting-point for brazing in the flame of a blow-pipe furnace. The operation of *buff-grinding* consists in grinding off the wire and brass which adhere to the scabbard after brazing, and is done on an emery or corundum wheel of the coarsest number. The scabbard is next finish polished, the entire surface, with fine emery or corundum. The operation of *browning* is the same as for rifle-barrels. The scabbard-spring is punched from sheet-steel, No. 19 Providence gauge, in a power-press, to the right length and width. The *curving* is done by heating the springs separately in a hollow oven, which is kept constantly at a red heat; when cherry-red the spring is taken out and replaced by another, with a pair of tongs, and curved in a clamp-vise to the right shape; it is allowed to chill before it is removed from the vise for another. The hole for the rivet is drilled in an upright power-press, the scabbard being held in a suitable fixture. The springs are packed in sheet-iron pans, edgewise, and heated in an oven to a red heat; then plunged into a tank of oil to harden them; then drawn to a spring temper in a sheet-iron pan by applying oil and moving the pan forward and back over the blaze of a charcoal-fire until the oil blazes off entirely, when they are thrown upon a table to cool off. The spring end that rides on the bayonet-blade to hold it is polished to prevent it from scratching the surface of the blade. The spring is *riveted* to the scabbard by hand with a suitable fixture for the purpose. The scabbard and spring are finally inspected: first, to see that the scabbard is properly browned of good body and color; second, to see that the spring is riveted firmly, and that it does not set when a bayonet-blade is inserted into the scabbard, and that the workmanship is good.

The proof and inspection of swords and sabers is conducted as follows: First. The dimensions and form of the blade are verified by comparing it with the model and by applying the appropriate gauges and patterns for the length, width, and thickness at several points, and the curvature, if any. Second. The blade is then proved as follows: 1. The point is confined by a staple, and the blade is bent on each of the flat sides over a cylindrical block, the curvature of which is that of a circle 35 inches diameter, the curvature of the part next the tang being reduced by inserting a wedge .7 inch thick at the head and 14 inches long. 2. It is struck twice on each of the flat sides on a block of oak wood, the curvature of which is the same as the above. 3. It is struck twice on the edge and twice on the back across an oak block 1 foot in diameter. 4. The point is placed on the floor and the blade bent until it describes an arc having the versed sine indicated in the appropriate table. After these trials the blade is examined to see that it is free from flaws, cracks, or all other imperfections, and that it is not *set*—that is, it does not remain bent. 5. See that a piece of iron is welded on the tang for riveting. 6. Observe that the pommel is properly countersunk for riveting tang. The blade of the artillery-sword is proved by striking each of the sides and edges twice on a flat block of hard oak wood. The stamp of approval or condemnation is placed on the side of the blade below the tang. Third. The form, dimensions, and workmanship of the *mountings* are examined and compared with the model. After the blade is mounted the sword is again examined, and it is struck four times on a hard block of wood to test the strength of the mountings. The quality of the brass mountings may be tested by breaking a certain number, not more than four in each hundred, which should be taken from the pieces rejected for erroneous dimensions. Fourth. The form, workmanship, and finish of the scabbards are examined and compared with the model and their fitting to the blades tested. The sewing of leather scabbards and the fastening of the ferrules and tips will be particularly examined. Steel scabbards are proved by letting fall on them from a height of 18 inches an iron weight of 2 pounds, 1 inch square at the base: 1st. On one side just below the upper band; 2d. On the same side 6 inches from the tip; 3d. On the opposite side just above the lower band. In this proof the scabbard should not remain indented. The nature of the material (whether iron or steel) may be tested, if there be any doubt, by using nitric acid, which will leave a black spot on the steel, but not on the iron. See that the mouth of the scabbard is not split or swelled by driving in the mouth-piece. After sheathing the saber, draw it from the scabbard nearly to its full extent, and return it with considerable force three or four times in succession; then examine the riveting of the tang to the hilt. See *Small-arms*.

FABRICATION OF TUBES.—Two plans of conversion of our 10-inch smooth-bore cast-iron guns into 8-inch muzzle-loading rifles, by lining with coiled wrought-iron tubes, find place in our service; one by "muzzle," and the other by "breech" insertion. The parts in general of these converted rifles are: first, the old casing bored out to the exterior diameter of the inserted tube; second, the rifled coiled wrought-iron tube. The mode of manufacturing the iron for the tubes is fully explained in the article COILED TUBES. The A or main tube is composed of four sections or short tubes welded together, each section consisting of two bars, which are united end to end before coiling. The B tube and jacket for tubes, designed to be inserted from the muzzle and from the breech respectively, have now to be made. Their construction, which forms the principal feature of distinction between the two plans of conversion employed, will be subsequently described. The breech-cup is made from a solid forging stamped into shape under the steam-hammer. The collar for securing the tube at the muzzle is made of tube-iron, fagoted and hammered out to the proper size. It is then bent over a mandrel and the ends welded together. The tube and its accompanying parts have now to be transferred to the finishing-shop and prepared for insertion. The power is distributed from the engine by the shafting, which consists of rods of iron running the length of the workshop, and which, by means of attached pulleys, transmit the power used to the different machines. The motion is transferred by means of belts or bands, ordinarily of leather, passing from those above mentioned to similar pulleys. These belts may run direct to the machines themselves, but more usually pass over an intermediate pulley attached to the countershafting; this is placed below the main shafting, and carries pulleys of different sizes, and idle pulleys, by the former of which the rate of speed may be varied, by the latter the machine brought to rest without interfering with the motion of the main shafting. It is frequently necessary to reverse the motion of a machine, and this is effected by using a belt which is crossed between the pulleys over which it passes. While belts are generally employed to transfer rotation from one axle to another where these are at a considerable distance apart, when they are very near each other toothed wheels are used of different form and size, according to the relative positions of the axles and the work the machine is required to perform. When the axles are parallel, spur-wheels are used, in which the teeth project radially from the circumference. When the axles are not parallel, bevel-wheels are employed, in which the teeth are formed on the surface of a cone. Miter-wheels belong to the latter class, and are used when the axles are at right angles, and frequently for simply changing the direction of motion. To enable the various machines to perform the work required of them, the rotary motion of the shafting must be converted into rectilinear and other motion. Circular motion is changed into rectilinear by means of cams. Rectilinear motion is converted into circular by a crank, or by means of a pawl and ratchet-wheel, the pawl being on a jointed arm worked by a cam; the former gives continuous, the latter intermittent motion. The A tube and B tube or jacket are now bored, turned, and otherwise prepared for assembling; the tube turned down for the reinforcing tube and muzzle-collar; the breech-cup turned on the inside and a screw-thread cut on the outside, and the muzzle-collar bored out and a screw-thread cut on the exterior. The gun-casing is also bored to receive the tube, and a recess and screw-thread cut on the muzzle-collar. Much of this work, including that of preparing the sections for welding, is performed in the lathe shown in the drawing. This work requires much power, and, as a consequence, low speed. The power received from the main shafting is first reduced by the countershafting, and afterwards to a different degree by the different steps of the conical pulleys attached to the head-stock. The face-plate is fastened to a mandrel, which passes through the conical pulley and is independent of it. The motion of the conical pulley is transferred in a reduced form to the face-plate by the gearing. When it is desired to give the face-plate the same rate of motion as the conical pulley, the two can be bolted together, and the intermediate gearing thrown out of gear. The cutting-tool is attached at any inclination to a holder, which can be moved by hand on the slide-rest, longitudinally or transversely, by means of the handles shown in the drawing. These motions are made automatic by a connection, through gearing, with the feed-screw. An automatic longitudinal motion is given to the base of the slide-rest by means of the feeding-shaft and worm, while it is moved by hand in the same direction—when thrown out of gear with the feeding-shaft—by means of the pinion gearing into the rack. The leading-screw gives all the required longitudinal motion to the slide-rest in screw-cutting. A series of change-wheels is provided with each lathe, by a suitable combination of which any desired pitch can be given to the thread cut. The back-center can be adjusted by hand to any position, and in many machines an automatic longitudinal motion is also provided by means of gearing in rear, to enable it to carry a boring-rod.

In boring short tubes, such as the sections of the A tube, the cutter is generally passed through a slot in the boring-bar, which passes, in an ordinary lathe, from the head-stock to the back-center. The tube is then attached to a saddle which has a motion of translation, while the cutter has the motion of rotation received from the head-stock. Ordinarily, both in boring and turning, the cutter has the motion of translation, while the tube revolves. In boring or turning cast-iron, it is not usual to use a lubricant. In turning wrought-iron, a mixture of soap and water is allowed to drip upon the tool, which serves to diminish the friction on the tool and preserves its temper. In boring wrought-iron, no lubricant need be used for the rough-cut, but oil must be used during the finishing-cut. Previous to the first turning of any article, the axis must be found so as to center it truly in the lathe. This is simply done in a solid cylinder by finding centers at each end with a pair of compasses; but in the case of a tube a mandrel must be inserted in each end in order that the axis may be actually obtained. After the casing has been bored out to receive the tube, careful measurements are made with the star-gauge for every inch of length of bore. These measurements, plotted on paper, are the workman's guide in so finishing the tube that the play between it and the casing shall not exceed that prescribed. Before shrinking the reinforcing-tube upon the tube proper, both are subjected to the hydraulic test. The apparatus for applying this test consists of two iron cross-heads fitted to the ends of the tube, and which are enabled to sustain the pressure applied through the medium of the connecting rods. Leather washers are used to render the cross-heads water-proof. The water is forced in by a steam-pump through one of the cross-heads, and the degree of the pressure—which must reach 120 pounds to the square inch—is registered by the gauge. The reinforcing-tube is now shrunk on, and the united tubes returned to the bed and finished, and then inserted in the casing. The muzzle-collar is then screwed into place, and the steel securing-pin is inserted through the casing. It is usual to rifle the tube before it is inserted in the casing; but as it is not unfrequently done at this stage of the work, the description of it is here introduced. Only a single groove is cut at a time, and that, ordinarily, as the cutter is going down the bore. All the grooves in a gun are first cut out



Boring and Section Lathe.

roughly and then finished with another cutter. The distance between the grooves is regulated by a disk fixed to the breech of the gun, having its periphery equally divided by as many notches as there are to be grooves. The gun is fixed each time by a pawl, and, when a new groove has to be cut, is turned round to the next notch. Sometimes the periphery is simply subdivided into the required number of equal spaces, while a stationary pointer indicates the position to which the marks on the disk are to be successively brought. The gun is held horizontally in its bed in front of the machine, and remains stationary while the head carrying the cutter moves in and out the bore. Consequently it is necessary to make the bar, to which the head is attached, turn as it advances and returns. Many varieties of machines are used in this country for rifling guns. They differ from each other in the mechanism employed to give this motion of rotation to the cutter. In all of them, the gun-metal head, which carries the cutter, fits the bore accurately by means of burnishers. It is fastened to a stout, hollow iron bar, termed the "rifling-bar." This bar is fixed to a saddle which can be moved backwards and forwards, but is capable of a motion of rotation independent of it. During rifling the metal on the edges of the grooves occasionally becomes burred. The bore must therefore be smoothed, and this is accomplished by a process called "lapping." The operation consists in working backward and forward in the bore a wooden head covered with lead and smeared over with emery-powder and oil. The bore of the gun-casing is also subjected to the same operation before the insertion of the tube. Both the tube and collar now project beyond the muzzle of the casing. They are therefore cut off flush with it, and finished. The hole is tapped for the vent-bushing, which is then screwed into place, and its lower end finished off flush with the surface of the bore. See *Coiled Tubes*, *Converted Guns*, and *Ordnance*.

FACE.—A term of varied application. 1. In fortification, it is an appellation given to several parts of a fortress, as the *face of the bastion*, which is the two sides, reaching from the flanks to the salient angles. The *prolonged* or *extended face* is that part of the line of defense which is terminated by the curtain and the angle of the shoulder. Strictly taken, it is the line of defense *rayant*, diminished by the face of the bastion. 2. In tactics, *to face* is to turn on the heels, as a *right face;* also the word of command for the movement. See *Fortification*.

FACE-COVER.—Engineers since the times of Cormontaigne have mostly adopted his method of placing the top of the scarp-wall on a level with the crest of the glacis, or a little below this crest, to give the wall cover from the assailant's distant batteries. But this is evidently only a partial remedy, since the plunge of projectiles fired from a distance is very great in the descending branch of the trajectory, and with the rifled guns now used these projectiles fired from a distance may pass over the glacis-crest and strike the wall quite low down, thus effecting serious damage, particularly in the case of very wide and shallow ditches.

Various expedients have been proposed by engineers to remedy this defect. Choumara, an engineer of celebrity, has proposed to form what he terms an interior glacis within the ditch, the crest of which shall rise so high above the bottom of the ditch that it shall mask the scarp-wall from the plunge of the distant batteries, and shall force the assailant to establish his breaching-batteries on this interior glacis to enable him to fire low enough to effect a practicable breach in the wall.

Brialmont, a more recent writer, proposes a like plan for the same purposes; and in one of our own works, Fort Warren, Boston Harbor, a heavy earthen face-cover masks a portion of the scarp-wall from a position from which a breaching fire might have been brought against the part thus masked. See *Permanent Fortification*.

FACE OF A PIECE.—In gunnery, the terminating plane perpendicular to the axis of the bore.

FACE OF A PLACE.—In fortification, the front comprehended between the flanked angles of two neighboring bastions, composed of a curtain, two flanks, and two faces. Sometimes called the *tenaille of the place*. See *Fortification*.

FACE-PLATE.—A plate screwed on to the spindle of a lathe, and affording the means of attaching the work to be turned; or the place of attachment for a pin which comes against the *dog* or *driver* on the work and imparts rotation to the latter. See *Lathe*.

FACES OF A SQUARE.—The sides of a battalion or regiment when formed in square.

FACHON.—An Anglo-Norman term for a sword or falchion; but little used. See *Falchion*.

FACING.—1. Powder applied to the face of a mold which receives the metal. The object is to give a fine smooth surface to the casting. The facing consists of various materials, economy and the description of casting being taken into consideration. The following are commonly used: Meal-dust or waste flour, powdered chalk, ashes of wood or tan, charcoal-dust, loam-stone powder, and rotten-stone powder. An equivalent effect is produced by depositing a layer of soot upon a metallic pattern by smoking it in a fire of cork-shavings, or of resin burned in an iron ladle, or in the flame of a link or a lamp. 2. The front covering of a bank by means of a wall or other structure to enable it to be made steeper than the natural talus of the material.

FACING-IMPLEMENTS.—Implements used for facing or renewing the vent and the breech-pieces of an Armstrong or similar gun.

FACINGS.—1. The cuffs and collars of military coats, which are generally of a different color from that of the coats. 2. The movements of soldiers by turning on their heels to the right, left, right-about, left-about, etc.

FACTION.—1. In ancient history, one of the troops or bodies of combatants in the games of the circus, especially of the horse-races. 2. A term applied in an ill sense to any party in a State that offers uncompromising opposition to the measures of the Government, or that endeavors to excite public discontent upon unreasonable grounds. 3. The duty done by a private soldier when he patrols, goes the round, etc., but most especially when he does duty as a sentinel. The French usually say, *entrer en faction*, to come upon duty; *être en faction*, to be upon duty; *sortir de faction*, to come off duty.

FACTIONNAIRE.—A soldier who does every species of detail duty. The term was likewise applicable to the duty done by officers in the old French service.

FAG-END.—The end of any rope. The term is generally applied to the end of a rope when it has become untwisted. *To fag out* means to wear out the end of a rope or a piece of canvas.

FAGOTS.—1. In military history, men hired to muster by officers whose companies were not complete; by which means they cheated the public out of the men's pay, and deprived the country of its regular establishment. 2. Fascines of brushwood, used to revet the interior of batteries, embrasures, etc. See *Fascines*.

FAKING.—Faking is an operation which requires some care. Any person may learn to do it in a kind

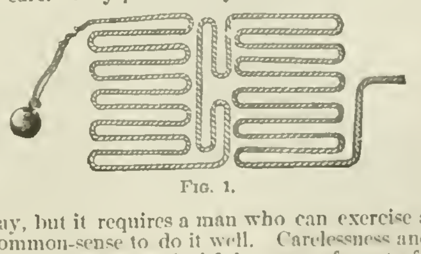


Fig. 1.

of way, but it requires a man who can exercise a little common-sense to do it well. Carelessness and ignorance are the most fruitful causes of want of suc cess in laying up the lines by this method. Practice alone can make a successful "faker." One man *may* fake a line, but having to attend to three operations at the same time, does none of them properly. Two men may put up a line, but, as before, there being more operations than men, they often fail. Three men *can* fake a line well. This work requires a certain degree of care and common-sense. The necessity for thorough instruction and frequent practice is nowhere so urgently called for as in the fitting of men to handle efficiently the appliances for saving human life.

The method shown in Fig. 1 has, after various trials, been found the most practical for laying the rope and placing it into compartments. A particular attention to this mode will never fail with a good

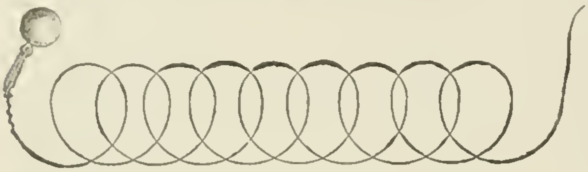

Fig. 2.

rope when the impediments are removed that might otherwise obstruct its rapid flight. Its advantages are that it will allow the eye rapidly (yet correctly, *just before firing*, which is absolutely necessary) to pass over the different compartments, and at once discover if any fake has been displaced by the storm, or by any other casualty or accident come in contact with another part, which would destroy its application by the rope breaking.

It may likewise be coiled in the manner used in the whale-fishery, *whale-lair*, as shown in Fig. 2, and in the method called *chain-faking*, shown in Fig. 3. It is, however, necessary to add that great attention is required in laying it agreeably to the two latter methods, arising not only from the arm being liable to get under certain parts of the rope, and thereby displace it, but from the great anxiety of mind natural on these occasions, where the lives of fellow-creatures are literally dependent on the correctness with which the rope is laid. It is therefore extremely difficult, in a moment of agitation, to determine whether any overlay has taken place, an error that would infallibly destroy every endeavor, and occasion even the fate of those whose lives we might be exerting our-

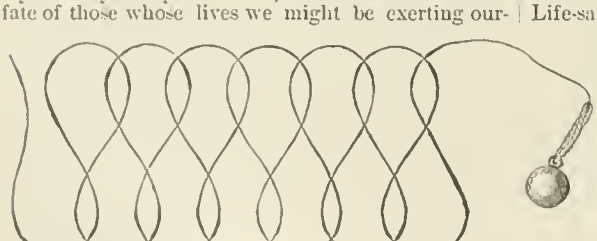

Fig. 3.

selves to preserve. Could persons in the performance of this service be always collected, the two latter methods would have a decided advantage over the first mode of faking, they being laid in a much less space of time. As all these methods of laying the rope occupy time to place it with the care necessary, and as it has repeatedly happened that vessels very soon after grounding have gone to pieces, and all hands perished, it was necessary to produce a method of arranging the rope so that it could be immediately projected as soon as it arrived at the spot; and none proved so effectual as when brought ready in a basket. In this case, the rope should be most carefully laid in alternate tiers or fakes, no part of it overlaying, and it should be well secured down, that in traveling it be not displaced; but above all, no mistake must happen in *placing the basket properly*. For example, that the end of the basket from which the shot hangs in the above figure should be previously marked, and must be placed toward the sea or wreck that the rope be delivered freely and without any chance of entanglement. It will be scarcely necessary to add there will be several tiers of the rope when laid. The utmost care and attention are required in laying the rope in tiers with strict regularity to prevent entanglement. See *Life-saving Rockets*.

FAKING-BOXES.—These boxes are designed for placing the shot-lines in position for firing. The lines are stowed away in the boxes in a peculiar manner, called "faking." The method is one adopted by the English for the stowage of their rocket-lines. In the pattern used in the United States, the sides and ends are dovetailed together at the corners. The top is nailed to the ends and sides with 1¼-inch and sixpenny finishing-nails. The cleats carrying the rope-handles are fastened to the box, one at each end, by four small screws. The "false bottom" has a row of holes, 1.2 inch (3.05 centimeters) in diameter, around the perimeter Along the sides and ends the centers of these holes are situated 1.3 inch (3.3 centimeters) from the edges. The distance between the centers of any two consecutive holes is 2 inches (5.08 centimeters). The sides and ends of the frame for the faking-pins are put together with mortises and tenons. Along the sides, the centers of the screw-holes for the faking-pins are placed 2.5 inches (6.35 centimeters) from the outer edges; the centers of these holes are 3 inches (7.62 centimeters) from the outer edges along the ends of the frame. The distance between the centers of any two consecutive screw-holes in 2 inches (5.08 centimeters). These holes are bored and tapped to form a coarse-threaded female screw. There are seventeen holes on each side and seven at each end of both the bottom and the frame, making forty-eight holes in each. The faking-pins are turned in a lathe from pieces of hickory of the proper length. The body is a frustum of a cone. The upper end is slightly rounded off. A coarse cylindrical screw is cut upon the lower end. A metallic hasp which passes over a button attached to the end of the box is fastened to each end of the frame, and serves to hold the frame and box together in transportation and handling.

The method of fastening in use in the United States Life-saving Service prior to 1879 was simply two staples and a hook. In transportation the hooks were liable to drop out of the engaging-staple on the box and permit the frame carrying the faking-pins and shot-line to fall to the ground and the line to become entangled. While experimenting with life-saving apparatus during the years 1877–'78, Lieutenant D. A. Lyle, Ordnance Department, U. S. A., contrived a metallic hasp and turn-button to replace the old hook and staple. In his report of 1878 he says: "Hasps and turn-buttons were tried on the experimental boxes; these, though safe, sometimes gave trouble in getting ready for the firing when in great haste, and the button being placed on the box, it was thought to give an opportunity for the line when vibrating or whipping to catch and be cut off." In view of these disadvantages, Lieutenant Lyle devised a fastening of three staples, a hasp, ring, safety-chain, and lever snap-hook. The lever snap-hooks are made of malleable iron; the two large staples and hasp of wrought-iron; the small staple, ring, and safety-chain of brass. The whole are tinned, to protect them from rust. The only thing attached to the box is one of the large staples; consequently there is nothing on the faking-box that can interfere with or injure the line so far as the fastening is concerned. The other parts are all attached to the "frame," and are removed with it when preparing for firing.

The operation of the lever-snap is very simple. The mere act of hooking the snap in the staple compresses the spring, raises the bent end of the lever, allows the staple to pass within the hook when the elastic force of the spring closes the snap, and locks it. To remove the hook from the staple, seize the looped end with the thumb and index-finger, and press them together. This action will depress the end of the lever on the opposite side of the fulcrum from the hook and unlock the snap so that it can be withdrawn from the staple. These lock-snaps were intended for the use of harness-makers, and hence the lengthened slot at the end opposite the hook—which was made for the attachment of a strap or rein of a given width. This length of slot is unnecessary as regards the convenience of fastening the safety-chain and snap-hook together, but serves a most useful purpose in the Life-saving Service. The excess of length of slot necessitates a corresponding amplitude of the rear end of the hook, and allows a much wider cavity for the play of the rear end of the bent lever. It also admits of this end of the lever being made spatula-shaped. The size of the cavity and end of lever are such that the snap may be unlocked with ease by the surfman, no matter how large his thumb may be or how thick the gloves or mittens that he is wearing. This is a point of great importance, as the surfmen can manipulate this portion of the apparatus in the coldest weather without removing their hand-coverings.

The German faking-boxes are very similar to those in use in the United States. They differ from the American box in being longer, a little less in width, and far more complicated in construction. The top of the box has three equidistant transverse cleats on the upper side to strengthen it. A lip at each end overhangs the end of the box. Iron straps attached to the lid and run inside of the box form the hinges. These hinges are held in position and swing upon iron pins 5.875 inches in length, having an eye at one end and a slot at the other. A leather thong is made fast in the eye-hole, and is long enough to pass through the slot in the other end of the pin. This pin is thrust through the cylindrical heads of the hinge-straps on the box and lid, and the thong is passed through the slot to secure the pin in position. This arrangement admits of the top or lid being removed entirely when desired. Two slotted straps or hasps attached to the front side of the lid engage the staples on the front of the box. The body of the box is rectangular in shape, open at the top and bottom, and of sufficient depth to contain the faking-pins and line.

It has been found that the term of service of a wooden faking-box is very short. The vibrations of the line, when the full charge of powder is used, are so violent that the ends of the box are often split, and sometimes the sides and top. It was for the purpose of preventing this splitting that angle-pieces of cast-brass were placed upon the four corners. Though this method of construction has remedied the defect to a certain extent, it has not fully obviated it. To secure the necessary lightness of the box, it was requisite that it be made of light wood, and that the material be very thin; consequently the box is quite fragile. If a material can be obtained that will possess a greater degree of durability than one made of wood, and weigh no more than the latter, that material should be adopted, provided the cost of manufacture be reasonable. See *Faking* and *Life-saving Rockets*.

FAKIR.—A word derived from the Arabic *fakhar* (poor), and designating a member of an order of mendicants or penitents, chiefly in India and the neighboring countries. In Persia and Turkey the word is also used for Moslem priests and dervishes. The origin of fakirism, an institution which reaches back to the most remote antiquity, is lost in mythical darkness. The common account of the son of a mighty Rajah, who, expelled from his home and country by the cruelty of his father, made a vow, half in revenge and half in contrition, henceforth to roam a beggar through the world, and to win proselytes to a life of poverty and self-mortification, as the one most befitting in man and most pleasing to the Deity, can hardly be called historical. The same yearning for rest, for peace and pious contemplation, for escape from the noise and turbulence of the world, which has everywhere and always led still and pensive minds into seclusion and solitude, must naturally have been more powerful here, in a land which yielded almost of itself, and in abundance, all that was necessary for the sustenance of man—in a climate of flower and sunshine, where a hermit's calm retreat might well rise before the wearied eye in all the soft sunset hues which surround the abode of the recluse in the Ramayana or in the Sakoontala. But constant seclusion and ceaseless meditation here, as elsewhere, produced in all but exceptional minds their sad results. Piety is no longer enough; sanctity is the goal. Thus, abstinence becomes mortification and a self-torture; mental repose, mystic self-absorption or frenzied exaltation. This leaning of the Hindus to a life of asceticism was fostered by their primeval religion, which enjoins various exercises of penance and mortification upon the three higher castes in general, but upon the Brahmins in particular. These, having passed through different stages of regeneration, end by becoming Sanyassis ("who have left everything") and are dead to the law. The world and its usages have no more any claim upon them; even religious ceremonies are no longer necessary to the "united with God." They go naked or in filthy rags, receive the meanest food only, and that without either a demand or thanks. Their ethical code consists in the observance of truth, chastity, internal purity, constant repentance, and contemplation of Deity. After these models fakirism seems chiefly to have been framed, and its adherents were not only pious men, but occasionally saints, workers of miracles, and healers of all ills, especially epilepsy and sterility. The halo which from the first surrounded fakirism, and the ready worship offered by the people, attracted to its ranks, at a very early date, many whose motives were anything but pure, and who, under a garb of humility and mendicity, collected fabulous treasures. Strabo already distinguishes these vagabonds from the more honest members of their class, and if we may trust the travelers of our own day, the more respectable element has now altogether disappeared. Their number is variously stated. In the time of Tavernier's visit there were more than 1,200,000 Hindu and 800,000 Mohammedan Fakirs in the East Indies, and their present number is said to exceed 3,000,000. Papi describes the Mohammedans as guilty of the greater follies. At times, especially in their return from distant pilgrimages, they are even dangerous, as the killing of an unbeliever is supposed to be an infallible introduction to the glories of paradise. They live either separately as hermits or solitary mendicants, or unite in large gangs, carrying arms and a banner, beating drums, and sounding horns as they approach a town or village. Their appearance is disgusting in the extreme; they go naked, besmeared with the dung of the holy animal, the cow. Some bedeck themselves with the skins of serpents, some with human bones; others array themselves in the garb of women. Their fearful shrieks, and the hideous rollings of their eyes, add to the disgust of their appearance. Imitating madmen, they generally end by becoming madmen. The height to which self-torture is frequently carried by these wretched fanatics, and of which we meet with signs even so far back as the Ramayana, where a penitent is described as perpetually sitting with upraised arms between four fires, the sun forming the fifth, is so appalling that human nature shrinks from the mere description. Some pass their whole lives in iron cages, laden with heavy chains; some clinch their fists till their nails grow through the hand; others hold aloft both their arms till they become like withered branches; while others, again, tie their hands and feet together, and roll head over heels for thousands of miles. Not the least sad feature in all this is that these religious antics are not confined to men, but that youths, and even children of tender age, are initiated therein.

FALARIQUE.—Combustible darts or arrows of various thicknesses, generally about 3 feet long; close behind the head was lodged the combustible matter, by which shipping, etc., was set on fire. The falarique was projected from a bow or catapult.

FALCAIR.—A soldier who was armed with a *falcarius*, or short crooked sword.

FALCHION.—A peculiarly shaped broad-bladed sword, added to the offensive weapons used in the reign of Edward I., 1272–1307.

FALCON-BEAKED.—A term applied to battle-axes and the like when large and curved.

FALCONET.—A name used in the fifteenth and sixteenth centuries for the smallest class of cannon. The ball weighed from 1 lb. to 3 lbs., and the gun from 5 cwt. to 15 cwt.

FALL.—1. In artillery material, the name given to any rope which is passed through blocks, so as to form part of a tackle. The rope attached to a gin, which passes over a double and triple block, the end of it passing round the windlass, is termed the *fall*. The fall for this purpose is generally made of strong rope, depending on the weight to be lifted.—2. The surrender or capture of a place after it has been besieged.—3. The descent of a body by the attraction of the earth.

FALL FOUL.—An expression used in the military sense of making an attack or assaulting.

FALL IN.—The word of command for soldiers to form in ranks, as in parade, line, division, etc.

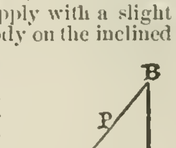
FALLING BODIES.—Owing to gravity, all terrestrial bodies, if unsupported, *fall*, or move towards the earth's center. When a falling body is absolutely without support, it is said to fall freely, as distinguished from one descending an inclined plane or curved surface. We shall here consider the two cases of free descent and of descent on inclined planes.

1. *Bodies falling freely.*—The first fact of observation regarding falling bodies is that they fall with a variable velocity; from this we infer that they are acted upon by some force. Again, on observing how the velocity varies, we find that its increments in equal times are equal; from this we conclude that gravity is a uniform force, which it is, at least sensibly, for small distances above the earth's surface. We have next to find a measure for this force. By experiment it is found that a body in 1 second falls through 16.1 feet, and that at the end of 1 second it moves with such a velocity, that if it continued to move uniformly after the 1 second expired, it would pass over 32.2 feet in the next second. Hence 32.2 feet is the measure of the velocity which has been generated in 1 second, and is therefore the measure of the accelerating force of gravity; for the measure of accelerating force is the velocity which it will produce in a body in a second of time. The quantity 32.2 feet is usually denoted by the letter g; and it is proper to mention here that this quantity measures the accelerating force of the earth's attraction on all bodies. Experiment shows that under the exhausted receiver of an air-pump all bodies fall with equal rapidity, and that the difference of velocities of falling bodies in air is due entirely to the action of air upon them. As the accelerating force is uniform, it follows that the velocity generated in any time, t, will be given by the formula $v = gt$. Since the force is uniform, it must generate an equal velocity every second. In t seconds, therefore, it must generate a velocity gt, since it produces g in 1 second. In 2 seconds, a falling body will be moving with a velocity of 64.4 feet—i.e., were the velocity to become constant for the third second, it would in that second move through 64.4 feet. We are now in a position to inquire more particularly how bodies fall, and to answer such questions as—First: What time will a body falling freely take to fall through a given space? Second: What velocity will it gain in falling through a given space? Third: How high will a body ascend when projected straight up with a given velocity? etc. Let A be the point from which a body falls, and B its position at the end of the time t; and let AB = S. Then we know that at B the body has the velocity gt. Suppose, now, the body to be projected upwards from B towards A with this velocity gt—gravity acting against it, and tending to retard its motion. We know that at the end of a time t it will be again at A, having exactly retraced its course, and lost all the velocity with which it started from B, because gravity will just take the same time to destroy the velocity gt which it took to produce it. From this consideration we may obtain an expression for the space AB or S in terms of the time t. In the time t, the body rising from B with a velocity $= gt$ would ascend, if not retarded, a height $(gt) \cdot t$, or gt^2. But in the time t, gravity, we know, carried it through S; it will therefore, in the same time, by retarding it, prevent it going to the height gt^2 by a space = S. The space through which it actually ascends is then represented by the difference $gt^2 - S$; but this space we know to be AB or S. Therefore $S = gt^2 - S$; or $2S = gt^2$, or $S = \frac{1}{2}gt^2$. We may give this equation another form. For v being the velocity acquired in the time t, $v = gt$, $\therefore t = \frac{v}{g}$. Then $S = \frac{1}{2}g \cdot \frac{v^2}{g^2} = \frac{v^2}{2g}$. Hence $v^2 = 2gS$. From these formulæ we see that when a body falls from rest under the action of gravity, its velocity at any time varies as the time, and the square of its velocity as the space described. If the body, instead of starting from rest, has an initial velocity V; and if v, as before, be the velocity at the time t, then evidently v is = the original velocity + that which is generated by gravity, or $v = V + gt$; and the space will be that which would have been described by the body moving uniformly with a velocity V + that which it would describe under gravity alone, or $S = Vt + \frac{gt^2}{2}$. With regard to the last two formulæ, it is easy to see that they may be made to suit the case of a body projected upwards with a velocity V, by a change of signs; thus $v = V - gt$, and $S = Vt - \frac{gt^2}{2}$; gravity here acting to destroy velocity and diminish the height attained. From the general formulæ in the case of an initial velocity, whether the body be projected upwards or downwards, we may express v in terms of S, as we did in the case of motion from rest. For

$$v^2 = (V \pm gt)^2 = V^2 \pm 2g\left(Vt + \frac{gt^2}{2}\right) = V^2 \pm 2gS.$$

These are all the formulæ applicable to the case of falling bodies, and by their means all problems in this branch of dynamics may be solved. It also appears that the formulæ above investigated apply to all cases of rectilinear motion of bodies considered as particles under the action of any uniform force. In all such cases, if f measure the accelerating force $S = \frac{1}{2}ft^2$, $v^2 = 2fS$, for the case of motion from rest; and $S = Vt \pm \frac{1}{2}ft^2$, and $v^2 = V^2 \pm 2fS$, for the case of an initial velocity.

2. *Bodies descending inclined planes.*—In this case the formulæ already investigated apply with a slight change. In the figure, if P be a body on the inclined plane AB, descending under gravity, we observe that only that resolved part of gravity parallel to AB is effective to make it descend, the other part at right angles to AB merely producing pressure on the plane. The angle of inclination of the plane being α, we know that the resolved part of gravity parallel to the plane is $g \sin \alpha$. The body, then, may be conceived to be descending under a uniform accelerating force $g \sin \alpha$. We obtain the formulæ, ac-



cordingly, for descent on inclined planes by substituting $g \sin a$ for f in the general formulæ given above. We notice, however, that in descent on inclined planes the velocity acquired is, as in the case of bodies falling freely, due solely to the vertical height through which the body falls. By our formula, $v^2 = 2g \sin a$. S, where S = AB, if the body falls from B. This may be written $v^2 = 2g$. S . $\sin a$, or $= 2g$. AB . $\sin a$, or $= 2g$. BC, since AB . $\sin a$ = BC. But this is the same as the velocity acquired by a body in falling freely through BC. In fact, it holds generally true that the velocity acquired by a body falling down the surface of any smooth curve is that due to the vertical height through which it has fallen; which might be proved in various ways, but is sufficiently clear from this, that any curve may be considered as a succession of inclined planes, indefinitely short in length and great in number; for the proposition being true, as above proved, for each of them, will be true for all, and therefore for the curve. See *Atwood's Machine*, *Parallelogram of Forces*, and *Projectiles*.

FALLING BRANCH.—That part of the trajectory of a projectile in which it approaches the earth. See *Trajectory*.

FALL OUT.—To quit the rank or file in which one is first posted. Untidy soldiers on parade are frequently ordered to *fall out*, and remain in the rear of their companies. The phrase is applicable in a great variety of instances.

FALOIS SYSTEM OF FORTIFICATION.—The front of this system consists of two enceintes of equal command, so that the inner one is well covered. The bastions contain cavaliers which may readily be transformed into retrenchments. The second enceinte consists of counterguards and ravelins connected by batardeaux. A low battery forms the reduit of ravelin. The ravelin, its reduit, and the counterguard are casemated for artillery. The covered-way is replaced by a system of crémaillères, which possess the great defect of furnishing the besieger with a parallel ready made.

FALOTS.—Small lanterns fixed upon the end of a stick or pole. Small lamps likewise used, attached in the same manner, for the purpose of carrying them readily about to light a camp, or besieged towns, as occasion may require.

FALSE ALARMS.—Stratagems of war frequently made use of to harass an enemy by keeping him perpetually under arms. A vigilant officer will occasionally make a false alarm to learn if his guard is on the alert. A fearful or negligent sentinel will create alarm by false reports.

FALSE ATTACK.—An approach which is made as a feint for the purpose of diverting an enemy from the real object of attack. False attacks should be carried out on several points of the works to be attacked, and at the same time as the real one is going on. The strength of the force detailed for this duty should be imposing. See *Feint*.

FALSE FIRES.—Lights or fires employed for the purpose of deceiving an enemy. When an army is about to retire from a position, during the night false fires are lighted in different parts of the encampment to impose upon the enemy's vigilance.

FALSE FRAMES.—When the soil is very bad, the miners make use of these frames. They are of the usual height, but narrower, and exactly of a width from outside to outside, equal to the width in the clear of the ordinary frames.

FALSE IMPRISONMENT.—Every confinement of the person is an imprisonment, whether it be in a common prison or a private house, or in the stocks, or even by forcibly detaining one in the public streets. A man is liable for detaining the person of another, not only without cause, but without legal cause. Thus, where a man gives another in charge for committing an offense, the former is liable to an action for false imprisonment if he fails to substantiate his cause. Police-officers, also, are liable for apprehending a man without a competent warrant, or without reasonable suspicion. But where a felony has been committed, an Officer is entitled to arrest on suspicion. Not only Constables but private persons may arrest a man who commits a felony in their presence. A person who has falsely imprisoned another is liable to a criminal prosecution, and also to a civil action. In the former case he may be punished by fine and imprisonment; in the latter, he must pay such damages as are awarded. Any one detained without sufficient cause is entitled to apply for a writ of *habeas corpus* to procure his liberation. In Scotland this species of offense is called Wrongous Imprisonment.

FALSE LIGHTS.—In debarkations under cover of the night, lights may be used as signals of deception, when it is found expedient to attract the attention of the invaded country towards one part of the coast or territory, whilst a real attack is meditated against another. See *False Fires*.

FALSE MUSTER.—An incorrect statement of the number of effective soldiers and horses. Any officer who knowingly makes a false muster of man or horse, or who signs, or directs, or allows the signing of any muster-roll, knowing the same to contain a false muster, shall, upon proof thereof by two witnesses, before a Court-Martial, be dismissed from the service, and shall thereby be disabled to hold any office or employment in the service of the United States.

FALSE RETURN.—A willful report of the actual state of a brigade, regiment, troop, or company, by which the Commander-in-Chief of the War Department is deceived as to the effective force of such regiment or company. Every officer who knowingly makes a false return to the Department of War, or to any of his Superior Officers, authorized to call for such returns, of the state of the regiment, troop, or company, or garrison under his command; or of the arms, ammunition, clothing, or other stores thereunto belonging, shall, on conviction thereof before a Court-Martial, be cashiered. See *False Muster*.

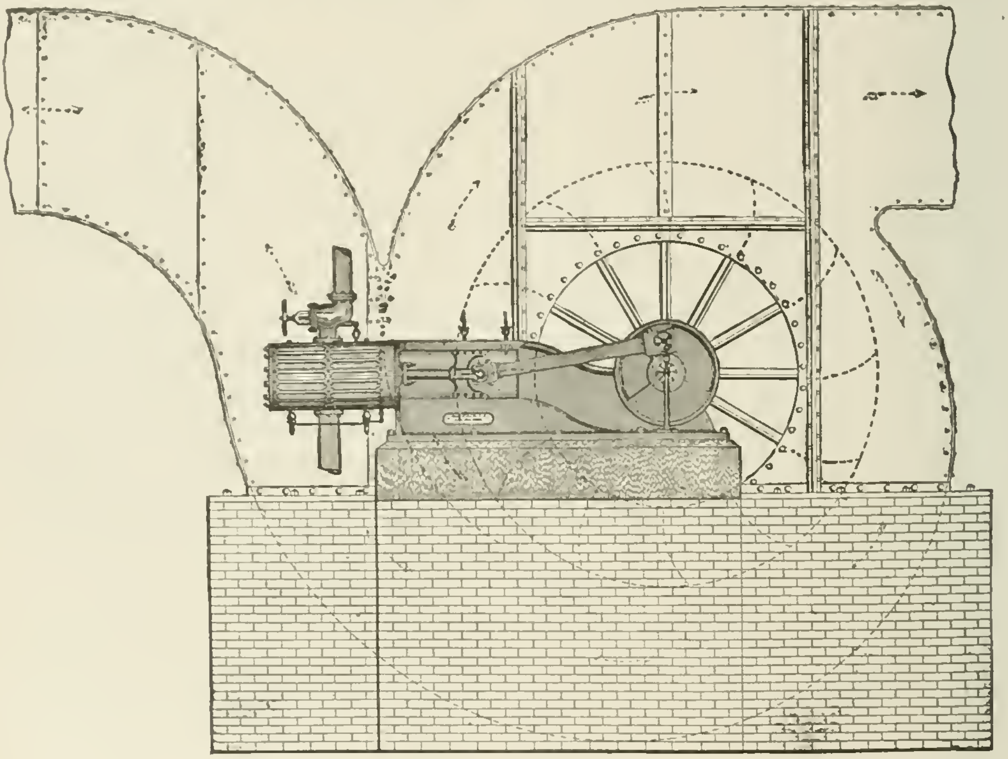
FANARIOTS.—The general name given to the Greeks inhabiting the Fanar or Fanal in Constantinople, a quarter of the city which takes its name from the beacon (*phanarion*) situated in it. They first appear in history after the taking of Constantinople by the Turks, and appear to have been originally descendants of such noble Byzantine families as escaped the fury of the barbarians. Afterwards, however, the class was recruited by emigrants from different parts of the old Byzantine Empire. Subtle, insinuating, intriguing, they soon took advantage of the ignorance of the Turkish Governors, and made themselves politically indispensable to their Rulers. They filled the offices of dragomans, secretaries, bankers, etc. One of them, named Panayotaki, at a later period, was appointed Dragoman to the Divan, and his successors obtained still greater honors. Through their influence the lucrative office of Dragoman of the Fleet was called into existence, which gave them almost unlimited power in the Islands of the Archipelago. Besides, from them were chosen, until the outbreak of the Revolution in 1822, the Hospodars of Wallachia and Moldavia, while, in addition, the disposal of most of the civil and military posts under the Turkish Government was in their hands. In spite of their power, however, the Fanariots never exhibited much patriotism; they were animated by the petty motives of a caste, and when the War of Liberation broke out among their countrymen, they took no part in it. In the present altered state of affairs in Turkey, they have no political influence.

FANFARE.—The French name of a short and lively military air or call, executed on brass instruments. It was brought by the Arabs into Spain, whence it passed into Mexico and the New World. *Fanfaron*, derived from fanfare, is the name given to a swaggering bully or cowardly boaster, probably because of the empty noise he makes when "blowing his own trumpet," or threatening timid people, and the term applied to his idle braggadocio and vaporing vaunts is *fanfaronnade*.

FANION.—A small flag which was sometimes carried at the head of the baggage of a brigade. It was made of serge, and resembled in color the uniform-livery of the Brigadier, or of the Commandant of any particular Corps.

FANNER.—A machine of great value for producing currents of air and creating blasts to melt pig-iron in foundries. It is much used in the ventilation of hospitals, armories, ships, and mines. For the last it is now considered preferable to the plan of furnace-ventilation, especially where there are fiery seams of coal. In its construction the fanner is like a wheel, having the arms tipped with vanes, instead of being joined by a rim. It is placed inside a chest—usually in an eccentric position—with openings on each side round the spindle for the admission of air. The motion is given by steam or other power; and as it revolves, the centrifugal action sucks in air at the center, largely augments the working pressure. In Platt and Schiele's silent fanner the air enters by a central entrance at one side only, and is expelled from the case at the opposite side. The vanes have a peculiar shape, and describe what the inventor (Schiele) calls an anti-friction curve. It is said to be very efficient, and so also is another form of noiseless fanner manufactured by Mr. George Lloyd, London.

The drawing shows a form of Sturtevant's exhausting fanner especially adapted for use in any place where the blower can be placed in the basement, and the air be used for the ventilation of rooms above. In such cases it can be used as an exhauster by closing up the inlet on engine side and connecting a pipe or duct to the opposite side, bringing the air from any distant point where it can be had fresh and pure. This manner of discharge is also most convenient and desirable when used for exhausting foul air, gases, smoke, etc.,



Sturtevant Exhausting Fanner.

draws it towards the tips of the vanes, and these impel it forward through the exit-pipe. Engineers differ as to the proportions which should be adopted for the fanner, and as to the extent of spiral which the fan-case should have. For foundries and smithies, where the pressure of the blast required is from four to five ounces per square inch, the following have been found to suit very well in practice: the width of the vanes, as well as their length, made one fourth of the diameter of the fanner; the inlet openings in the sides of the fan-chest one half, and the degree of eccentricity one tenth, of this diameter. There is a segmental slide by which the opening into the delivery-pipe may be increased or diminished. For such purposes fanners vary from three to six feet in diameter, and they are entirely constructed of iron. Double fanners have been introduced by Mr. Chaplin in England, by M. Perrigault in France, and by Mr. Sturtevant in America. In these, two simple fanners are so disposed on one spindle that the blast produced by one passes in its compressed state through a tube to the other, which from mines, tunnels, or other underground apartments, and it is desired to discharge it upward, out of the way of workmen, or above the tops of buildings. One of the happiest applications of the fanner has been to draw off and render harmless the shavings from planing-machines and the fine steel-dust in the operation of needle-grinding. It should be remembered that small, long branch-pipes with large openings for air around the revolving cutters, or between them and the hoods, cannot be made to work unless the exhauster is driven at a very high speed. Large pipes and close-fitting hoods around the cutters, fitting so closely that there will be no unnecessary opening for the air, will enable the exhauster to do its work with less number of revolutions. The velocity of the air entering the hood around the cutters should be about the same as the velocity with which the outside of the blast wheel travels, say one hundred to one hundred and fifty feet per second, according to the kind and dryness of the material being planed. The full power of the exhauster can only be felt at the planing-machine by means of large pipes and close-fitting hoods. The hoods should fit down as closely as is possible around the point where the shavings are to be made. See *Blower*, *Iron*, and *Steam-fan*.

FANTASSIN.—A foot-soldier. This term is derived from the Italian *fante*, a boy, the light troops in the fourteenth and fifteenth centuries being formed of boys who followed the armies and were formed into corps with light arms; hence the origin of the word.

FARCY.—A contagious disease among horses, depending upon the same causes as glanders, which it usually precedes and accompanies. The absorbent glands and vessels, usually of one or both hind-limbs, are inflamed, tender, swollen, hard, and knotted. The vitiated lymph thus poured out softens, and ulcers or farcy-buds appear. Unlike the ulcers of glanders they are curable, but require time and care. They must be scarified with the hot iron, which, to prevent their spreading, may also be gently run over the adjacent sound skin. Good feeding and comfortable lodgings are essential, and if they do not interfere with the appetite, give tonics, such as a dram each of sulphate of copper and iodine, repeated twice a day.

FARRIER.—A person who shoes horses and treats their diseases. The better class of Farriers often were, and indeed still are, men of great shrewdness and observation, sometimes possessing considerable experience, and with skillful, useful hands. Their management of sick horses is occasionally sensible, but generally altogether empirical. They have usually but crude ideas of the structure, functions, or diseases of animals, and pin their faith mainly on a few carefully-cherished recipes. To their calling as horse-doctors and shoeing-smiths they usually unite those of cow-leech and cutter of colts and pigs; and although still met with in many of the rural districts of England and Ireland, their practice is passing into the hands of regularly educated Veterinarians. In the United States army one Farrier is allowed to each troop of cavalry.

FARRIER-MAJOR.—A person formerly employed by the Colonel of a Dragoon Regiment to superintend the Farriers of troops. He has since been superseded by a Veterinary Surgeon. In the English army Farriers-Major and Farriers are Non-commissioned Officers in the Cavalry, Artillery, Engineers, and Military Train, whose duty it is to shoe the horses of the corps, and, generally, to assist the Veterinary Surgeon in exercising a proper care over the regimental animals. They receive the same pay as other Sergeants (with whom they rank); and, in addition, certain allowances proportionate to the number of animals in charge. The sum necessary to defray this allowance for a year is about £10,000.

FARROW COMBINATION-TENT.—This novel combination shelter, storm, and common tent, designed for active field-service, consists of a peculiarly shaped sheet of light canvas or other suitable material, having a strong cord and flaps (several inches wide) about its edges and furnished with *hooks* and *rings* or *tapes* at suitable intervals. The shape of the tent is described as follows: A B D C, in Fig. 1, is a rectangle; B F = $\frac{1}{2}$ F D; A E = $\frac{1}{2}$ E C; B F D and A E C are right angles. For *regular troops* C D = 6 feet, and for the *officer's tent* C D = 7 feet. The shape of the canvas is such as to permit its being secured about the kit so as to thoroughly protect it—the triangular end-flaps being folded over before rolling; also, when folded over from both sides along lines parallel to A C and B D, and at distances from them a little less than one fourth of C D, as in Fig. 2, to form an excellent bed-covering for a single sleeper. When spread upon the ground, the blankets are placed upon the central portion of the rectangle A B D C. In this manner a double layer of canvas covers all of the sleeper (his feet resting along the line A B) except his head, which appears at the triangular opening D H C. When used as a shelter-tent, the edges E C, C D, and D F rest upon the ground. When pitched in this manner the tent covers a maximum *available* space for a minimum canvas, with the following advantages: 1st. Quickly, easily, and securely pitched. 2d. The tent is composed of but one piece of canvas—the allowance of one man. 3d. Three of its faces are covered, two of which may be raised for the purposes of ventilation. 4th. By attaching a blanket, extra piece of canvas, or a second tent along the upper edge, the fourth face may be closed; or, by varying its inclination, more or less shade may be secured.

Two of these tents may be so combined as to form a tent having a large base and a small altitude, that will withstand a *wind storm* (a component less than one half of the force of the wind tending to overturn it). In consequence of the gradually sloping walls, there is much

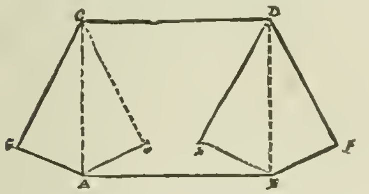


Fig. 1.—Form of Section-covering for Bed or Clothing.

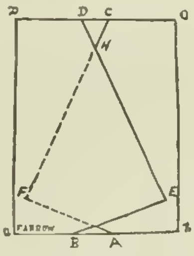

Fig. 2.—Bed-covering for Single Sleeper.

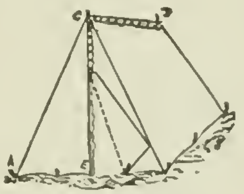

Fig. 3.—Used as a Common or "A" Tent.

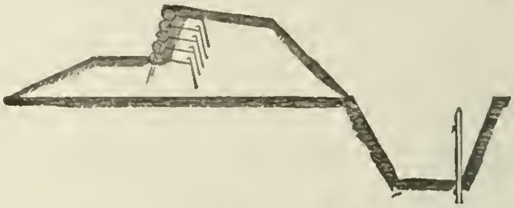
available space for the purposes of shelter and sleeping. By subjecting the canvas to a water-proofing process, it will shed the water during a *rain-storm* when pitched in this manner, and will not become heavy by wetting. If concealment be desirable, this form of tent is particularly valuable. Fig. 3 shows how two *shelters* may be combined so as to form the common or "A" tent. Here the canvas is reversed. The edge C D is at the ridge, and the edges E A, A B, and B F rest upon the ground. The poles used for the shelters are joined *two and two*, and form the long poles required for the common tent. This form of tent is particularly desirable during rain-storms, and is well suited for officers and others, living two in a tent, who are liable to become separated at any time. It moreover furnishes a covering for the kit of each, and the individual will at all times have his proper allowance of canvas with his own bedding, or in case of forced marches, etc., he may carry it on his person or behind the saddle. The poles are made of *strong and light wood*, with plain ferrule-joints and projecting screws, which serve to strengthen the joints and hold the corners of the canvas in place, being run through a worked hole or ring arranged for the purpose. The shelter-tent may be neatly pitched, without poles, whenever it is possible to suspend the ridge-rope (formed by uniting the guy-ropes) between trees or their branches, piles of stores, saddles, aparejos, rocks, etc.; or it may be pitched against a fence, fallen tree, etc. When without poles or any facilities on the open prairie, either the carbine or ramrod will make a good substitute.

The following extract from the proceedings of a Board of Officers convened at West Point, N. Y., to examine and report upon the merits of this tent will serve to point out its capabilities:—Dimensions of Officer's Tent pitched: First, as a shelter-tent. Base 7 feet square, 3½ feet high. Second, as a storm-tent, combining two shelter-tents, omitting the poles of one. Base 7 feet by 14 feet; 3½ feet high. Third, as a common or "A" tent. Base 7 feet square; 7 feet 2 inches high. Weight, including poles, 3 pounds 2 ounces. The following are some of the advantages of the tent: 1. Capable of subdivision. 2. Maximum *available* space for minimum canvas. 3. Same poles for each form of tent. 4. The tent is expeditiously pitched. 5. As a shelter-tent it is far more secure and roomy than the one now used. 6. Three faces of the tent are covered, and the fourth may be covered by a blanket or odd piece of canvas. 7. No ridge-pole is required. 8. The only ropes required may be used to tie up the bundle. 9. It is a superior wrapper for the bundle. 10. When not pitched it serves, on account of its peculiar form, as an excellent bed-covering. 11. It is the only practicable storm-tent, and to this point the Board particularly invite attention. 12. It forms a roomy and convenient "A" or common tent, and as it can be opened at both ends, it can be rendered more comfortable in warm weather than the old tent. 13. Thirty-four tents (officers') or forty tents (men's), with poles in suitably-constructed bags, form a handy pack for a mule. The common tent is here referred to. 14. If transportation is abandoned, the tent is readily borne on the person. 15. It is readily adapted to the wind- or rain-storm. 16. The shelter-tents are easily put together to form a *secure* storm or common tent. In conclusion, the Board is of the opinion that if "Farrow's Portable Combination Shelter, Storm, and Common Tent" is adopted, it will prove a valuable addition to the camp-equipage now issued. See *Tent*.

FARROW KNIFE-TROWEL AND TENT-PEG.—An invention designed to combine the intrenching-tool and a great many other necessary articles for field-equipment. The scabbard (one edge sharp) is of the same shape and size as the blade of the trowel-bayonet. A knife (rasp, saw, or any other article required by the particular man who uses it) enters the scabbard and is retained in position by means of a small but strong spring. The back edge of the scabbard is prepared so as to form a convenient wrench, screw-driver, shell-extractor, etc.; while to the upper and outer edge is attached a small neck and ring, so as to convert it into a suitable tent-peg or picket-pin when driven into the ground. While on the march the scabbard, with knife encased, is hooked to the belt and worn at the side. For intrenching and chopping purposes the whole is unhooked and used. To use the knife it is simply drawn from the scabbard; and after arrival into camp, the scabbard (with or without the knife) is driven into the ground wherever needed, as a picket-pin or tent-peg. Each soldier might be provided with a *knife-trowel*, to be worn on the body; and each cavalryman, packer, etc., might have attached to his saddle an additional trowel, containing a rasp, saw, etc.

FASCES.—Bundles of rods usually made of birch, but sometimes of elm, with an axe projecting from the middle of them, which were carried before the Chief Magistrates of ancient Rome, as symbols of their power over life and limb. They were borne by the Lictors, at first before the Kings; in the time of the Republic, before Consuls and Prætors; and afterwards before the Emperors. Their number varied, a Consul having twelve, and a Prætor six; but within the city only two. Valerius Publicola introduced a law that within the city the axe was withdrawn, except in the case of a Dictator, who was preceded by 24 Lictors, bearing as many fasces. Publicola also made the fasces be lowered at the assemblies of the people, as an acknowledgment of their supreme power.

FASCINE REVETMENT.—To form a fascine revetment, the first row of fascines is imbedded about half its thickness below the tread of the banquette, and is secured by means of the anchoring-stakes, and also by several stakes driven through the fascine itself about 12 inches into the earth. The knots of the ties are laid inside, and the earth of the parapet is well

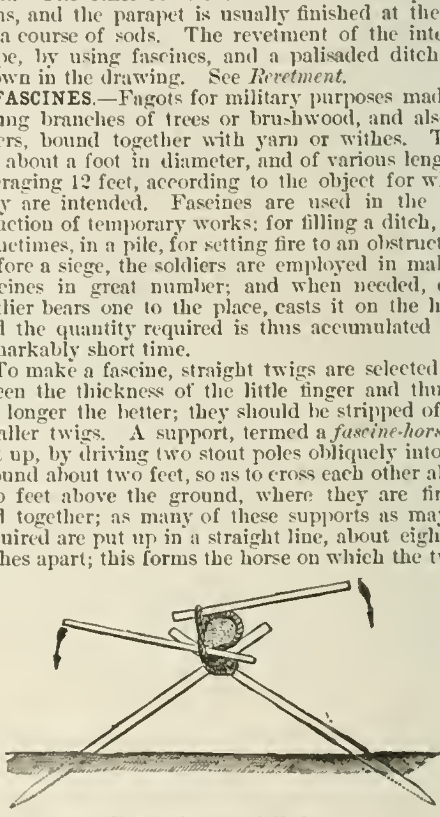


Fascine Revetment and Palisaded Ditch.

packed behind the fascine. A second row is laid on the first, so as to give the requisite interior slope; it should break joints with the first row, and be connected with it by several stakes driven through them both. The other rows are laid with similar precautions, and the parapet is usually finished at the top by a course of sods. The revetment of the interior slope, by using fascines, and a palisaded ditch are shown in the drawing. See *Revetment*.

FASCINES.—Fagots for military purposes made of young branches of trees or brushwood, and also of osiers, bound together with yarn or withes. They are about a foot in diameter, and of various lengths, averaging 12 feet, according to the object for which they are intended. Fascines are used in the construction of temporary works: for filling a ditch, and sometimes, in a pile, for setting fire to an obstruction. Before a siege, the soldiers are employed in making fascines in great number; and when needed, each soldier bears one to the place, casts it on the heap, and the quantity required is thus accumulated in a remarkably short time.

To make a fascine, straight twigs are selected, between the thickness of the little finger and thumb, the longer the better; they should be stripped of the smaller twigs. A support, termed a *fascine-horse*, is put up, by driving two stout poles obliquely into the ground about two feet, so as to cross each other about two feet above the ground, where they are firmly tied together; as many of these supports as may be required are put up in a straight line, about eighteen inches apart; this forms the horse on which the twigs



Fascine-horse and Choker.

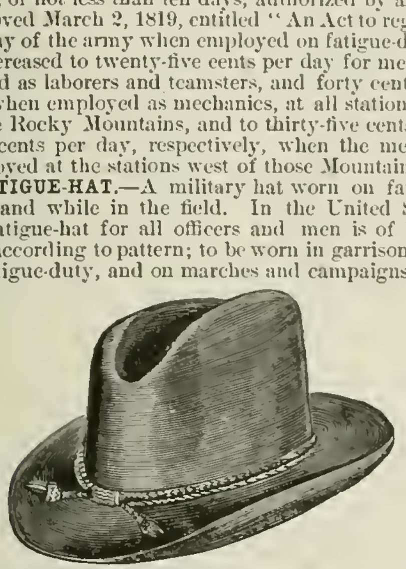
are laid to be bound together. A machine, termed a *fascine-choker*, is formed of two stout levers about five feet long, connected near their extremities by a chain or strong cord, which should be long enough to pass once round the fascine, and be drawn tight by means of the levers. The twigs are laid on the horse with their large and small ends alternating; the choker is applied to bring them together, and they are bound by wire, or by withes made of tough twigs, properly prepared by twisting over a blaze, so as to render them pliable. The ties are placed 12 inches apart, and every third or fourth one should be made with an end about three or four feet long, having a loop at the extremity to receive a stake through it. This stake is termed an *anchoring-stake*, its object being to secure the fascine very firmly to the parapet. See *Fascine Revetment*.

FASTNESS.—A well fortified place; a stronghold; a fortress or fort; a castle, etc.

FATIGUE-CALL.—A particular military call, sounded on the bugle or drum, by which soldiers are called upon or assembled to perform fatigue-duties.

FATIGUE-DUTY.—The term *fatigue* is applied to the labors of military men distinct from the use of arms. Extra pay is provided for all soldiers performing the authorized fatigue-duties. The following law was enacted as early as 1854: That the allowance of soldiers employed at work on fortifications, in surveys, in cutting roads, and other constant labor, of not less than ten days, authorized by an Act approved March 2, 1819, entitled "An Act to regulate the pay of the army when employed on fatigue-duty," be increased to twenty-five cents per day for men employed as laborers and teamsters, and forty cents per day when employed as mechanics, at all stations east of the Rocky Mountains, and to thirty-five cents and fifty cents per day, respectively, when the men are employed at the stations west of those Mountains.

FATIGUE-HAT.—A military hat worn on fatigue-duty and while in the field. In the United States the fatigue-hat for all officers and men is of black felt, according to pattern; to be worn in garrison only on fatigue-duty, and on marches and campaigns. In



United States Regulation Fatigue-hat.

extreme southern latitudes, in summer, Commanding Officers are authorized to sanction, on duty, the straw hat, to be bought, out of the pay of the soldier, of the local merchant or trader. Whenever straw hats are worn by enlisted men, the officers must in like manner wear them. The wearing of the fatigue-hat is generally optional. The forage-cap may replace it.

FAUCHARD.—A formidable weapon of the sixteenth century. It resembled a very large razor-blade fixed to the end of a staff.

FAUCRE.—A kind of hook which served to fix the heavy lance to the cuirass. It was used in the twelfth century, when tournaments became a regular practice and when very heavy lances were employed.

FAUDES.—A species of kilt of armor, or iron petticoat. It is known as *taces* in England.

FAULCON.—A very small cannon employed by the ancients. See *Falconet.*

FAULX.—An instrument very much resembling a scythe. It was often used to defend a breach, or to prevent an enemy from scaling the walls of a fortified place. This weapon was first resorted to with some success when Louis XIV. besieged Mons. On the surrender of that town, large quantities of faulx, or scythes, were found in the garrison.

FAUSSE-BRAIE—FAUSSE-BRAYE.—A low rampart encircling the body of a place, and raised about three feet above the level ground. This work has been mostly discarded by modern engineers, except when used in front of curtains, under the name of *tenailles.* The French engineers gave this title to the work, as an adaptation from the Italian term *fossa brea*, which had its origin from the fausse-braie being commonly in the ditch, in front of the main wall. The fausse-braie had the advantage of giving an additional tier of guns for defensive purposes, but the still greater disadvantage of affording facilities for the scaling of the parapet. In many of the places constructed before Vauban's time there was a fausse-braie, enveloping the enceinte and connected with it. This work was suppressed by Vauban, who was the first to use the tenaille in its place.

FAUSSTOURNIER.—A description of tournament practiced at the close of the twelfth century.

FECIAL.—Pertaining to heralds, and the denunciation of war to an enemy; as, fecial war.

FEDERAL GOVERNMENT.—A body-politic composed of the people of several different and in some respects independent States, over which, in its own prescribed sphere, it exerts a supreme authority; while outside of that sphere the States and the people thereof are sovereign within their respective jurisdictions. The character of a Federal Government varies with the extent of its powers. The first form of Federal Government established in this country was that of the "Articles of Confederation," adopted during the War of the Revolution, July 9, 1778. The separate Colonies, finding some form of Central Government indispensable to the efficient prosecution of the War of Independence, gave a reluctant consent to those Articles, which, while the war lasted and all felt the presence of a common danger, worked tolerably, though not without some embarrassing friction arising from notions of Colonial or State Sovereignty. But after the Independence of the country was established, and the pressure of a common danger no longer existed, there was a disposition to exalt the State, and to depreciate the National Authority, which to some extent was regarded as a burden. The National Government had no judicial tribunal to make an authoritative exposition of its powers, and no executive officers to enforce its decrees; it was entirely dependent upon the voluntary action of the States for means to carry on its operations; so that, in the language of Washington, it was "little more than a shadow without the substance," and "Congress a nugatory body, their ordinances being little attended to." There was, in short, an utter want of all coercive authority on the part of the Government to carry into effect its own constitutional measures. The embarrassments growing out of this state of things were endured till 1787, when a Convention of Delegates from the several States was held in Philadelphia "for the purpose of revising the Articles of Confederation and reporting to Congress and the several Legislatures such alterations and provisions therein as shall, when agreed to in Congress and confirmed by the States, render the Federal Constitution adequate to the exigencies of the Government and the preservation of the Union." The Convention encountered many difficulties arising from diversities of opinion among its members, and from conflicting local interests, but finally succeeded in framing a Constitution which the people of the several States finally ratified, and which, with various Amendments, has continued to this day. From the time of its adoption different theories of interpretation have prevailed, and these conflicting theories, to a greater or less extent, have determined the character and aims of political parties. It has been contended on the one side that the Union was merely a league between the several States in their organized capacity, and that each State had the right, at its pleasure, of withdrawing therefrom. On the other side it has been held that the Union, instead of being the creation of the States, as such, was formed by "the people of the United States," acting indeed through their respective State Organizations, but still as citizens of a common nationality. According to this theory no right of secession on the part of a State has any existence, but it is the right and the duty of the National Government to maintain the Union by force. This question was brought to an issue in the late Rebellion, the slaveholding States seeking to exercise the assumed right of secession for the protection of slavery, and the non-slaveholding States taking up arms for the defense of the Union. The results of the war are generally regarded as a vindication of the anti-secession theory, though there are still some disputed questions concerning the relative powers of the National and State Governments. See *Constitution.*

FEED-DRUM.—The contrivance by which the supply of cartridges to certain machine-guns is made. In the Gatling gun it consists of a metal framing of cylindrical shape, having twenty divisions or slots around its circumference, radiating from the center. Each division contains twenty cartridges, placed one above the other in a horizontal position. A hole in the center of the drum fits over a pin on the hopper-plate. The cartridges are fed to the carrier below, and thence to the barrels. The cartridges pass to the hopper through an aperture at the bottom of each division of the drum. On the bottom face of the drum is a projecting rib, which fits into a slot on the hopper-plate, to steady the drum when firing. On its lower periphery the drum has a series of thumb-lugs by which it is revolved. A small brass weight in each division is caused to bear upon and slide down a groove provided for it, so that it follows the cartridges as they descend, and prevents their becoming choked in the divisions.

To fill the feed-drum, invert it and unlock it, turn the bottom plate until the hole in the plate comes directly over a division of the drum, then raise the brass weight and fill in the cartridges regularly, the bullets being placed toward the center of the drum, letting the weight descend slowly until the division is full. Proceed in like manner with the remaining divisions; then lock the plate and place the drum upright. The improved feed lately devised has not only greatly increased the direct fire, but is of inestimable value in enabling the gun to deliver high angle or mortar fire so as to drop the balls on men behind intrenched positions at all distances from 200 to 3500 yards with deadly effect. Tables of distances and elevations have been established to obtain with certainty the above result. Experiments with the gun have proved that bullets so discharged come down nearly perpendicularly, and with force sufficient to penetrate from 2 to 5 inches of timber. With this new feed there is no possible chance of the cartridge jamming, even when the gun is used by inexperienced men. It is beyond doubt the most valuable improvement at any time made in machine-guns. See *Gatling Gun.*

FEIGNING DISEASE.—A ruse much practiced in the Army and Navy, and also by convicts and others anxious to escape from discipline or procure a discharge from compulsory service. In the Army it is technically called *malingering.* The detection of feigned disease, of course, necessarily belongs to the highly educated Physician, and is impossible without a thorough knowledge of the reality, unless, indeed, the imitation be very coarse and badly studied. The diseases most commonly simulated are epilepsy, catalepsy, convulsions, blindness, deafness, palsy, insanity, indigestion, neuralgia, rheumatism, palpitation of the heart, and generally all disorders which may exist without leading to any distinct external appearances. Ulcers of the legs, however, have often been made, and kept open artificially through the application of irritant substances; and vomiting or coughing up of blood is very easily simulated, if the supposed patient can get access to the necessary materials in the slaughter-house or elsewhere. The detection of such impostures is easy or not according to the opportunities and knowledge and skill of the deceiver, as compared with those brought to bear on the discovery of the fraud. Many men in the public services, and women affected with hysteria, have become so expert as to deceive even men of high character and skill. There is one instance on record in which a man submitted to successive amputations of the arm upwards nearly to the shoulder, for an ulcer produced and kept open at will by local applications; and a case was some time ago recorded by Dr. Murchison in the *Medico-chirurgical Transactions*, in which there is no reasonable doubt that a large opening into the stomach was the result of caustic substances deliberately applied to the abdomen, with the view of exciting sympathy.

FEINT.—1. In military or naval matters, a mock attack or assault, usually made to throw an enemy off his guard against some real design upon his position. 2. In fencing, a seeming aim at one part when another is intended to be struck. See *Fencing.*

FELLOES.—The parts of a wheel which form its circumference. The felloes fulfill the following offices: 1. They furnish a secure seating for the head of the spoke. 2. They connect spokes and tire rigidly together. 3. They support and stiffen the tire, acting as a beam between each pair of contiguous spokes. The felloes are made of timber having a long straight grain or fiber. Each felloe should be so restricted as to its length compared with its depth, that the tangent to the inner arc, or *bosom,* at its central point shall not intersect the outer arc, or *sole.* By this provision the interior fiber at the center of the felloe spans its entire length, contributing its support to the weakest parts, which are at the extremities. The tongue-holes for the spokes must be separated far enough from each other and from the ends of the felloe to allow of a sufficiency of intervening material to withstand all pressures and wrenches from the tongues and adjoining felloes without splitting. Experience has proved that the number of felloes in a five-foot wheel can safely be limited to *six*, each of which is enabled to receive two spokes without endangering its strength. One bolt passing through each felloe and the tire is sufficient to prevent side-shifting. See *Wheel.*

FELL RAILWAY.—The railway under this name was well known to travelers proceeding to or returning from India, as it was the only means of going over Mont Cenis, in Italy, before the tunnel was bored through the mountain. This nature of rail has been found useful during war-time, and did good siege-service during the Franco-German War. The gauge is 18 inches. Each truck carries three tons. Five hundred unskilled workmen can lay a mile in a day.

FELTRE.—A cuirass made of strong woolen cloth, much worn in early times by the Romans and others.

FENCE.—Self-defense by the use of the sword; the art and practice of fencing or sword-play.

FENCIBLE.—1. A soldier enlisted for the defense of the country, and not liable to be sent abroad. 2. Capable of being defended, or of making or affording defense. See *Fencibles.*

FENCIBLE LIGHT DRAGOONS.—A body of cavalry raised voluntarily in various Counties of England and Scotland in 1794 to serve during the war in any part of Great Britain. This force was disbanded in 1800.

FENCIBLES.—Regiments formerly raised for local defense, or at a special crisis and for a limited time. The officers had the same rank as officers of militia, according to the dates of their respective commissions. The only English regiment now bearing this title is the Royal Malta Fencible Artillery.

FENCING.—The art of defending one's own body or assailing another person's in fair fight by the aid of a side-weapon—i.e., by a sword, rapier, or bayonet. Technically, fencing is usually limited to the second of these; and works on the art touch only on attack and defense with the foil in pastime, and the rapier in actual personal combat. The objection formerly existed that instruction in fencing encouraged a propensity to dueling; but as that absurdest of absurd customs has entirely ceased to demand its annual victims, no such objection now holds. Fencing may therefore be safely learned and taught as an elegant and manly accomplishment, developing gracefulness and activity, while it imparts suppleness to the limbs, strength to the muscles, and quickness to the eye. This regards fencing with the foils (the rapier has disappeared with the duels which employed it); but instruction in fencing with the sword and bayonet, while conferring the same advantages, has in addition the recommendation of helping to fit the student for taking an active part in any general national defense that political circumstances might render necessary. The foil is a circular or polygonal bar of pliable and very highly tempered steel, mounted as any other sword, and blunted at the point by a "button," to prevent danger in its use. From its nature, the foil can only be employed in thrusting, and, being edgeless, it can be handled without liability to cutting wounds. The length of the blade should be proportioned to the height of the person using it—31 inches being the medium length for men, and 38

FIG. 1.

FIG. 2.

FIG. 3.

inches from the hilt to point the maximum allowable. As a protection against accidental thrusts, the face is generally guarded by a wire-mask. The two portions of the blade are known as the "forte" and the "foible;" the first extending from the hilt to the center, and the other from the center to the point. In fencing there are three *openings* or entrances—the *inside*, comprising the whole breast from shoulder to shoulder; *outside*, attackable by all the thrusts made above the wrist on the outside of the sword; and the *low parts*, embracing from the armpits to the hips. For reaching and guarding these entrances there are five positions of the wrist—prime, seconde, tierce, carte (quarte), and quinte. The most important, and those to commence with, are carte and tierce, from which are derived the subordinate positions of carte over the arm, low carte, and flanconnade or octave. To *engage* is to cross swords with your adversary, pressing against his with sufficient force to prevent any maneuver taking you unawares. To *disengage* is to slip the point of your sword briskly under

FIG. 4.

his blade, and to elevate it again on the other side, pressing in a direction opposite to that of the previous case. The *guard* in each position is a passive obstruction to the opposing *thrust;* the *parade* is an active obstruction in which the guard is first assumed, and the blade then pressed outward or inward by a turn of the wrist against the adversary's sword, so that when thrust at your body it shall be diverted from its aim and held off. The parade may therefore be regarded as a mere extension of the guard. If the parade were called the "parry," it would convey its meaning more readily to English ears. Another and perhaps more appropriate name for thrust is the "lunge" or "longe," as the thrust is almost always accompanied by a lunge forward of the right foot, to give at once greater force and longer command to the blow.

The fundamental principle of fencing consists in the execution of the right arm, the longe, the recovery; advancing and retreating quickly; and lastly, not least, a good opposition, which is one of the most essential things, as you are guarded at least on one

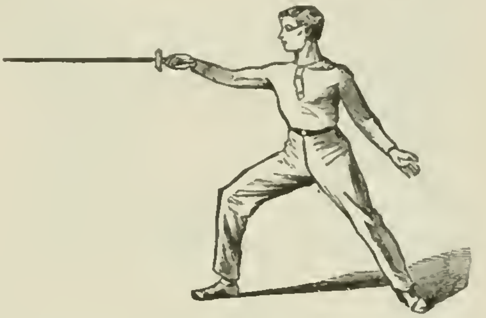


FIG. 5.

side. This will also give the advantage of knowing what your adversary intends doing, which you must endeavor to discover by the feel of his foil.

First Position of the Body.—Place the right heel against the left ankle, so as to form a right angle with both heels, the foil to be held in the left hand under the hilt with the thumb and fingers, the right hand straight on the outside of the right thigh, shoulders square and pressed rather backward, eyes turned toward the adversary, showing the right breast to the front, without constraint. (Fig. 1.)

Second Position.—Bend the right arm as high as the elbow, and at the same time bring it across the body; take hold of the foil, thumb stretched along the convex. In this movement the body must be kept quite steady, shoulders square, eyes front, head up without appearing stiff, knees perfectly straight, waist in. (Fig. 2.)

Third Position.—Raise both hands above the head, holding the button of the foil with the thumb and first finger of the left hand, turn your eyes to the right, so as to see your opponent full in the face. (Fig. 3.)

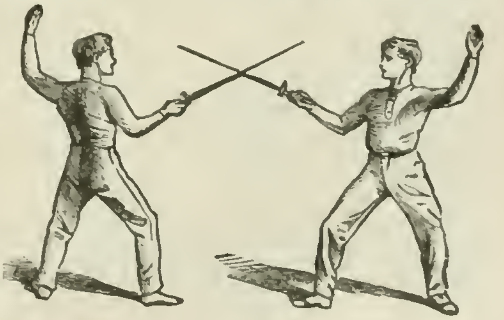

FIG. 6.

Manner of Holding the Foil in Hand.—Let the concave of the handle rest in the palm of the hand, the thumb stretched along the convex, the first finger about half an inch in advance of the thumb; the foil should only be held firm in the hand when parrying or thrusting, otherwise the fingers and thumb will get stiff from grasping it too long.

On Guard in Carte.—Bend both knees together until they are in a perpendicular line with the toes; step out with right foot in a direct line from the left ankle, about twenty-two inches or more, according to the length of the legs; keep the left arm up and bent, so as to form a half-circle as high as the head, palm of the hand turned toward the left face; keep the body upright, the weight to be kept equally on both legs; bring the point of the foil down to the height of your adversary's left eye. This is the engage of carte; arm bent and the elbow drawn inward, the hand as high as the center of the chest. (Fig. 4.)

The Half-longe.—1. Straighten the right arm with-

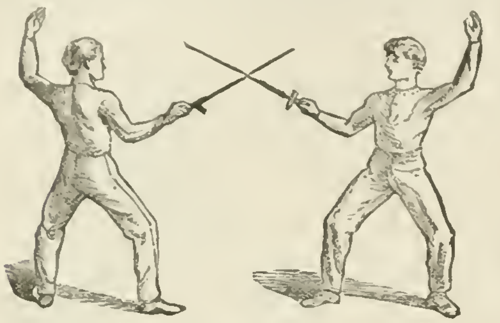

Fig. 7.

out moving the body, point of the foil as high as the chest of the opponent, hand as high as your face. 2. Throw the left hand backward, at the same time press the shoulder well back, palm of left hand to the front, about four inches from the thigh. 3. Straighten the left knee and incline the weight of the body forward on the right, without moving the foot from the ground. *To Recover.*—1. Bend the left knee. 2. Throw the left arm upward to the position of the guard, bear the weight of the body again equally on both knees, right arm bent, elbow turned inward; stand firm on guard without appearing stiff; head held easy and upright.

The Longe.—1. Extend the right arm, direct the point of your foil to the height of your chest, longe in carte, looking over the right arm, the hand as high as your face. 2. Throw the left hand backward to within four inches of the left thigh, palm of the hand to the front; press the shoulders well back. 3. Straighten the left knee and keep the foot flat on the ground. 4. Longe forward in a direct line from the left ankle about forty inches or more, according to the length of the limbs, until the right

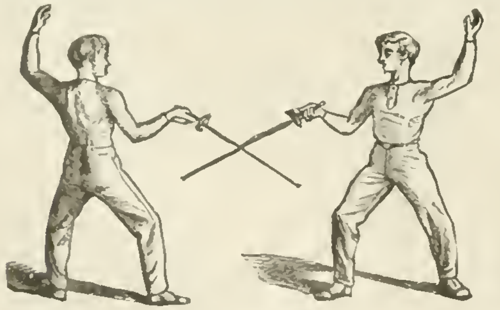

Fig. 8.

knee is in a vertical line with the instep, toes turned out. (Fig. 5.) These four motions should be repeated often, so as to give freedom of action to all the joints. *To Recover.*—1. Bend the left knee back. 2. Throw the left hand upward to the position of the guard, palm of the hand turned inward toward the left face, arm bent. 3. Bring the right foot up to the guard, supporting the weight of the body equally on both knees. 4. Bend the right arm, nails upward, point opposite the face, hand as high as the chest, elbow rather inward, head kept up.

To Advance and Retire.—Being on the guard, to *advance*, take one step forward with the right foot, about twelve inches, bring up the left foot directly, keeping the same distance between both feet, as if making one movement with both; the knees equally bent, the body held upright, eyes fixed on the opponent or object in front. To *retire*, take one pace back with the left foot, bringing the right foot up immediately, at the same time beat once with the flat of the right foot firmly on the ground. The distance

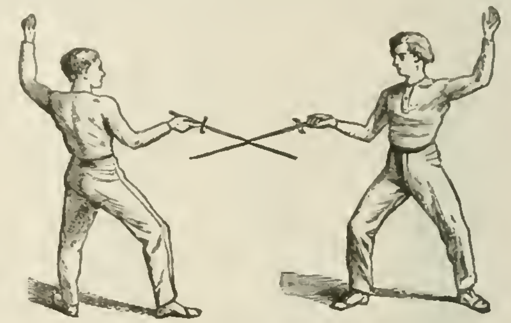

Fig. 9.

in walking backward should be longer than the advancing by two or three inches, taking care that the weight of the body is kept equally on both feet; the left breast should be turned slightly toward the adversary. Having practiced these movements frequently, finish by beating twice with the right foot, bringing up the left foot, and right hand under the chin, lastly straightening the right arm on the right side.

The Engage of Carte—Inside Guard High.—Being engaged in carte with an adversary, turn the nails upward, cross foils about nine inches from the button: this half of the foil is called the *foible*, from being the next part to the end; the other half is termed the *forte*, or part next the hilt. Oppose the opponent's foil sufficiently to prevent him from touching you in the engage, keep the right arm bent inward, point of your foil opposite your adversary's face, right arm as high as your chest. (Fig. 6.) If your opponent does not cover himself in the engage, straighten your arm, lower the point to his chest, longe in carte, looking over the right arm, hand as high as the face, recover and engage in carte, crossing foils as before.

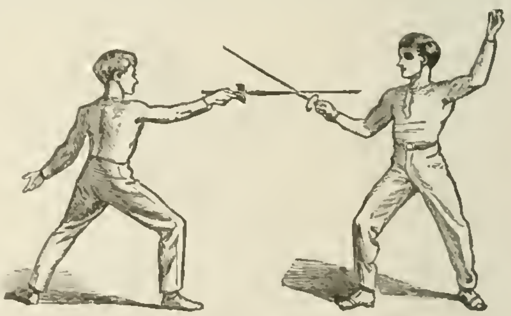

Fig. 10.

The Engage of Tierce—Outside Guard High.—This being the opposite guard to carte, it only differs from it in the position of the hand, nails of which are turned downward. Engaged in tierce, join foils as in carte; if your adversary is not well covered in the engage, straighten your right arm by lowering the point to his chest, longe in tierce, looking inside the arm, shoulders pressed well back, left foot firm on the ground, left knee straight, the body not thrown forward but rather upright; recover in tierce. (Fig. 7.)

The Guard of Half-circle—Inside Guard Low.—The half-circle guard is generally used against the thrust of seconde and low carte. The guard is generally taken in the following manner: Raise the hand as high as the left shoulder, nails upward, the elbow turned well in toward the body, the foil to be held firm in hand and opposed to your adversary, the point as low as your opponent's waist. If an opening should occur, raise the point and return carte. (Fig. 8.) The guard of octave is the opposite guard to the half-circle, and is used against the thrust of octave; it also prevents the adversary from counter-disengaging.

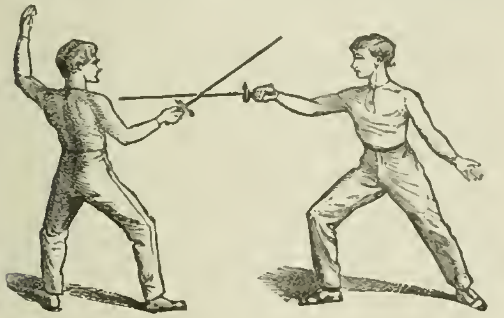

FIG. 11.

Raise the hand as high as the chest, keeping the point as high as the lower part of your opponent's chest. This is a very useful parry in returning the thrust of low carte.

The Disengage from Carte. — If your adversary presses your foil, lower your point to within about two or three inches of his hilt, at the same time passing it to tierce, straighten the right arm, and longe; recover in carte. (Fig. 9.)

The Feint of One, Two.—Being engaged in carte, if your opponent takes the guard of tierce when you disengage on him, return back to carte and longe, making the movement quickly from the fingers, not from the shoulder; right arm quite straight, nails upward, look over the right arm; recover in carte. (Fig. 10.) *The Feint of One, Two, Three.*—Engage in carte as before, disengage to tierce, again in carte. In both cases raise the point of your foil as high as your opponent's face, arm kept straight, return again to tierce, point to the chest of your adversary, and longe in tierce, looking inside your arm, shoulders pressed well back, body upright; recover in carte. (Fig. 11.)

The Disengage from Tierce.—Engage in tierce. As

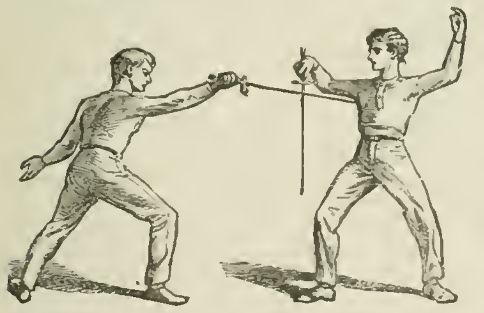

FIG. 12.

soon as your opponent presses your foil, lower your point, straightening the arm, at the same time pass your foil to carte, longe with the knuckles turned upward, taking care that the left foot does not quit the ground; recover in tierce. *The Feint of One, Two.*—Engage in tierce. Disengage to carte, pointing to the face of your adversary, arm straight, the body kept steady; the moment your opponent takes the simple guard of carte, return to tierce, longe, looking inside the right arm; recover in tierce. *The Feint of One, Two, Three.*—Being engaged in tierce, disengage to carte, again to tierce, extending the arm in the first disengage; finding that he takes the simple guards each time, return to the carte, longe, looking over the arm, left knee always being kept straight in the longe; recover in carte.

Wrist Practice.—An excellent practice for the wrist is for two persons to practice the counters of carte and tierce. This is done in the following manner: Being engaged in carte, your adversary disengages on you, take the counter of carte, and disengage on him without touching, unless, by mutual agreement, he

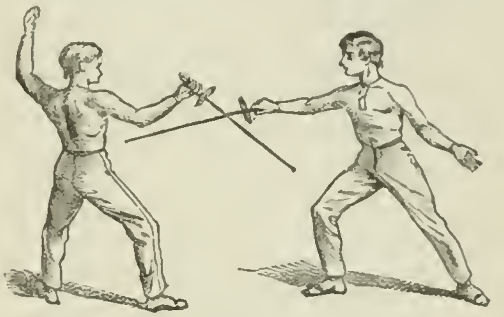

FIG. 13.

takes the counter of your disengage; keep repeating this for some time; then engage in tierce, the opponent disengages, take the counter of tierce, disengage on him; continue this also for some time, and change again to counter-carte. These practices will soon make the wrist supple and strong—the two essential things for fencing.

The Parade of Prime.—Being engaged in tierce, your adversary tries to get in by main force; bend your arm and wrist, turning the nails downward at the same time, raise the hand as high as your chin, drawing the arm inward as you raise the hand, the point of your foil directed toward the lower part of the chest of your adversary; parry and longe in seconde, recover quickly in tierce. (Fig. 12.)

Thrust of Sixte. — After having parried prime, should your opponent keep his hand low in trying to get in by force in tierce, turn the knuckles upward quickly, bring the point over his arm, thrust sixte over the arm by binding his foible with your forte: this must be done by a quick turn of the wrist.

The Parade of Seconde.—Engaged in tierce, if your adversary should drop his point, parry the seconde by

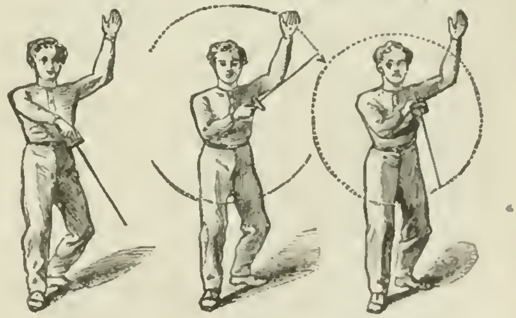

FIG. 14.

giving a dry beat on the foible of his foil with the forte of yours, nails downward, hand opposed, so as to prevent him touching you in the longe, point to the lower part of his waist, holding the head well up, the body not to be thrown too much forward, otherwise you cannot recover quickly; recover in sixte. (Fig. 13.)

The Feint of Seconde.—Being engaged in tierce, drop your point under the hilt of your opponent, principally with the fingers, nails downward, but without lowering the hand, return directly back again, longe by turning the nails upward in sixte, over the arm, or return back to seconde again, longe and recover in tierce. This is called the feint of seconde and tierce.

The Parade of Quinte.—This parade is used in the same side as carte inside guard, and taken in the following manner: The hand as high as the breast, nails turned downward, parry and longe in seconde or carte over the arm. The parry is mostly taken when the adversary thrusts low. It is also a very quick return thrust when your adversary keeps his hand too low, or drops the point to feint for the lower part of your body.

The Parade of Sixte.—This parade only differs from tierce in the nails being turned upward instead of downward. The hand must be kept as high as the shoulder; point as high as your adversary's face if your opponent is not well covered, straighten the arm, longe with the nails upward, recover; if he presses, disengage in carte. The feint of one, two, and one, two, three, is generally made from this position.

The Parade of Counter-carte.—Having joined foils in carte, nails upward, as soon as your adversary disengages, follow his foil by making a small circle until you meet it again in carte; if he disengages a second time, take the simple guard of tierce. This is one of the best and safest parries in fencing, as it stops most of the feints. Being engaged in tierce, if the opponent feints one, two, take the counter of carte in the same manner as before; should he disengage a third time, take the guard of tierce; if he low-

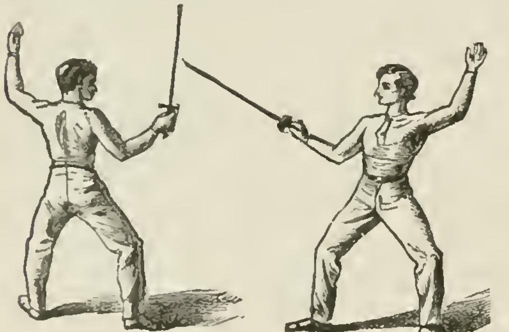

Fig. 15.

ers the point, take the half-circle, returning again to carte. (Fig. 14.) When your adversary stretches his arm to thrust, give a beat on the foible of his foil with the forte of yours, so as to make an opening for your thrust. This may also be done in the counter of carte, when your opponent is not too close.

The Parade of Counter-tierce.—This parade is performed similarly to the counter of carte, but the nails must be downward. Being engaged in tierce, if your adversary disengages, follow his foil in a circular manner until you meet it again in tierce; if he disengages a second time, take the simple guard of carte. Should he make the feint of one, two, without stopping, take the counter of tierce, as before, but be careful not to be too near, as the guard is only safely taken when out of distance: If he disengages after having feinted one, two, take the simple guard of carte. To parry tierce, turn the nails downward, keeping the foil firm in hand, to prevent being disarmed. When your opponent stretches his arm to thrust, give a dry beat on the foible of his foil with your forte, so as to throw it out of the line. Direct your point to his chest, longe either in tierce or in seconde.

Half-circle Parade.—The half-circle is generally used after having parried tierce against the thrust of seconde or low carte. For this purpose raise the hand as high as the shoulder, bend the arm, nails turned well upward, elbow drawn inward, parry and point rather low, longe in carte. To perform the counter of half-circle;—having crossed foils in half-circle, which is only done in making an assault, your opponent passes his foil over yours; follow by making a circle till you meet him again in half-circle; if he disengages again, take the guard of octave or seconde, longe and recover in tierce. Sometimes the circle may be made twice with success by keeping the hand well up, holding the foil firmly. (Fig. 14.)

The Parade of Octave.—The octave parade is the opposite guard to half-circle, and is taken to prevent the opponent from getting in by force in the lower part of the body in octave or seconde. Keep the hand as high as the center of your body, straighten the arm slightly so as to oppose your adversary, point of the foil rather low, parry and longe in tierce or octave. To perform the counter of octave, having opposed your adversary in octave, he may disengage over your foil; therefore follow his foil, immediately describing a circle until you meet his foil again in octave, taking care to keep the hand well up. If he passes over a second time, take the guard of half-circle or quinte, longe in low carte, keeping the head up.

The Cut over the Point from Carte to Tierce.—Engage in carte. If the opponent holds his hand low with the point high, raise your wrist sufficiently to clear the foil of your adversary without exposing your body. Cut with the foil over his point until it hits the center of his chest. If your adversary parries tierce, as soon as you see him take the guard, disengage under his arm by passing your point under the wrist. Longe in carte. The cut and longe should be made simultaneously. (Fig. 15.) The cut from

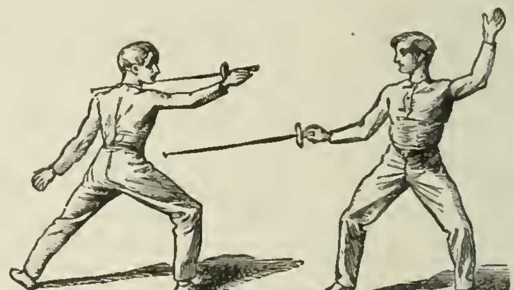

Fig. 16.

tierce to carte is made in the same manner as carte, but the longe must be in carte inside the arm; be careful that the body is well covered, and not run the risk of being hit at the same time; keep the body a little backward. If the adversary takes the guard of carte when you cut, disengage to tierce by passing your foil quickly over his wrist, arm quite straight, longe in tierce.

The Disengages.—The disengages are made when an adversary takes the simple guards, or leaves himself uncovered on either side; however, care must be taken that he does not thrust at the same time as you disengage, thereby both hitting at the same time. This can be avoided by keeping the hand opposed to the adversary either in carte or tierce, whichever you may be engaged in at the time of making the disengage, the one, two, or one, two, three. The disengage is also advantageously taken when the adversary advances or retreats. Allow him to take one pace backward, opposing his foil on either side; lower the point of your foil; longe, covering your body in carte or tierce, whichever you may be engaged in at the time. Should your opponent advance, retreat one pace, keeping a good opposition; disengage as before, longe and recover quickly on guard. The feint of one, two, and one, two, three, can be made in the same manner.

The Salute.—The salute, previous to making an assault or loose play, as it is termed, is an established form of politeness before fencing for hits; it is also an excellent practice, as it prepares the body to undergo the more energetic movements in the assault. Begin in this manner: 1. Stand, as in Fig. 1, with the foil in the left hand. Salute by presenting the right hand to your adversary as high as the chin, palm of the hand upward. 2. Bring the hand across the body, as in Fig. 2. 3. Raise both hands above the head, as in Fig. 3. 4. Step out on guard, in tierce, with your foil out of the line of your adversary's body, your opponent doing the same; now both beat twice with the right foot, leaving the body exposed; ask the adversary to thrust first, upon which he brings his point in front of your body, and longes in carte, but without touching your body. The distance of his point should be at least one inch from your breast. This is called measuring distance. Your adversary having recovered, do the same by bringing the right foot up to the left ankle, dropping the left hand, the right hand brought under the chin. From this position salute, first in carte, by turning the eyes to the left simultaneously with the foil; bring the foil under the chin again; salute in tierce, bringing the foil back once more; salute your opponent by presenting your point in front of his face; then by a circular movement made inward with both hands get on guard in carte.

Thrusting Carte and Tierce.—Engaged in carte, it being the adversary's turn to thrust first, he disengages in tierce, you parry tierce, and turn the hand to seconde, nails down, by dropping the point; your opponent's foil is now over the left shoulder, holding with the fingers and thumb very slightly. (Fig. 16.) Six disengages are to be made, that is to say, three on each side, finishing in carte. When your adversary gets on guard in tierce, engage with the foil, at the same time beating once with the right foot; now he disengages to carte, parry carte, and turn your foil in half-circle, nails up; his foil is now over the right shoulder. When he gets on guard, engage again in carte, beating once with the right foot. When he has completed the six disengages, he finishes by feinting one, two, without longeing, recovers in tierce, leaving his body exposed, bringing the right foot up to the left ankle, left hand down to the side.

Disengaging Carte and Tierce.—Being your own turn to thrust, your opponent asks you to do so. Begin by bringing the foil in front of your adversary's body, arm quite straight, longe in carte within one inch of his chest, recover and both go through the salute as before; engage in carte. Make three disengages on each side as before, finishing in carte, each beat twice with the right foot, bring the right foot up directly to the left ankle, take one pace backward with the left foot, resting the pommel of the foil on the right knee, the foil perpendicular, body upright; beat twice again, bring the left foot up to the right heel, right hand under the chin, go through the salute again, finish by describing a circle with both hands, resting the right hand on the knee; beat twice with the right foot, bring the right foot up to the left ankle, hand under the chin, and drop it to the right side over the knee, left hand down, after which put the mask on.

The Assault.—An assault with foils resembles an encounter with small-swords. All the thrusts and parries learned in the lesson should be brought into play, the object of each fencer being to discover the intentions of his adversary and conceal his own. Never fence without having a mask on, also a jacket of leather or some strong material to prevent accident; also see that the foils are properly buttoned. When you put yourself on guard, endeavor to discover whether your opponent has a mind to attack or defend; for this purpose, take one step backward, showing your point opposite his chest; if he thrusts, parry carte by giving a beat on his foil; if engaged in tierce, parry tierce; should he make the feint of one, two, take the counter of carte; and so on. Try not to let your adversary know your intention by your eye; keep changing to avoid this advantage which you may give him. Never throw the head forward in longeing: by so doing you cannot recover quickly. Always take care to be covered in whatever side you are engaged: if in carte, cover the body to the inside; if in tierce, cover the body outside; observe the same rule in the low guards.

The Double Counters.—Engaged in carte, disengage to tierce, straightening the arm without longeing. If your adversary takes the guard of counter-carte, disengage again; should he take the counter a second time, double, following his foil, longe in tierce; for instance, by doubling counter-tierce, you deceive with a circle your opponent's counter-carte. Engaged in tierce, disengage to carte; straightening your arm, point to your opponent's chest, but be careful not to expose your body by inclining it forward; this should always be avoided. As soon as he takes the counter of tierce, double, and longe in carte; the same rule is to be observed in the lower guards; that is, if you are engaged in half-circle, disengage to octave; if your adversary takes the counter of half-circle, double and longe in octave, engage in octave, disengage to half-circle; if he takes the counter of octave or seconde, double circle and longe in half-circle or carte.

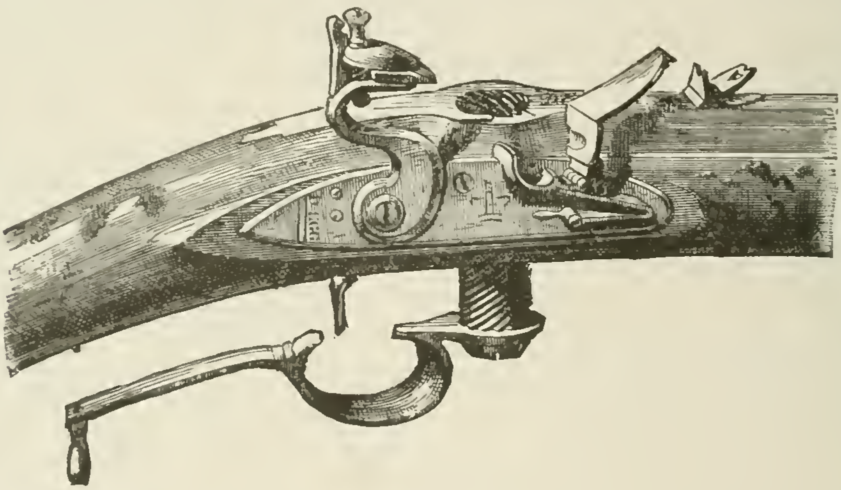
To Guard the Double Counters.—After having taken the counter-guard twice, not meeting with the foil of your adversary, take the simple guard on the opposite side; for example, being deceived in your double guard of counter-carte, take the simple guard of tierce or half-circle; being deceived in your double guard of counter-tierce, take the simple guard of carte; the same for the low guards. Being deceived in your double circle, take the guard of octave; being deceived in your double of octave or seconde, take the guard of half-circle or tierce, always continuing the guard until you meet with the adversary's foil. Another way of stopping the double movements is to take the guards of counter-carte and counter-tierce, or counter-tierce and counter-carte, without stopping; for the lower part of the body, take the guards of counter-circle and counter-octave, or counter-octave and counter-circle. This is an excellent practice to strengthen the wrist and make it supple.

In an article limited in length as this must necessarily be, it is impossible to give more than the merest outline of the various motions; but of course in actual practice there are endless variations of the different modes of attack and defense, which will be severally adopted according to the skill and option of the fencer. There is no finer indoor exercise than fencing, as the muscles in every limb are developed and strengthened by it. The great requirements for success are a steady eye and hand; a quick purpose, as quickly executed; and perhaps, above all, perfect equanimity of the temper. See *Bayonet-exercise* and *Sword-exercise*.

FENIAN SOCIETY.—A political association of Irish or Irish-Americans, the object of which is the overthrow of the English authority in Ireland and the establishment of a Republic. The etymology of the name has been the subject of some discussion. It is traced to the ancient Irish military organization called Fionna Eirinn, which took its appellation from the celebrated hero of Irish legend, Finn (or Fionn) MacCumhail. The accounts of this renowned body, with which the bardic literature of Ireland abounds, are most curious. It was designed as a National Militia, and its origin is ascribed, by Keating, to Sedna II., who was Monarch of Ireland about 400 years B.C. In time of peace it consisted of three bodies, each formed on the model of a Roman Legion, and consisting of 3000 men; but in war it was capable of being enlarged to any required limit. Candidates for enrollment were required to be of honorable family, to be irreproachable in morals, and to bind themselves to observe the laws of justice and morality; they were required to be of a certain height, and strong, supple, and vigorous of body; each being submitted, before enrollment, to an ordeal, in which his powers of speed, strength, endurance, and courage were tested by trial with his future comrades. The bardic accounts of some of those conditions are extravagant and amusing in the highest degree, but the generally historical character of the institution is unquestionable; and it subsisted until the reign of Carbry, son of Cormac MacArt, by whom the body of Fionna Eirinn was disbanded, and the members having, in consequence, transferred their allegiance to Mocorb, King of Munster, suffered an almost total extermination in the battle of Gavra, 284 A.D., which formed the theme of many a bardic poem from the days of Oisin (known in Gaelic legend as Ossian), son of Finn MacCumhail, downwards.

Adopting the name of this ancient military association, the modern Fenians (or Finians) are a secret association for the purpose of overthrowing the alien ascendency of the Saxon, and of restoring to the ancient Celtic population their legitimate status and influence in their native country. It had its first seat in America, where the Irish population has largely increased since the famine of 1846–47. Many of the emigrants being driven from their homes by arbitrary ejectment, or from inability to pay rent, carried with them a sense of fancied wrong, which prepared them for almost any enterprise which seemed to promise revenge. Others had been sympathizers, if not participators in the insurrection of 1848; and almost all were deeply imbued with general political and social discontent. By all these the prospect of a secret organization for the establishment of Irish independence was eagerly accepted. The most openly active seat of the organization was in the Western States, especially Chicago; but the movement was directed from New York, and it possessed ramifications in almost every old city of the Union. It was conducted by a Senate, and consisted of "Circles," each directed by a Center. The duty of the Centers was to enroll members, who bound themselves, generally by oath, "to be faithful to the Irish Republic as at present virtually established"; to instruct and practice them in military exercises; to raise funds for the purposes of the association, especially for the purchase of arms and munitions of war; and to extend the organization by every means at their disposal. Agents were sent into Ireland, and to the chief seats of the Irish population in England; and while the work of secret enrollment was industriously carried on in Ireland, measures were openly concerted in America, as well for the raising of funds by private contributions, as for the purchase of arms and military stores. Opportunely, too, for the purposes of the enterprise, the termination of the Civil War in America set free a large number of military adventurers who had served as privates or as officers in one or other of the American armies, and whose experience of service was turned secretly but most actively to account in the training of the young recruits enrolled in the Fenian Conspiracy in Ireland. Newspapers, moreover, both in America and in Ireland, were established or subsidized for the purposes of the Conspiracy; and journals, broadsides, ballads, and other inflammatory publications were largely circulated among the peasantry and artisans. Taverns, alehouses, and other places of entertainment were the ordinary places of meeting; and one of the most formidable of the plans of the Conspiracy was an organized attempt to seduce the Irish soldiers from their allegiance, and to prepare the way for their deserting to the ranks of Fenianism when it should have reached the expected degree of maturity. It became apparent, moreover, that in this, unlike almost all similar movements, pains were taken by the organizers to exclude the Catholic Clergy, by whom the Fenian Confederation had from the first been steadily resisted, from all knowledge of its character and objects, as well as of the names or number of its members in the several localities; and many of the most active of the leaders were distinguished by the freedom of their religious opinions, and by their unconcealed disregard of clerical authority.

FER.—A word figuratively used for a sword or a dagger; as in the phrase *manier le fer*, to wear the sword, to follow the profession of arms.



Ferguson Rifle.

FER A CHEVAL.—In fortification, a horseshoe, a small round or oval work, with a parapet, generally made in a ditch or in a marsh. It further means, according to the French acceptation of the term, a work constructed for the purpose of covering a gate, by having within it a guard-house, to prevent the town from being taken by surprise.

FERDWIT.—In the ancient military history, a term used to denote the freedom from serving upon any military expedition, or, according to some, the being acquitted of manslaughter committed in the army.

FERENTARII.—Among the Romans, the auxiliary troops lightly armed; their weapons being a sword, arrows, and a sling. We have also mention of another sort of Ferentarii, whose business was to carry arms after the army, and to be ready to supply the soldiers therewith in battle.

FERGUSON RIFLE.—A curious breech-loader used early in the Revolutionary War. Major Ferguson, a British officer, was authorized to arm and drill his troops according to his own ideas; and if tradition and circumstantial evidence are to be relied on, it was his purpose to place in their hands a *breech-loading rifle* with a variety of improvements, considered of recent date. Some of these rifles were used in the battle of King's Mountain, 7th October, 1780, the turning point of the war at the South,—as Oriskany, another riflemen's fight, 6th August, 1777, had been at the North,—a battle in which he was defeated and slain. Although a breech-loader not of American invention, it has become American from the fact that it made its first appearance as a weapon of war on the battle-fields of America, and is the first instance of a breech-loading rifle ever having been used on this Continent or any other. The arm has been photographed and engraved. Referring to the drawing, a few details will serve to explain its peculiarities. The length of the piece itself is 50 inches, weight 7½ pounds. The bayonet is 25 inches in length and 1¼ inch wide, and is what is commonly called a sword-blade bayonet; flat, lithe yet strong, of fine temper and capable of receiving a razor edge, and, when unfixed, as serviceable as the best balanced cut-and-thrust sword. The sight at the breech is so arranged that by elevating it is equally adapted to ranges varying from one hundred to five hundred yards. Its greatest curiosity is the arrangement for the loading at the breech. The guard-plate which protects the trigger is held in its position by a spring at the end nearest the butt. Released from this spring and thrown around by the front, so as to make a complete revolution, a plug descends from the barrel, leaving a cavity in the upper side of the barrel sufficient for the insertion of a ball and cartridge or loose charge. This plug is an accelerating-screw, and is furnished with twelve threads to the inch, thereby enabling it, by the one revolution, to open or close the orifice; so that the rifle is thereby rendered capable of being discharged, it has been claimed, as rapidly as Hall's United States (flintlock) carbine. This accelerating-screw constitutes the breech of the piece, only instead of being horizontal, as is usually the case, it is vertical. Were there not twelve independent threads to this screw, it would require two or three revolutions to close the orifice; whereas one suffices. Many of the muskets fabricated in the French arsenals during the last years of Napoleon had bayonets of the shape mentioned herein adapted to them, specimens of which were deposited among the French trophies in the Tower of London. In case of any injury to the fire-arm, the sword-blade bayonet would have been as effective a weapon as the artillery or even the infantry sword carried by foreign troops.

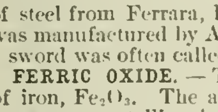
FERRARA.—A sword of excellent temper, made of steel from Ferrara, Italy. The kind most prized was manufactured by Andrea di Ferrara; hence such a sword was often called an Andrea-Ferrara.

FERRIC OXIDE.—The peroxide or sesquioxide of iron, Fe_2O_3. The anhydrous peroxide, as found in nature, crystallizes in flattened, rhomboidal tablets, nearly black and very brilliant, known to mineralogists as "specular iron;" it also occurs in compact red masses, called "red hematite." Prepared artificially, by calcining ferric protosulphate, or copperas, it is a red powder, called colcothar, used as a paint, and for polishing silver and mirrors. Magnetic iron-ore is commonly held to be a compound of ferric oxide and ferrous oxide, $Fe_2O_3 + FeO = Fe_3O_4$.

FESS.—The Fess in Heraldry consists of lines drawn horizontally across the shield, and containing the third part of it, between the honor point and the nombril. It is one of the honorable ordinaries, and is supposed to represent the waist-belt or girdle of honor, which was one of the insignia of knighthood.

PER FESS.—A shield, or charge in a shield, is said to be *party per fess* when it is horizontally divided through the middle, or, as the French say, simply *coupé*.

FESSWISE is said of a charge placed *in fess;* that is to say, horizontally across the shield. See *Heraldry*.



Fetlocks.

FETLOCK—FETTERLOCK. English heralds speak of a horse fetlock or horse fetterlock, and represent it as in the two accompanying figures. It seems to have been an instrument fixed on the leg of a horse when put to pasture, to prevent his running off. In Scotch Heraldry, a hoop is usually substituted for the chain, and the fetlock is represented as in the arms of Lokkert (Lockhart) of Barre, given by Sir David Lindsay: Argent, on a bend sable three fetterlocks *or*. Some branches of this family carry a man's heart within the fetterlock, one of the heads of it having accompanied good Sir James Douglas with King Robert the Bruce's heart to the city of Jerusalem.

FETTER.—To put fetters upon, or confine the feet with a chain. Deserters are frequently fettered while undergoing punishment for the crime of desertion.

FEUD.—Another form of the word *fight*, and is allied to *foe*, and probably to *fiend*. It meant a war waged by one family or small tribe on another, to avenge the death or other injury of one of its members. In a certain state of society this is a legitimate mode of obtaining redress. It prevailed extensively among the nations of Northern Europe; and it was only by gradual steps that the practice was first restricted and then abolished. The laws of Rudolf I. of Germany recognized the right of waging feuds. At last partial associations were formed, the members of which bound themselves mutually to settle their differences by Courts of Arbitration and Compensation, without going to war.

FEUDAL.—Consisting of, or founded upon, feuds or fiefs; embracing tenures by military system; as, the feudal system. By some, the word *feu* or *feud*, of which *feudal* is the adjective, is derived from the Latin *fides*, faith, and *ead* or *odh*, or *od*, a Teutonic word signifying a property, or estate, in land; whilst by others, with perhaps greater probability, the first syllable also is maintained to be Teutonic, equivalent to *rich*, cattle, ultimately from the same root with the Latin *pecus*, which, in the form of pecunia, came to signify property, and its representative, money—because, as Varro remarks, property amongst pastoral nations consisted of cattle.

FEU DE JOIE.—A discharge of musketry into the air, made in honor of a victory or other great occasion. It commences with the right-hand man of the line, who discharges his rifle, and is followed successively, at scarcely perceptible intervals, by the men on his left, until the extreme left of the line is reached. The effect much depends on the regularity with which the slight interval between the discharges is preserved.

FEU RASANT.—A grazing fire, or a discharge of musketry or cannon, so directed that the balls shall run parallel with the ground they fly over, within 3 or 4 feet of the surface.

FEVER.—In veterinary practice a disease characterized by increased heat, quick pulse, and thirst. In horses it is caused by cold or chill, high feeding, irritation, or pain. The symptoms are lassitude, shivering, quick pulse, and breathing after feed. The cure consists in bleeding, and keeping open the bowels by clysters and laxative medicine. The animal's body and extremities should be kept warm by clothing and hard rubbing; the diet green meat, or bran mashes, chilled water; and the horse should be kept as quiet as possible.

FEZ.—A red cap without a brim, commonly worn by the Turkish soldiers and others.

FICHANT.—In fortification, a term applied to flanking fire which impinges on the face it defends; that is, of a line of defense where the angle of defense is less than a right angle. A fortification is said to be *fichant* when the command is very great.

FID.—1. A block of wood used in heavy-gun exercise, for slinging the gun, and for mounting and dismounting purposes. The latest pattern of fid is of beech or elm, and each is provided with a rope grummet, and has the nature of the gun for which it is intended stamped upon it.—2. A large pointed pin for splicing ropes, with an eye at the thick end, of iron or lignum vitæ, used by sailors in separating and interlacing the strands of which the rope is composed.

FIEF.—An estate held of a superior on condition of military service; a fee; a feud.

FIELD.—1. A cleared space or plain where a battle is fought; also, the battle itself. *To take the field* means to commence active operations against the enemy.—2. In Heraldry, the field is the whole surface or continent of the escutcheon or shield. It is so called, according to some, because it represents the field of battle on which the achievements or charges represented on it are supposed to have been gained. In blazoning, the tincture or metal of the field must be the first thing mentioned.

FIELD-ALLOWANCE.—A daily allowance granted to officers of the British army in consideration of extra expense entailed upon them in consequence of military operations. *Ordinary* field-allowance, ranging from £1 10*s*. for a General Officer to 1*s*. for a Subaltern, is applicable when troops are encamped at home or in the Colonies. *Extraordinary* field-allowance is sanctioned when and wherever troops are engaged in actual warfare: it ranges for the above ranks from £2 10*s*. to 1*s*. 6*d*. Strict rules are laid down that no officer shall receive this allowance unless positively present with the army.

In India there is no such allowance, as the pay which officers receive is considered sufficient to enable them to keep up their camp equipage, and to meet all expenses attendant upon a move from cantonments or in setting out on a campaign. See *Allowances*.

FIELD AND MOUNTAIN AMMUNITION.—The ammunition for field and mountain service in the United States service consists of—*shot* for the 12-pounder gun; *shells* for the 12-pounder gun, 12-pounder mountain-howitzer, and 3- and 3½-inch rifle-guns; *case-shot* for the 12-pounder gun, 12-pounder mountain-howitzer, and 3- and 3½-inch rifle-guns; *canister* for the 12-pounder gun, 12-pounder mountain-howitzer, and 3- and 3½-inch rifle-guns. The projectiles are attached by straps of tin to a wooden sabot, to which is also fastened the *cartridge-bag* containing the charge for the 12-pounder and the mountain-howitzer, making together one round of fixed ammunition. With rifle-guns the cartridge is not attached to the projectile. The cartridge-bag is a cylindrical bag with a circular bottom, made of merino or serge. The material should be composed entirely of wool, free from any mixture of thread or cotton, and of sufficiently close texture to prevent the powder from sifting through; that which is twilled is preferred. Flannel is used when the other materials cannot be conveniently obtained.

The manner of fixing and strapping ammunition is explained in the articles Fixed Ammunition and Strapped Ammunition. The following is the mode of charging shells for field and mountain service: The shells having been properly cleaned, dried, tapped to receive the plug and the fuse, and attached to the sabot, are placed in two rows. The workman fills the measure with powder, strikes it level with the straight-edge, and pours it in the shell; the assistant holds the funnel, and marks the shell with chalk when filled, to prevent mistakes. The assistant screws in the plug. The workman puts a little white-lead on the threads of the fuse, punches 4 or 5 small holes in the tin disk, and screws the fuse firmly into the shell, the assistant holding the shell to prevent it from turning.

In the matter of a case-shot, the shot having been cleaned and inspected, the upper part of the fuse-hole is tapped to receive the fuse; the small hole is tapped to receive the plug. The following materials are required to fill the shells: spherical leaden balls, caliber .69 inch; sulphur or rosin; linseed-oil. To fill the shell, cover the lead balls with linseed-oil, and fill the shell with them, pushing the upper balls aside with a stick, to get in as many as possible. Warm the shell gently, and screw the neck of the funnel into the fuse-hole; pour in the melted sulphur, filling the shell. To make the chamber for the charge, chuck the shot in a lathe; screw the funnel into the fuse-hole to protect the threads from being injured by the auger, and with a common screw-auger bore a hole in the axis of the shell to the bottom. Diameter of the auger, .75 inch. Lacker the shot and strap it; paint it red. To charge the shot, fill the chamber with musket-powder, ramming it slightly with a wooden drift and light mallet; screw in the iron plug, leaving its top flush with the bottom of the large portion of the fuse-hole, and lay over it a thin leather washer with a hole in the center; fill the hole in the plug and washer with rifle-powder; punch four or five small holes in the tin disk in the bottom of the fuse; put a little white-lead on the threads of the fuse, and screw the fuse firmly into the shell. The case-shot is fixed the same as round shot.

A canister for field-service consists of a tin cylinder attached to a sabot, and filled with lead balls, eleven to the pound. Canister for the mountain-howitzer are filled with lead balls. The following materials are required: sheets of tin, .02 inch to .025 inch thick (double tin); soft solder; rosin; culots of rolled iron, .25 inch thick; covers of sheet-iron, .07 inch thick for the guns and 12-pounder howitzers, and .1 inch thick for the 24- and 32-pounder howitzers; sabots; tacks.

Canister for rifle-guns have metal sabots, and are filled with lead balls. The following utensils are required: patterns; tracing-point; shears; cylinder of hard wood; mallet; gauges; furnace; soldering-iron; hammer; punch. To make the cylinder, the workman marks out the rectangle on the sheet with the pattern, cuts it, and traces the line for the lap. He draws a line parallel to the long side of the rectangle, .4 to .5 inch from it, for the length of the slits. It is then bent round the former, the edge brought to the line of the lap, clamped and soldered. If lumps of solder be left, they are filed down. The cylinder is made round and gauged on the exterior with the large shot-gauge of the caliber, and the interior with a cylinder of a diameter .02 inch less than that given in the table, which should enter the canister. If it be not of the right size, it is unsoldered and soldered over again. The slits are made and the sabot inserted and nailed with 6 to 8 nails. Before filling the canister, dip the tin cylinder into a lacker of beeswax dissolved in spirits of turpentine, to prevent it from rusting. Coat the plates with paint or coal-tar.

The workman, sitting astride the bench, places the canister upright in front of him; inserts the iron bottom and places it flat on the sabot; puts in a tier of balls; fills the interstices with dry, sifted sawdust; packs it with a pointed stick, so that the balls will hold by themselves, and throws out the loose sawdust. He places another tier of balls, each ball lying in the interval between two balls of the lower tier, and proceeds in the same manner until the canister is filled; covers the upper tier with sawdust; puts on the cover, places on it one of the iron bottoms furnished with a handle, and strikes it with a small mallet in order to compress the sawdust; then removes this bottom, and turns down the slit pieces of the canister over the cover with a hammer. In the canister for the 12-pounder gun the center ball of the last tier is omitted. When the canister is finished, verify its diameter with the large shot-gauge of the same caliber.

The Sawyer canister-shot for all guns and howitzers consists of a casing of malleable iron, in one piece, in the form of a hollow cylinder, having one end closed by a head cast therewith, through which head is formed one or more small holes, through which a portion of the gas occasioned by the explosion of the charge of powder enters, driving forward the small iron balls, and disengaging the metal cover placed in the forward end of the casing to hold the contents in position till fired. The casing has, cut through its walls, one or more series of oblique slits, the end of each slit slightly overlapping the end of the next slit in the same series, thus nearly severing the casing into two or more sections, said sections being held together only by narrow bars of metal between the contiguous ends of two slits, which bars are sufficiently strong to withstand the ordinary shocks of handling and transportation, but not strong enough to resist the shock of the explosion of the charge of powder in the gun, so that when the shot is discharged from a gun the cover is stripped from the mouth of the casing, and the casing is broken into two or more sections, from which the small shot are more readily and completely discharged than they would be if the casing remained intact.

SUMMARY OF THE AMMUNITION FOR FIELD AND MOUNTAIN SERVICE.

		Smooth-bore gun.				Howitzer.			Rifle-guns.						Hotchkiss.	
		12-pounder, bronze.				12-pounder mountain-howitzer.			3-inch iron.			3.5-inch iron.			Revolving cannon.

For the greater security of field-ammunition, the cartridges are covered with paper cylinders and caps. The cap is drawn off at the moment of loading the piece, and in using solid shot it may be placed over the shot to diminish the windage. A cylinder and a cap are formed together by folding the paper over a former, which allows a lap of about .75 inch for pasting. The requisite length for the cylinder is cut off from the smaller end. The rest forms the cap, which is choked at the end from which the cylinder is cut on a cylindrical former, which has a groove around it, marking the length from the rounded end for cutting the cap. The former should be bored through the axis with a .5-inch hole, to facilitate drawing off the cap. The caps for shells are black; for spherical case-shot, red; for shot, not colored.

On the preceding page will be found a summary of the ammunition for field and mountain service.

Shells are filled with the bursting-charge of mortar-powder to their capacity. Case-shot are filled with lead balls which are set with melted sulphur or rosin, and bored out for the bursting-charge with as large a chamber as the fuse-hole will admit of, which is filled with powder or bursting-charge of other explosive, space being left for the fuse-plug or fuses. When sabots are used, a spherical cavity is made for the seat of the projectile. When port-fires are used, one to each box of ammunition, and half a yard of slow-match is packed, and sufficient tow to render the whole packing secure. Large charge for 3-inch rifle-gun, 1.5 pound; half an inch is allowed for each seam in a cartridge-bag. Rifle-ammunition has no wooden sabots, nor is the cartridge attached to the projectile; these are packed on top of the projectiles, or, better, in a part of the box separated from the projectiles by a partition, in which case the small stores are packed on top of the cartridges. Hotchkiss ammunition is metallic; wrapped metal; centre-primed case. See *Ammunition*, *Ammunition-boxes*, *Cartridge-bags*, *Fixed Ammunition*, *Projectiles*, *Sabot*, and *Strapped Ammunition*.

FIELD-ARTILLERY.—Field-cannon are intended to be used in the operations of an army in the field; they should, therefore, have the essential quality of mobility. They are divided into light and heavy pieces. The former are constructed to follow the rapid movements of light troops and cavalry. The latter are employed to follow the movements of heavy troops, to commence an action at long distance, to defend field-works and important positions on the field of battle, etc.; hence they are said to constitute "batteries of position." Formerly the light pieces of the field-service of the United States were the 6-pdr. gun and 12-pdr. howitzer; and the heavy pieces were the 12-pdr. gun and 24-pdr. and 32-pdr. howitzers. At the commencement of the late war in this country, these pieces were set aside for arming field-works, block-houses, etc., and their places were supplied with the light 12-pdr. gun (smooth-bore) and the 3-inch rifle-gun. The regulations prescribe that, as a general rule, one third of the pieces of a field-battery be rifles and the remainder smooth-bores. Of course this proportion is subject to be modified by the character of the operations and the nature of the country. The country in which most of our late military operations were conducted was either broken in surface or heavily wooded, and the most effective fighting was done at moderate ranges, at which the light 12-pdr., with its heavy shell and case-shot, was found more destructive than the 3-inch rifle-gun.

Field-artillery is used in combination with infantry and cavalry, or with both, to augment their fire and to weaken that of the enemy. It prepares the way for subsequent operations by its fire upon the enemy before he comes within reach of other weapons; it supports the maneuvers of the various arms, and forms points of support and assembly for troops when driven back. In selecting the position for a battery, the ground must be considered both in plan and profile. The guns must be placed neither too high nor too low. Late wars have shown that it is not alone desirable but necessary to cover the guns and horses of a battery from the enemy's fire, either by the accidents of the ground or by improvised cover; for nothing else can insure the battery against destruction by the enemy's infantry and artillery. The range, accuracy, and rapidity of fire of small-arms of the present day are such that batteries which have been brought into action with the greatest possible rapidity have been placed *hors du combat* before firing a shot. The most favorable position is a gentle hillock, sloping gradually to the front and more abruptly to the rear, with a command over the ground occupied by the enemy of about 1 in 100. Considering the ground in plan, guns may be drawn up with good effect behind a marsh, pond, or river or ravine, provided such obstacles do not render an advance impracticable, and the ravine be not occupied by the enemy. The guns should not be in the neighborhood of woods, brush, or other cover that can be occupied by the enemy. Heavy, muddy ground, as well as that which is stony, should be avoided. The ground for 50 to 100 yards in front of the battery should be as unfavorable as possible for the enemy's artillery-fire.

The *extreme range* should be employed only when the nature of the ground or the shortness of the time does not permit a nearer approach to the object, and then only till the effect desired has been obtained. With rifled pieces this fire may exceed 5000 or 6000 yards. It may annoy troops in their camp, may impede the movement of trains, and endanger inflammable buildings and materials, but cannot affect an action; therefore, to open fire beyond the limit at which the effect can be ascertained by good sight, aided by telescopes, is a waste of valuable ammunition. If the ground and atmosphere be favorable, and the range can be determined accurately, fire may be opened against troops at 2500 yards, and under exceptional circumstances at 3000 yards; the former is about the distance at which bodies of troops can be distinguished with certainty by the best eye. This distance is modified by the formation of the troops; a column can be fired at effectively 500 yards beyond troops in line. At long range the object must be well defined, the distance carefully determined, and the firing calm and very deliberate. As a battery cannot withstand the fire of small-arms, artillery without cover cannot now maintain a position within 900 yards of the enemy's infantry.

The object selected upon which to direct the fire depends upon the nature of the action. In acting offensively, the fire should be concentrated on the enemy's artillery and on obstacles which oppose an advance; whilst if acting defensively, the guns should bear upon the infantry and cavalry. As a general principle, the fire should be directed upon that arm of the enemy which most immediately threatens us. Definite rules cannot be given for what must practically be decided almost entirely by the peculiar circumstances of the individual case. The nature and position of the object fired at determine the projectile to be used. The employment of solid shot is growing greatly into disuse; with rifled guns it is but little used, and in many services is entirely discarded, as the shell and shrapnel as now constructed are sufficiently strong and heavy to replace it and produce far more ultimate effect. It may be useful in firing over troops, but even then shells, preferably with percussion-fuse, can be employed. Shells are used at first to determine the range; for this, percussion-fuses are best if the nature of the ground permit. This fire is used to disable artillery; against columns of troops, or when a line can be enfiladed or taken obliquely; against obstacles, such as intrenchments and buildings, and against combustible materials. If the shell be intended for incendiary purposes, a time-fuse cut long is employed. Should the distance be accurately known and the time-fuse burn uniformly, such a fuse can be advantageously used; but generally a percussion-fuse is more useful. The nature of the ground is of importance only at the spot where the shell strikes; there it should be firm enough to cause a percussion-fuse to act and to prevent the shell from penetrating so far as to lose its explosive effect. Shell-fire is employed when the enemy is posted under cover, or on a higher or lower ground; when he is moving on a road through a valley, and when being pursued; when the ground is much broken, wooded, or cannot be seen; when the range is too great for effective shrapnel fire; for incendiary purposes, and when a moral rather than a physical effect is desired.

In the fire of shrapnel and segment shells, it is of more importance to have a knowledge of the distance than of the nature of the ground, as the elevation must be properly taken and the fuse correctly timed. If such a projectile explode after passing the object, its effect is entirely lost; and if it explode too far short, the effect is greatly diminished; therefore the aim should be taken a little short of the object, that it may be the more readily corrected. The spread of the pieces being greater in the direction of the fire than laterally, these projectiles are more effective against high, deep objects than against broad, flat ones; they are therefore more destructive against cavalry in column than in line, and more so against either than against infantry in column or in line. Shrapnel-fire is also employed against troops dispersed or scattered; against troops in defiles or openings, or massed at points. It is effective against artillery in position, especially when it can be taken obliquely; time-fuses should be used against the animate objects, and percussion-fuses against the *matériel*. Time- or percussion-fuses can be employed against troops in column or in line; but if they be scattered, time-fuses only should be used. Well-applied shrapnel-fire is more effective than any other artillery-fire against troops, but it is subject to so many contingencies, and the ammunition is so costly, that it should not be employed unless it will probably create considerable effect, and when other projectiles will not answer. The possibility of shrapnel exploding in the piece causes great care to be necessary in firing over the heads or through the intervals of the troops. The fire of canister-shot is confined to ranges within 500 yards, and is rarely of any effect beyond 350 yards. The nature of the surface has a great influence on the utility of this fire; it is largely diminished on rough or soft ground, especially if covered with bushes or standing crops, and is increased on hard, level ground. As batteries can no longer move up to short range of troops and open fire with canister, its use offensively is entirely ended. On the defense, it is used to most advantage against troops in column whose front is greater than thirty or forty feet; it is useful against scattered or dispersed troops at short ranges, and against the attack of field-intrenchments, villages, and the skirts of woods. In cases of great emergency, a double charge of canister, fired with a single cartridge, may be used for distances within two hundred yards. A canister-fire should not be used too early, as, if ineffective, it destroys the confidence of the troops and increases that of the enemy. It does not always produce the desired effect: 1st, because the distance is underestimated; 2d, sufficient care is not taken in aiming, because the danger is exaggerated; 3d, the character of the ground is not properly appreciated and projectiles are wasted. The fire of machine-guns, which can be used effectively at 1500 yards, may replace the employment of canister.

The selection of the most suitable kind of fire, whether direct or ricochet, depends upon the distance of the enemy, the conformation and nature of the intervening ground, the formation of the troops, so far as it can be judged, and the effect to be produced. Direct fire should be employed whenever the surface of the ground is uneven and the quality of the soil varied, or the soil soft and light. It is used in special cases: 1st. When the enemy is so situated as to conceal the depth of his formation. 2d. When he is about to pass a defile, and the head of the column only is seen, or when the depth of the column can be seen by being commanded or overlooked. 3d. In all sustained cannonades. 4th. If the enemy be on a mountain or in a valley. When the difference of level between the object and piece is not great, the character of the fire will be determined by the nature of the intervening ground. Ricochet-fire should never be used for a less distance than 1000 yards, even when the ground is favorable, as it is necessary that the projectile should make at least two or three rebounds in front of the enemy. For the 12-pounder gun the limits of this fire may be considered as between 1200 and 1500 yards; the extreme range extending, however, to 2000 yards: for a less distance the rebounds are too high and the space commanded too small. If the ground be uneven, ricochet-fire will be too irregular to be useful. An open, flat, and firm piece of ground is most favorable; if within a certain distance in front of the piece or of the enemy the ground be soft and uneven, this species of fire cannot be employed. As much depends upon chance in ricochet-fire, it is seldom used on the offensive, for it attracts the attention of the enemy without doing much execution. See *Artillery*, *Napoleon Gun*, *Ordnance*, and *Three-inch Rifle*.

FIELD-ARTILLERY FUSE.—The name given to the Breithaupt fuse by its inventor, because he designed it for all kinds of shells used with field artillery. See *Breithaupt Fuse*.

FIELD-BATTERY.—A certain number of pieces of artillery so equipped as to be available for attack or defense, and capable of accompanying cavalry or infantry in all their movements in the field. There are usually allotted to a field-battery four pieces in time of peace and six in time of war, and it is divided into *mounted artillery*, which usually serves with infantry, and *horse-artillery*, which ordinarily serves with cavalry. The main difference between the two consists in the cannoneers of the latter being mounted; in rapid evolutions of the former they are conveyed on the gun-carriages. See *Artillery* and *Battery*.

FIELD-BED.—A folding-bed used by officers while on campaigns or in the field. See *Camp-bedstead*.

FIELD-CARRIAGES.—A marked change has been made within the last few years in the fabrication of carriages for field and mountain artillery. The principal nations have arrived in quick succession at the same conclusion with reference to the material of which these carriages should be made, and have already abandoned the use of wood except for the spokes and felloes of the wheels, and for poles, and substituted in its place wrought-iron or steel. The consideration which has led to this important modification is the superior strength, serviceability, and ultimate economy of the wrought-iron carriage. The general plan of construction adopted is much the same in all countries, and the carriages differ only in minor details, which vary according to the different ideas of taste and convenience, or as influenced by long-established usage.

The cheek and side of the trail are formed of one piece of boiler-plate, cut into the required shape and strengthened by angle-iron riveted to it around its outer edge, or made in one piece in a die, with the flange struck up while the metal is hot. The two pieces constituting the trail are joined together by the necessary transom and bolts, and by the lunette, which is riveted to both. The trail is further strengthened by the transoms forming the two ends of the trail tool-chest. The two pieces which form the sides of the trail slope from the head of the cheeks or from a point a short distance in rear of it to the lunette, and at the same time diminish in depth. The angle-iron which is riveted to the cheeks to strengthen and stiffen them forms also the trunnion-beds, and is placed sometimes on the outside and sometimes on the inside of the plate. The elevating-screw is arranged differently in different services. Minor differences will be mentioned in describing the carriages in detail. The nomenclature is given in detail in the description of the carriages employed in the United States service.

United States.—There is a gun-carriage for the three-inch rifle, which with slight modifications is adapted to the one-inch mitrailleur; one for the half-inch mitrailleur; and one for the twelve-pounder. The corresponding parts of these carriages differ only in their dimensions. There are three kinds of wheels, viz.: No. 1, for the three-inch rifle and one-inch mitrailleur gun-carriages, for caissons, forges, battery-wagons, and all limbers except those of the half-inch mitrailleur; No. 2, for the twelve-pounder gun-carriages; No. 3, for the half-inch mitrailleur gun-carriages, caissons, and limbers. Wheels Nos. 1 and 2 are of the same form and height, fit on the same axle-arm, and differ only in the dimensions of their parts, strength, and weight. It is proposed that a single pattern of wheel be used hereafter for all light artillery-carriages except those for the half-inch mitrailleur.

Referring to Fig. 1, the nomenclature of the gun-

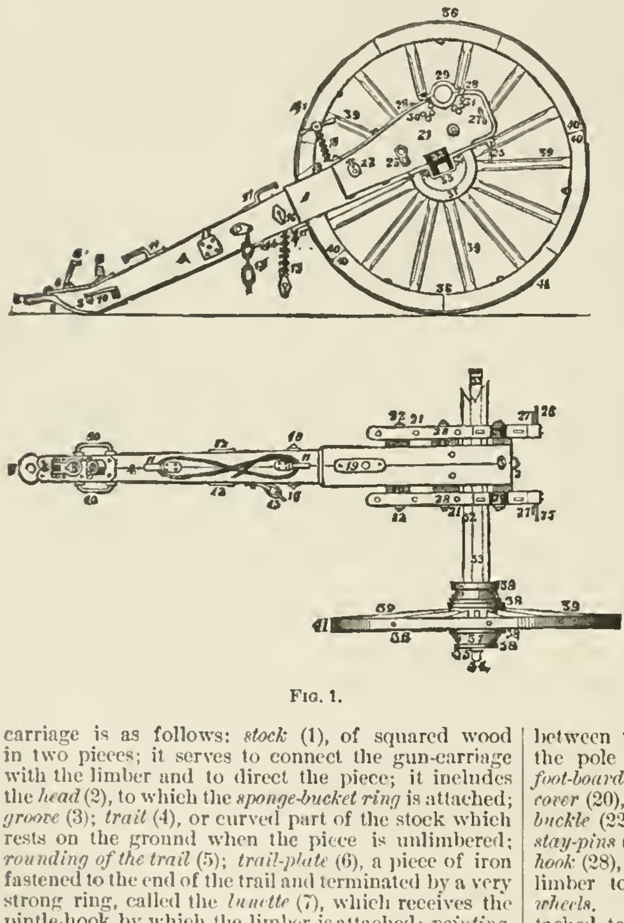

Fig. 1.

carriage is as follows: *stock* (1), of squared wood in two pieces; it serves to connect the gun-carriage with the limber and to direct the piece; it includes the *head* (2), to which the *sponge-bucket ring* is attached; *groove* (3); *trail* (4), or curved part of the stock which rests on the ground when the piece is unlimbered; *rounding of the trail* (5); *trail-plate* (6), a piece of iron fastened to the end of the trail and terminated by a very strong ring, called the *lunette* (7), which receives the pintle-hook by which the limber is attached; *pointing-rings*, large (8) and small (9), which receive the handspike; *trail-handles* (10), on each side of the stock for the purpose of raising it; *prolonge-hooks* (11), on which the prolonge is coiled; *wheel-guard plates* (12). *Lock-chain* (13), used to keep the wheel from turning; it is on the side of the carriage, and has an *eye-plate* and *bolt; sponge-and-rammer stop* (14); *sponge-chain* and *hasp* (15); *ear-plate* for sponge-chain and hasp (16); *ear-plate* to support worm (17); *key-chain* and *key; elevating-screw* (18); it has a *handle* with four prongs; *elevating-screw box; elevating-screw bed* (19); *rondelles* (20), which connect cheeks and stock; *cheeks* (21), two pieces of wood between which the gun rests; *washer-hooks* for handspike (22); *washer-hook* for lock-chain (23); *under-strap* (24); *right sponge-hook* (25); *sponge and worm hook* (26); *handspike-rings* (27); *trunnion-plates* (28), into the *beds*, or depressions, of which the trunnions fit; *cap-squares* (29); *cap-square chain* (30); *key-chain* and *key* (31). *Axle*, including *axle-body* (32), of wood; *axletree* (33), of iron; *axle-arm* (34), the rounded extremities of the axletree on which the wheels revolve; *linch-pin* (35); *linch-pin washer* and *hook*. *Wheels* (36); each includes—*nave* (37); *nave-bands* (38); *nave-box; spokes* (39); *felloes* (40); *tire* (41). *Cannoneers' seats*, on the axle between the cheeks and wheels; each consists of an iron *chair* supported on a *rectangular bar* inserted in a vertical iron *socket*, and resting on a strong steel *spring;* the socket is supported by two *brass braces* fastened to the axle by *axle-straps;* to an iron *cross-piece* at the top of the socket are attached two *iron braces* which help to support the iron *foot-rest* attached to the brass braces. The chair has *arms* and faces to the trail.

The following is the nomenclature of the gun-carriage for mitrailleurs: *stock; head; groove; trail; rounding of trail; trail-plate; lunette; pointing-ring; pointing-socket; trail-handles; wheel-guard plate; elevating-screw; elevating-screw box; elevating-screw bed; rondelles; cheeks; washer-hooks* for handspike; *under-straps; handspike-rings; cap-squares; cap-square chains; key-chains* and *keys; trunnion-beds; trunnion-swivel; trunnion-swivel friction-bed; frame for traversing-apparatus,* or *traversing-arm; traversing-fork; traversing-fork spring* (spiral); *traversing-fork handle; traversing-fork clamp-screw; traversing-fork case,* with slot for handle; *locking-bolt,* connected with traversing-fork by a *locking-lever; locking-bolt case; stock-seat;* with a *hinge* and *prop; drag-hooks; elevating-screw nut; elevating-nut handle; elevating-clamp screw; rod-case* and *keys; axle; wheels.*

All limbers (Fig. 2) are similar; the limber-chests of gun-carriages and caissons contain ammunition and implements; those of forges and battery-wagons contain tools and stores. The nomenclature is as follows: *pole* (1), including *pole-pad* (2); *pole-straps* (3), by which the pole is guided when the team is hitched; *pole-strap iron* (4); *pole-yoke* (5); *muff and collar* (6); *pole-yoke branches* (7), to which are attached *sliding-rings* (8); *splinter-bar* (9), to which the wheel-horses are hitched, by four *trace-hooks* (10); *end-bands* (11); *middle-bands; pole-prop* (12), including *socket, ferrule,* and *chain; hounds* (13), the pieces of wood, upon which the chests rest, connecting the axle-body with the splinter-bar; *forks* (14), pieces of wood, between the hounds, forming an opening in which the pole is placed; *fork-strap* (15); *foot-boards* (16); *foot-board brackets* (17); *chest* (18); *chest-handles* (19); *cover* (20), of wood; *cover-plate* (21), of copper; *turn-buckle* (22); *hasp* (23); *back-stay* (24); *front-stay* (25); *stay-pins* (26); *stay-pin keys* (27); *under-strap; pintle-hook* (28), on rear part of axletree, which attaches the limber to the carriage; *pintle-hook key* (29); *axle; wheels.* The four trace-hooks are sometimes attached to the ends of the *splinter-bar traces,* which are strong leather straps, parallel to the splinter-bar; each works over two *pulleys,* attached to the end and middle bands; the pulleys are wrought-iron disks, turning on vertical bolts, passing through the rounded ends of the bands, which project three inches beyond the splinter-bar.

All caissons have the same external form, and, except those for the ½-inch mitrailleur, the same dimensions. The caisson *body* (Fig. 3) consists of a frame, mounted on wheels, which carries two chests, a spare wheel, and other spare parts, tools, etc. The nomenclature of the caisson body is as follows: *stock* (1), or *middle-rail;* it has an iron *lunette* on its front end; *side-rails* (2); *front foot-board* (3); *rear foot-board* (4); *middle-chest* (5); *rear-chest* (6); *spare-wheel axle* (7); it has a *body*, two *ribs*, and *chain and toggle* (8) to secure the wheel; there are also two *stays* for the axle; *lock-chains* (9), fastened to *lock-chain bridles* under the front ends of the side-rails, and held up by *lock-chain hooks* fastened to the outside of the side-rails; *spare pole* (10); *spare-pole key, key-plate, chain* and *pin* (11); the key-plate is fastened on the underside of the lunette; the key is attached to the left side of the stock by a *chain* and *eye-pin; carriage-hook* (12), for attaching a carriage that has lost its limber; *wheel-guard plates* (13); *spare-pole ring* (14), held by the axle-strap; *ring-bolt* (15) for spare handspike; *key-plate* and *key*, on the right side of the middle-rail; *key-plate, chain*, and *key* (16), for the shovel-handle, or the inside of the right side-rail; *middle assembling-bar* (17), of iron; it has two ears in the middle to serve as stay-plates for the middle chests, and a *slot* (18) for the axe on the right of the middle-rail; *rear assembling-bar* (19); it supports the spare-wheel axle, and has a *slot* (20) for the pickaxe on the left of the middle-rail. *Axle*, the *axle-body* (21) being notched to receive the middle rail and tenoned to fit into the notches in the side-rails; *staples* for *tool-handles* (22); they are driven into the top of the axle-body, in front of the iron axletree, one for the *shovel-handle* near the right side-rail, the other for the *handle of the pickaxe* on the left of the middle-rail. *Wheels.*

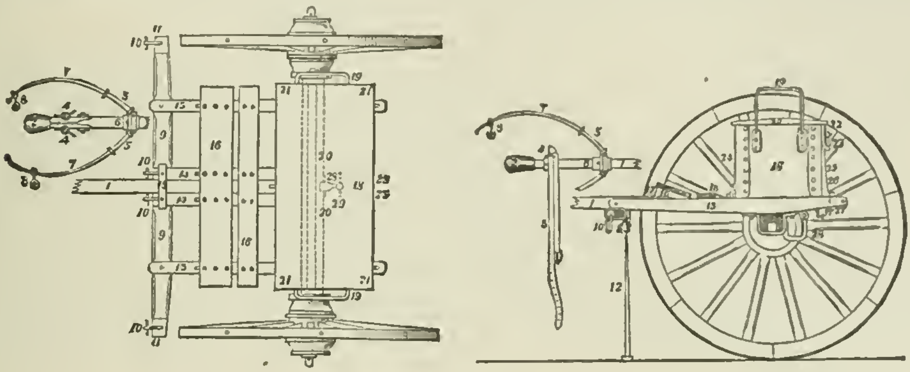

FIG. 2.

The Ordnance Department has recently made and tested certain wrought-iron field and siege carriages. The principal improvements aimed at in one of the patterns of field-carriages on the wooden carriages now in use are: 1. Lightness and cheapness. 2. Placing the pintle about two feet in rear of the limber axletree, so that the trail of the gun-carriage shall counterpoise the weight of the pole, and thereby relieve the shoulders of the wheel-horses which have now to support it. 3. Bringing the trunnion-beds nearer to the axletree, thereby diminishing the liability of overturning the carriage in traveling. 4. Allowing no part of the carriage to project below the plane of the axletrees. This is found necessary to prevent the breaking of the implement-fastenings in passing over stumps, stones, etc. 5. More convenient modes of carrying the rammers and trail handspike. 6. As the 12 pdr. carriage can be made of wrought-iron, so as to be little if any heavier than the wooden carriage used for mounting the 3-inch rifle-gun, but one carriage will be required for the field-service. In this case thimbles or washers will be required to fit the trunnions of the 3-inch gun into the trunnion-beds of the 12-pdr. carriage.

The very large stock of wooden carriages now on hand may delay, on the score of economy, the introduction of wrought-iron carriages for some time to come; but that such carriages can be made superior to wooden ones scarcely admits of doubt.

Austria.—The 3.42-inch gun-carriage (Fig. 4) is composed of two cheeks of sheet-steel .24 inch thick, re-enforced around the edge by an angle-iron .275 inch thick, the flange turned inward. The cheek-plates are parallel for a short distance in rear of the axle; from that point they converge to the end of the trail, where they are secured to the lunette. The cheek-plates are joined by two sheet-iron transoms toward the front end, and between them a cylindrical transom under the trunnion-beds; near the middle is a sheet-iron transom forming one end of the tool-chest; and the bolts passing through the principal irons. In order that the piece may not be too low, and to assure its having a sufficiently wide field of fire, the trunnion-beds have been raised considerably above the axle, and carried well forward.

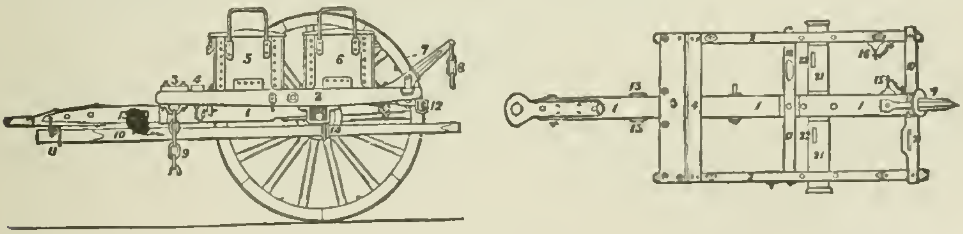

FIG. 3.

The axle is cylindrical, of steel, with shoulders for the cheeks, to which it is secured by solid bands and understraps. It is provided with two seats, like the Prussian carriage, and is braced to the trail by two rods just inside of the shoulder-washer.

The elevating-screw is composed of two screws, one within the other. The outer one, which works in a fixed nut between the cheeks, has a rim-handle for turning it. The head of the inner screw is hinged to two iron rods secured to the cheeks. The trail-handspike is secured to the socket, which is hinged to the support, so that the handspike can be turned down on the trail when it has been disengaged from the pointing-ring. The wheels have metallic naves, and are smaller than those in the United States service; they are only 52.75 inches in diameter. Two shoes are used for locking the wheel, and for checking the recoil in firing.

The limber is composed of two trough-beams, 3.5 inches by 2 inches by .2 inch, secured directly to the axle by understraps, and bent at the front so as to form the fork; a transom and a socket for the pole joins them in front; they are connected in rear by an iron bar placed on top, which supports the end of a double T-piece of iron, 2.75 inches by 2.36 inches, the web 1.57 inch; this piece carries the pintle-hook. The splinter-bar is round, hollow, fastened under the fork by understraps, and secured to the axle by iron rods. The distance of the pintle-hook from the axle is considerably greater than is necessary to balance the pole, it would seem, and increases the weight of the limber. The pole is of wood, and can be readily taken out or put in place.

The ammunition-chests are of sheet-steel .34 inch thick, and are divided by a principal vertical partition into two parts. Each part is in turn divided into six compartments by sheets of iron joined together, and strengthened by angle-irons at their junctions. The projectiles are packed in light wooden boxes, with cleats to keep them in place; the cover is held closed by a simple hook, and a handle is secured to it for withdrawing the box. The cartridges are placed in the compartments without doors. The chests are closed by two doors, which swing down around horizontal hinges placed on the lower edge of the chest; they are secured by means of a double turn-buckle attached to the principal partition, and by hooks near the ends of the chest. The handles of the chest are joined by a leather strap, and the rear part of the cover has a network for holding knapsacks. Three cannoneers can be seated on the front part of the chest. The limber-chest carries 34 rounds, of which 10 are shrapnel and 4 canisters.

The construction of the caisson is similar to that of the limber. It is composed essentially of a stock formed of two channel-beams 3.5 inches high and .2 inch thick, and two side-rails, also channel-beams, 2.75 inches high and .2 inch thick, bent in front to meet the stock, and joined at the rear by an iron bar. The caisson is provided with a brake, the cross-piece of which is a piece of round pipe suspended by a hinge from the side-rails. The spare wheel is carried under the caisson in a horizontal position. The spare wheel-axle is attached to the stock by a hinge a little in front of the axle of the rear wheels; the wheel is lashed to the body of the caisson.

The ammunition-chest is constructed like that of the limber, but has double the capacity. It is made, we may say, like two limber-chests, placed one in rear of the other, and is closed by 4 doors, 2 in front and 2 in rear, opening around the lower horizontal edge of the chest. It contains 60 projectiles, 35 of which are double shells, 20 shrapnel, and 5 incendiary shells, with 64 cartridges of 3.3 pounds, and 32 cartridges of 1 pound for plunging fire. The cover of the chest is provided with a netting for carrying various articles. The advantages which result from this mode of construction of the chest and the arrangement of the doors are so obvious as to make it needless to point them out.

The weights of the parts are as follows:

	Pounds.
Carriage with the gun and implements	2,264
Limber, packed	1,990
Caisson, packed	2,740
Gun with limber	4,255
Caisson, complete	4,731

England.—The cheeks are made each of a frame of angle-iron of the required form, re-enforced by welding to it at the place where the trunnion-bed should come a solid piece of iron of a thickness equal to the width of the angle-irons, and large enough to cut out of it the semicircular recess for the trunnion-bed, which is accomplished by means of a common band-saw. To the inner side of this frame a plate of boiler-iron of corresponding form is riveted. The cheeks are joined by two iron-plate transoms, one in front and the other in rear of the axle-body, by two bolts passing through iron pipes, and by the lunette. The cap-squares are secured by a chin-bolt which does not pass entirely through the cap-squares, and a pin which runs through the cheek and a hole in a lug welded to the under side of the cap-squares.

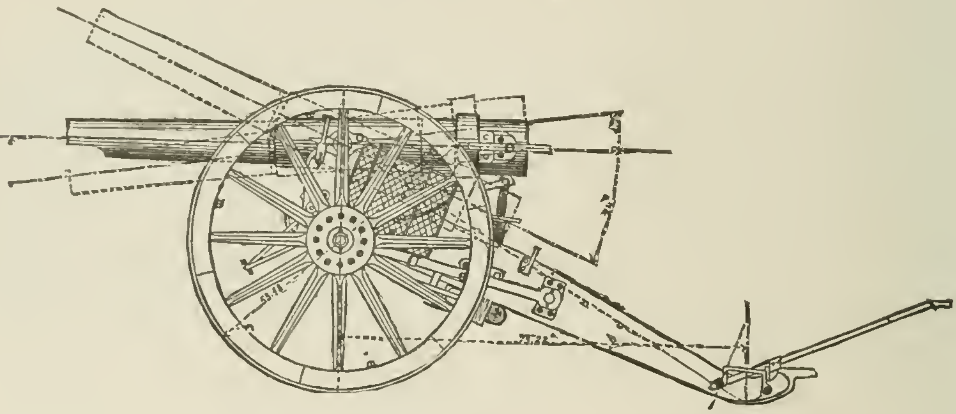

Fig. 4.

The elevating-apparatus (Fig. 5), which is known as the Whitworth pattern, consists of a long screw and bronze female screw with a bevel-gear cut on its lower surface. A spindle with a bevel-wheel on one end passes through the right cheek-piece, and has attached to it a bronze hand-wheel by which the screw is worked. The female screw and bevel-wheel are contained in a wrought iron box having trunnions which support it between the sides of the trail; the journal-boxes are bolted on the inside of the trail-pieces. The elevating-screw admits of elevations of 21° and depressions of 4°. The 16-pounder gun-carriage has a trail-box of sheet-iron, divided into two compartments, for holding the small tools. Its cover is fastened by a hasp and turn-buckle. The axle and axle-body are of iron, and constitute a beam, in section a box-girder. The body is riveted to the axle, and also to the cheeks, by means of angle-irons.

Two wooden boxes, strengthened by corner-irons and provided with iron handles, are secured to the axle-body, one on each side of the gun, and carry each two rounds of canister. They also serve as seats for two gunners. A step for their feet is fastened to the box, and when not in use slides out of the way. A lock-shoe is used to check the motion of the carriage down hill, and the chain is arranged so as to allow the wheel, when it is desired to unlock it, to run over the shoe, which is then picked up and hung on the carriage.

The wheels have bronze naves, which are in three pieces, the pipe-box being of harder metal than the two flanges. The felloes, of ash, and the spokes, of oak, are made by machinery. The inner ends of the spokes are wedge-shaped, and form when driven a perfect arch around the pipe-box. The tenons are not of the same diameter throughout their length, but are larger at the shoulder, and fit into the felloes bored with two bits of different sizes.

The limber is formed of three futchells, an angle-stay, a splinter-bar, and two stays, an axle, axle-body, and pintle hooks, all of iron, with foot-boards and shafts of wood. To diminish the weight thrown on the shaft-horse, the ammunition-chests are thrown well to the rear, and held by four knees of T-iron screwed to the rear side of the axle-bed. The limber is fitted for single, double, and treble draught, and for oxen. Three chests are carried on the limber. Two of them are similar. They are all made of wood, strengthened by corner-pieces of iron. The side chests are partitioned off to carry 18 rounds of ammunition. The center chest has copper partitions, and carries fuses, friction-primers, etc.

The caisson is of iron, with the exception of the foot-boards. The stock is formed of two channel-beams. The spare wheel is carried on an arm secured to two plates riveted to the inner sides of the beams forming the stock, the plates being bolted together with bolts having pipes over them between the plates. A block of elm to act as a stay is riveted to the stock. The caisson-body carries four ammunition-chests and four under-boxes. The ammunition-chests are the same as the side chests on the limber, except in some of the leather fittings. A lock-shoe is used, the same as for the gun.

The principal weights are as follows:

	9-pounder.	16-pounder.
Weight of gun-carriage, empty.........	1,300 lbs.	1,480 lbs.
Weight of gun-carriage, packed	2,320 lbs.	2,957 lbs.
Weight on pintle-hook, without gunners.	140 lbs.	147 lbs.
Weight of limber, empty..................	1,235 lbs.	1,270 lbs.
Weight of limber, packed................	1,731 lbs.	1,792 lbs.
Weight of caisson, empty................	2,725 lbs.	—— lbs.
Weight of caisson, packed..............	4,530 lbs.	4,660 lbs.

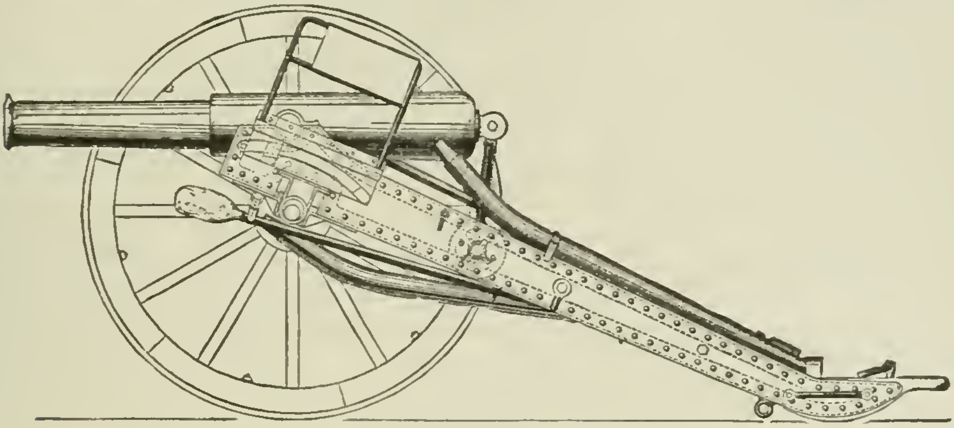

FIG. 5.

Germany.—The field-carriages are provided mainly by contract. Krupp makes the largest number. In his last model (Fig. 6) the cheek and trail-piece, instead of being strengthened by angle-iron riveted around the outer edge, is made of steel, and has this flange set up in a die while the metal is hot. The plates are first rolled to about the size required, then cut to the exact shape, heated to redness, and forced by means of hydraulic power into the die or former, which gives them the required form; that is, about 1½ inch of the edge of the plate all around is turned up like an angle-iron. This necessitates the provision of an expensive former, but when it has been once prepared the expense of making the cheek pieces is much diminished, while their weight for a given strength is considerably less than when the flange is riveted on. The cheeks are united by two plate transoms; that near the head of the cheeks is cut out so as to allow the gun to be depressed. The trail is further strengthened by the two ends of the trail-chest and the cover, which extends from the elevating-screw to the lunette, and by the different assembling-bolts. Each cheek is re-enforced by a system of braces secured to the inner faces between the flanges, and intended to prevent the trail from bending in firing.

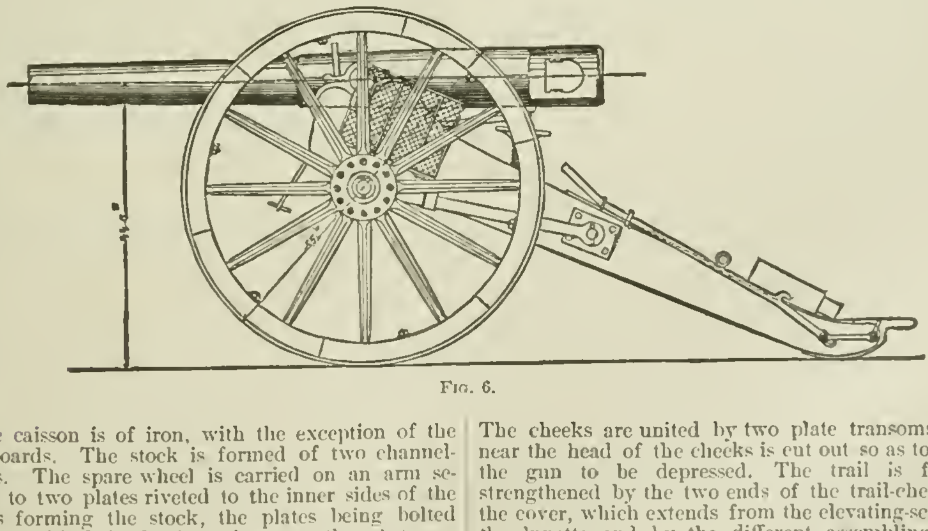

FIG. 6.

The axle is of tempered steel, and is cylindrical in the body. The arms are conical, and for a distance are flattened to hold the grease. The linch-pin is elliptical, and has a flat head, which may be used as a step. The wheels have bronze naves, twelve spokes and six felloes, of wood; their diameter is 55 inches (4 inches less than the model of 1864). The linch-washer is covered by a molding of the nave. Leather shoulder-washers are used to lessen the noise in marching. Two iron connecting-rods join the axles near the shoulder with the trail, strengthening the former. In the 9-centimeter these rods carry two seats for two gunners. The seats are provided with a back of netting, India-rubber springs to lessen the force of the shock going over rough roads, and a step for the convenience of the gunners taking their seats and to rest their feet on during the march. The carriage is provided with brakes, which are operated during the march by the gunners mounted on the axle-seats. The figure shows how these brakes are arranged; they may be also used to check the recoil in firing.

The elevating apparatus is composed of a double screw, the inner one having a flat head with a hole drilled in it. The breech rests on a bronze block, which is embraced by the two rod-supports; they turn around a horizontal bolt passing through the cheeks near the head of the carriage. The head of the inner screw is hinged to the rods under the block. The outer screw has a wheel-handle for giving the elevation. A small chain attached to the trail chest cover is used to place this wheel in its position, and

faces the gunner who is distributing the ammunition) has two rectangular openings, each provided with a door, which opens by turning down toward the rear. The doors are closed by means of hasps turning around the edge of the cover. An iron arc with two support-notches is attached to the right end of the cover and serves to hold it open.

Experimental caissons made of iron are now being tested with a view to their adoption.

The principal weights, in pounds, are as follows:

	3.1-in.	3.164-in.
Weight of the carriage with trail-handspike	1,080	1,157
Weight of the carriage with gun and implements	1,967	2,164
Weight of the trail on the ground..............	165	163
Weight of the limber not loaded	1,153	1,157
Weight of the ammunition	562	648
Weight of the tools, implements, etc............	253	253
Weight of the gun and carriage and limber without gunners	3,968	4,277
Weight for each horse without gunners..........	660	712
Weight of the caisson loaded for the batteries..	4,696	4,940

Russia.—This carriage is in its general construction like those already described. The cheeks are made of boiler-plate, .25 inch thick, and strengthened by angle-irons riveted around the edge. The axle is square in cross-section, 3 inches, and is strengthened to resist the recoil of the gun by a flat bar of iron bolted to it, the bolts not passing through the axle, but around it, and secured by nuts.

The wheels have bronze naves. Each felloe is bolted to the tire by a bolt near each end. Under the heads of each pair of bolts nearest each other is an iron plate, let into the under side of the felloe, and

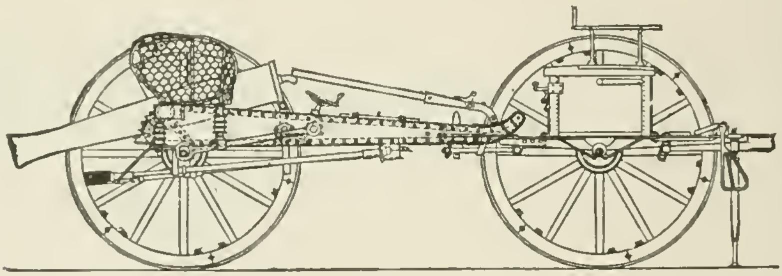

FIG. 7.

prevent it from turning during the march. The nut of the elevating-screw has trunnions which turn in trunnion-holes in the cheeks. The 8-centimeter gun-carriage will admit of elevations from 15° depression to 18° of elevation, and the 9-centimeter carriage from 15° depression to 16° of elevation.

Among the other irons of the carriage may be mentioned the trunnion-beds and cap-squares. These last are held in place by a vertical bolt, which passes through the flange, and serves as a handle for the man seated on the axle. The iron pointing-bar on the left cheek is movable around one of the lunette-bolts; it can be turned down to the rear, and rests on an iron fork on the cheeks. A case for grapeshot, with leather and felt lining, is on the left cheek, and on the right a sponge-ring near the axle-seat, and a sponge-socket near the lunette. A short rammer is transported in the trail-chest. It is composed of a wooden head and a hollow iron staff. It is used in placing the projectile and cartridge in position; the staff has a mark on it for this purpose. The staff may be also used to open the breech when it sticks; it is engaged in the handle as a key.

The wheels and axles of the limber are the same as for the carriage. Two parallel hounds embrace the pole at their front end, and are joined at the rear by a transom, to which the pintle-hook is fastened. The latest pattern is made of iron, with the exception of the wheels and pole.

The ammunition-chest is of sheet-iron, and has on it two iron supports for a leather back-strap for the gunners. The rear side (that is to say, that which

serving as a washer to the bolt-heads, thus strengthening the wheel at the junction of the felloes.

The elevating-screw is a double one, and allows of an elevation of 20°. The carriages made ten years ago were constructed with a top-carriage, which had a lateral motion around a vertical pintle fastened to the axle of the carriage. By this means the gunner could point the gun without depending upon the man at the trail-handspike to give it the exact direction. Experience showed, however, that the complication of the parts and the weakening of the carriage were not compensated for by the advantages gained, and this feature has been suppressed in the carriages of recent construction. The trail-handspike is of wood, shod with iron, and made fast to a hinge on the trail of the carriage, so that it can be, when not in use, folded back on the trail.

The ammunition-cart is covered with sheet-iron, and lined on the inside with coarse tow-cloth, glued to the wood. More recently the cart has been superseded by the caisson with four wheels, drawn by horses attached for draught as in our service.

Among the regular stores assigned to each battery is a brass mold for casting new jackets on projectiles which have been fired and recovered. The Khivan campaign developed serious objections to the leaden coat, some of the pieces having been rendered temporarily unserviceable by the leading of the bore. To prevent this in future, the lead-coated projectiles are covered with a composition made of 25 parts of beef-tallow, 50 parts of common soap, and 25 parts of paraffine, applied with a brush. New projectiles are provided with copper bands for filling the grooves and imparting rotation.

Instead of woolen sponges for sponging the bore, brushes are used; the bristles are held in place by pitch. Brass-wire brushes have been tried, but their use has been abandoned

The principal weights are as follows:

Gun, carriage, and limber, loaded, pioneers' tools and men's knapsacks included:	4,332 pounds for the 9-pounder. 3,660 pounds for the 4-pounder. 3,430 pounds for horse-artillery.
Weight for each horse, including five cannoneers, mounted on the carriage and limber:	720 pounds for the 9-pounder. 600 pounds for the 4-pounder. 550 pounds for horse-artillery.

France.—The French field-carriages resemble much the latest pattern of Krupp's carriage, in which the cheek-piece and flange are one piece.

Sweden.—The Swedish carriage (Fig. 7) is made of boiler-plate a little less than ¼ inch thick, strengthened by angle-iron, both on the top and bottom edges, the angle-iron being turned inward.

The elevating-screw is operated by means of a second screw, which turns the female screw of the former, thus raising or lowering the elevating-screw.

The limber has the pintle some distance in rear of the axle, thus serving to balance the pole and relieve the weight from the horses' necks.

The hounds are made of two pieces of angle-iron riveted together. See *Englehardt Gun-carriage.*

of the assailant should be swept not only by the front but the cross-fire of the assailed. 5. It should offer no obstructions to the free movements of the assailed either for the offensive or defensive, and afford facilities for active offensive movements at the opportune moment. 6. It should have secure natural points of support both on its flanks and in the rear. 7. It should afford every convenience for encamping and supplying the army. 8. Its lines of retreat should be ample and secure. As natural defensive positions, offering all or even the most essential of these advantages, are seldom met with, their defects have to be remedied by artificial means. These means from their object have received the name of *fortification*, which may therefore be defined as *the art of so arranging a position selected for defense that an inferior force shall be able to resist with advantage the assaults of one superior to it.* If the artificial means are of a durable character, and the position is to be permanently occupied, the works receive the name of *permanent fortification;* but when the position is to be occupied only for a short period, or during the operations of a campaign, perishable materials, as earth and wood, are mostly used, and the works are denominated *temporary* or *field-fortification.*

Fortifications should be regarded only as an accessory defensive means, but still a very important one, and they will conduce to the end proposed the more

FIELD-COLORS.—Small flags, about 1½ foot square, carried along with troops for marking out the ground for the squadrons and battalions; camp-colors.

FIELD-DAY.—A term employed when a regiment is taken out to the field for the purpose of being instructed in the field-exercise and evolutions.

FIELDED.—A term formerly used to imply *in the field of battle*, or *encamped.* The word is now obsolete.

FIELD-FORTIFICATION.—When an armed force is constrained to act on the defensive, either from inferiority in numerical strength or discipline to its adversary, it should endeavor to counterbalance this disparity against it by selecting a position on which to receive battle, which will afford every military advantage to itself, and prove, in a corresponding degree, unfavorable to the assailant. A defensive position to afford these advantages should satisfy the following conditions: 1. It should present natural obstructions to the advance of the assailed, so as to deprive him of the advantage which his superiority in numbers or discipline would give him in a hand-to-hand conflict. 2. The features of the ground should screen the assailed from the assailant's view, and offer covers from the assailant's fire, whilst their own fire can be used with full effect. 3. It should command or overlook the ground over which the assailant will be obliged to advance, in such a manner that its surface will be swept by the fire of the assailed. 4. In like manner all the lines of approach

nearly they are made to satisfy the foregoing conditions of a strong defensive position. To satisfy the first three of these conditions—viz., to offer an obstruction to a hand-to-hand conflict; to shelter the assailed from the view and fire of the assailant; and to afford the assailed a commanding view and a sweeping fire over the assailant's lines of approach, fortifications must consist of a covering mass of earth, stone, wood, or iron of sufficient height and thickness to screen the men behind it from view, and to intercept the missiles of the assailed, and of some obstruction in advance of it which will prove a serious obstacle in the way of the assailant's advance.

The covering mass is termed a *parapet* when it fulfills the last two of these conditions; when intended simply as a screen, as in the case of a cover for cavalry when waiting to be brought into action, it is termed an *epaulement;* and when used to cover troops from an enfilading fire on the flank or in the rear, a *traverse.*

The most usual obstruction to impede the enemy's advance to attack with the bayonet is a *ditch* placed in front of the parapet. When the parapet is of earth, the ditch furnishes the material for its construction. The drawing shows the form and relative dimensions of the profile of the parapet and ditch of an ordinary field-fortification. When the top surface of the platform, termed the *banquette tread* is too high to be reached from the ground by an ordinary step, a ramp, either of earth or timber, is placed in the rear of it, by which it is reached. This ramp is called the *banquette slope*. The interior face of the parapet, when arranged for musketry, is termed the *breast-height* or *interior slope*; when for artillery, the *genouillère*. The top of the parapet is the *superior slope*. The exterior face is termed the *exterior slope*. Between the parapet and ditch a narrow zone is usually left on the natural surface of the ground, which is termed the *berm*. The side of the ditch adjacent to the parapet is termed the *scarp*; the side opposite to this, the *counterscarp*. A mound of earth placed in front of the counterscarp, with a gentle slope outwards, is termed the *glacis*. To obtain speedy cover, the parapet is formed from a ditch within, termed a *trench*, of sufficient depth, with the height of the parapet, to give shelter to the troops when standing in the trench. The natural ground serves as the banquette tread in this case.

The measures taken for the attack and defense of fortifications have an interdependence so intimate that the dispositions made by the one party naturally control those that the other may make. The assailing force naturally seeks to advance on those points which offer the least obstruction, either by their passive strength or by the fire which sweeps the ground over which the advance has to be made. The most favorable case for the assailant will be where no fire from the assailed sweeps over the ground along which he advances; the next is where, although the missiles of the assailed sweep above the approach, they pass so high above the assailant as to inflict no injury. See *Field-intrenchments, Field-works, Flanked Disposition, Fortification, Inclosed Works, Line of Works, Profiling*, and *Tracing*.

FIELD-GLASS.—The double or binocular telescope, constructed optically on the principle invented by Galileo, and designed to give clear and distinct views of natural scenery by sea or land. Each tube of the glass contains a convex or magnifying achromatic object lens and a concave or negative eye-lens, which are placed at nearly the distance of their focal length apart. Thus, if the object-lens is of five inches focus and the eye-lens of one inch negative focus, the length of the bodies will be about four inches and the power will be about five times. To obtain a greater magnifying power with glasses constructed on the Galilean principle, the distance between the object- and eye-lenses must be increased until the limit of convenient portability is reached, which is found to be about eight times. If it be desired to apply the principle of binocularity to higher powers, an ordinary refracting telescope must be employed. The field- or marine-glass being intended for all out-door use, and being necessarily employed in hazy weather or after nightfall, is constructed with large object-lenses for the light-gathering, and with shades to extend beyond both the object-glasses, to shield the latter from sun or rain.

Gem Field-glass.

Their frames are made very substantially, to endure the rough handling to which they may be subjected, and they are carried in strong sole-leather cases, with straps for slinging over the shoulders. But they are bulky and heavy, rendering it very desirable that a glass combining their good qualities with greater portability and lightness should be procurable for many purposes. These desiderata are fully realized in the Gem, a glass manufactured by Walmsley & Co., and largely issued by the United States Government to officers serving on the Plains.

FIELD-GUN.—A small kind of gun or cannon used on the battle-field. Often called a field-piece. See *Field-artillery*.

FIELD-HOSPITAL.—The Staff and apparatus for the surgical treatment of the wounded in the field, and the locality assigned for the resort of the latter to obtain it. In the United States there is a hospital at every military post, under the superintendence of the Medical Department. In the French army the service of the field-hospitals forms part of the intendance of the army, the Medical Officers in charge being under the supreme control of the Intendant General. See *Hospitals*.

FIELD-INTRENCHMENTS.—When positions are to be taken up and lines of intrenchments or detached works are to be constructed, it is the duty of artillery officers, in co-operation with those of engineers, to select positions for batteries and determine the kind and amount of armament therefor. It is therefore necessary that they should be thoroughly conversant with the principles of military engineering, and especially those of field-intrenchments. The object of every fortification is to shelter the troops occupying it from the view and fire of an assailant, and at the same time to afford them a commanding view and sweeping fire over their enemy. Earth is the principal material employed on land for resisting the fire of artillery. Wood, iron, and masonry are used in conjunction with it, principally for sustaining purposes. As a material for fortifications, earth possesses advantages over all other, being found ready at hand in almost all localities where wanted for such purposes, being easily handled, and possessing unrivaled properties of resistance as a covering mass against projectiles.

Field-intrenchments may be classified as follows: 1. Intrenched camps; 2. Intrenched lines of battle; 3. Detached works; 4. Lines of works; 5. Works auxiliary to permanent fortifications; 6. Works for siege-operations. So far as artillery is concerned, the first object to be considered is position, the general principles of which are the same for each of the above classes, and which may be briefly stated as follows: 1. Artillery should, if possible, overlook all the ground within range over which an enemy might advance, and the pieces be so placed as to sweep the entire surface with their fire, those of longest range occupying the most commanding positions. 2. All the lines of approach of the assailant should be swept not only by the frontal, but by the flank or cross fire of the assailed. 3. The features of the ground should screen the assailed from the assailant's view, and afford cover from his fire whilst that of the assailed can be delivered with full effect. 4. The position should, if possible, present natural obstructions to the advance of the assailant. 5. It should offer no obstructions to the free movements of the assailed, either for the offensive or defensive, and should afford facilities for active offensive movements at the opportune moment. 6. It should have secure supports, both on its flanks and in the rear. 7. It should afford every convenience for encamping and being supplied. See *Field-fortification, Intrenched Camps*, and *Intrenchment*.

FIELD MARSHAL.—The highest rank of General Officers in the British and other foreign armies. In the former it is a special honor enjoyed by very few officers, and only conferred by selection, either on the ground of distinguished service or of royal birth. When unemployed, the Field Marshal has no higher pay than any other General, but if commanding an army he receives £16 8*s*. 9*d*. a day for staff-pay, while a General has but £9 9*s*. 6*d*. The equivalent rank in the Navy is that of Admiral of the Fleet. Formerly a Captain General was occasionally appointed, who had rank higher even than a Field Marshal.

FIELD OFFICER.—An officer above the rank of Captain and below that of General. Thus a Major, Lieutenant Colonel, or Colonel, whether of brevet or regimental rank, is a Field Officer. A Field Officer in the English army in command of his regiment retains the command for five years, but can be reappointed at the will of the Commander-in-Chief.

FIELD OFFICER'S COURT.—In the United States service, a Court-Martial consisting of one Field Officer empowered to try all cases, subject to jurisdiction of Garrison and Regimental Courts. It takes the place of the latter Courts in time of war, but cannot be held in time of peace. See *Courts-Martial*.

FIELD OF THE CLOTH OF GOLD.—A plain near Guisnes, in the Department of Calais, France, where Henry VIII. of England and Francis I. of France held a conference in June, 1520. The Throne of France was sought for by Charles I. of Spain (afterwards Charles V.), and Francis sought the friendship of the English King. To bring about such a result Francis proposed to raise Cardinal Wolsey to the Papacy. Wolsey brought about and conducted the meeting, which was attended with so much splendor of pageantry as to give the peculiar title to the place. The solemnities occupied nearly three weeks. Ten days were spent in the feats of arms for which Wolsey had provided. There were tilting with lances, and tourneys on horseback with the broadsword, and fighting on foot at the barriers. The Kings were always victorious against all comers. On Midsummer Day the gaudy shows were over.

FIELD-PARK.—The spare carriages, reserved supplies of ammunition, tools, and materials for extensive repairs and for making up ammunition, for the service of an army in the field, form the field-park, to which should be attached also the batteries of reserve. See *Park*.

FIELD-REMEDIES.— Peculiar and local diseases prevail in nearly every section of country; and wounds from gun-shot and weapons, bruised and broken bones, are casualties that may befall soldiers in the field at any time. It is, therefore, important for all to have, in cases of emergency, a sufficient knowledge of medicine and practical surgery to enable them to relieve the sick and wounded until professional aid can be secured. It is not necessary to provide a very extensive collection of medicines, etc. The list detailed for the *medicine-chest* will be found sufficient. Many natural remedies present themselves in all localities, and very simple modes of treatment, if understood, will relieve much suffering. The following remedies and modes of procedure should be carefully noted, as it is quite impossible to experience even a brief service in the field, without the necessity of resorting to some of them:

Scurvy may be prevented by employing the following antiscorbutics: 1. Any fresh vegetables, wild onions, fresh fruit, and even unripe fruit, with a risk of diarrhea. 2. Dried or canned vegetables, especially potatoes and cauliflower. 3. Vinegar, citric acid or lemon-juice. 4. Citrates, malates, tartrates and lactates of potash, used in food or drink. 5. Pure air, exercise, and cleanliness. 6. Tincture of chloride of iron, taken daily, or infusion of hemlock-leaves. 7. Raw potatoes and fresh raw meat. *Malaria* should be promptly checked. Quinine in sufficient doses is the remedy. A halt to the leeward of a marsh or swamp should be avoided. A camp on low ground is often less affected by malaria than the low hills that overlook it. Violent exertion, resulting in exhaustion and perspiration, often averts an attack, and any simple aperient is likewise good. *Diarrhea* may be treated with an ounce of castor-oil and fifteen drops of laudanum suspended in water. The patient should eat neither bread nor meat, but confine his diet to a little rice-broth, thickened milk, and the like. If it is accompanied by severe cramps, apply hot rocks or pans to the feet and hot fomentations to the stomach. *Poisoned* persons must be treated with the greatest caution, inasmuch as it is necessary to deal with dangerous remedies. Some poisons are best ejected by vomiting, and an emetic should be promptly given; in others, the action on the stomach may be diminished by oily and mucilaginous drinks, such as magnesia, milk and oil, barley-water, flour and water, and raw eggs. For poisonous acids, such as nitric, oxalic, muriatic, or sulphuric acid, avoid emetics. For nitrate of silver, give plenty of salt water, followed by barley-water or gruel. For strychnine, narcotic poisons, opium, mushrooms, belladonna, etc., give strong emetics at once, pour cold water on the head, neck, and shoulders, place mustard-poultices on the feet, and keep the person moving about, giving strong coffee as a stimulant. Water should always accompany the emetic, to make the vomiting easy, and great effort made to prevent the patient from becoming drowsy and stupid. A charge of gunpowder swallowed in water, mustard in hot water, or warm soapsuds are prompt emetics. In the absence of all these, a careful tickling of the throat often does the work. The following are good poultices: *Mustard-poultice*—two ounces powdered mustard, two ounces linseed-meal, eight ounces boiling water; *Charcoal-poultice*—one third ounce charcoal, two ounces bread, one ounce linseed-meal, eight ounces boiling water. For *suffocation by gases, etc.*, remove the patient to pure air, apply cold water to the face and chest, rub the body briskly, give hot coffee or spirits, and endeavor to induce artificial respiration.

For *sore and blistered feet*, undiluted whiskey and melted tallow rubbed on the foot, which is afterwards covered with a sock, act well. Great relief is found in tepid bathing, a small quantity of alum or salt being dissolved in the water. The feet should be washed daily, while on the march, and both the feet and inside of the stockings should be well soaped. In severe cases of soreness, a raw egg broken in the boot before putting it on is a splendid antidote. Blisters of the feet should not be opened, but a thread should be drawn through them and the liquid allowed to run off. If the foot-soreness is simply owing to bad boots or socks, relief may be often found by changing the boots and socks from one foot to the other, and turning the stockings inside out. *Chafing* is remedied by keeping the parts clean and powdering with fuller's earth. Sprains are relieved by hot fomentations and by rags kept saturated with cold water and bound round the parts. *Burns and scalds* are treated by keeping them from exposure to the air and applying carron-oil (a mixture of equal parts of oil and lime-water), flour, or scraped potatoes. *Snow-blindness* is an affection to be met with in all localities where there are glaring sheets of snow. Some persons are simply blind, others experience great pain, the lips chapping, and the face and exposed parts severely blistering. A person having once experienced snow-blindness is subject to frequent attacks. Green or blue glasses and a green-lined broad-brimmed hat give to the eyes protection. In the absence of glasses, wet powder and grease, or charcoal, smeared on the nose and about the eyes, will afford much relief. A few drops of opium, in tincture, placed within the eyelids will also afford relief. Water and weak brandy is an excellent eye-wash. For *sunstroke*, remove the collar and stock, loosen the shirt and coat, and continue to throw cold water on the head and spine until consciousness returns. For *wasp and scorpion stings, etc.*, extract the sting, if it remains in the wound, and rub acetic acid, the nicotine from a pipe, or chewed tobacco, upon the wound.

Rattlesnakes and venomous reptiles are met with in most localities, and their bites are of frequent occurrence. As an antidote the Western mountaineers of America place great dependence on strong whiskey. The action of the poison seems to counteract the effects of the whiskey, and a very large quantity may be taken without causing intoxication. No time should be lost in administering the spirits. Hartshorn applied externally and taken internally, in small doses, is a good remedy. Plaintain-leaves finely chewed and applied to the wound, after sucking out the poison, are also good. Pulverized indigo made into a soft poultice will draw out the poison when applied to the wound. The poison turns the indigo white. When the indigo ceases to change color it is a sign that the poison has been withdrawn. In the absence of antidotes, tie a ligature as firmly as possible above the wounded part, suck the wound, if the mouth and lips be free from sores, and caustic it. If no caustic be at hand, explode gunpowder into the wound, or burn it out with the end of a bayonet or ramrod heated to a white heat, avoiding the arteries. Use every effort to prevent the patient from falling into the lethargy and drowsiness that always follow. The following cruel course is often taken by the Indians of the Northwest in treating a poisonous bite: A bird or animal with a quick circulation of the blood is secured, an incision is made into the flesh of the creature and placed in contact with the wound. The bird or animal soon dies. This is repeated several times until the contact produces no effect, when the victim is considered out of all danger. A bandage is generally placed between the wound and the heart to prevent the return of venous blood.

The following is the proper treatment of the apparently dead from intense cold: Rub the body with snow, ice, or cold water. Restore warmth gradually; and after some time, if necessary, employ the means recommended for the drowned. In these accidents it is very dangerous to apply heat too early. In order to restore the natural warmth of the body, move a heated warming-pan over the back and spine, and rub the body briskly with the hands. To restore breathing, place the pipe of a common bellows (when procurable) into one nostril, carefully closing the other and the mouth; at the same time push gently downwards and backwards the upper part of the windpipe, so as to allow a freer admission of air; blow the bellows gently to inflate the lungs, until the breast be slightly raised; the mouth and nostrils should then be set free, and a moderate pressure with the hand brought to bear upon the chest. Repeat this process until life appears. Any of the following may be useful helps: 1. The application of sal-volatile or hartshorn to the nostrils. 2. The early employment of electricity by a skillful person. 3. The injection of half a pint of warm brandy and water, or wine and water, into the stomach. See *Medicine-chest*, *Military Surgery*, *Swimming*, and *Wounds*.

FIELD-SERVICE.—In the United States, the formation by divisions is the basis of the organization and administration of armies in the field. A division consists usually of two or three brigades, either of infantry or cavalry, and troops of other corps in the necessary proportion. A brigade is formed of two or more regiments. As the troops arrive at the rendezvous, the General Commanding-in-Chief organizes them into brigades and divisions. Brigades in divisions and divisions in corps receive permanent numerical designations, as first, second, and third. In a single army, corps are designated in like manner. If there be more than one army, corps are numbered consecutively from the first to the last one organized. In reports of military operations, brigades and divisions are designated by the name of the General commanding them. The General Commanding-in-Chief assigns the Generals of divisions and of brigades to their respective commands, when the assignment is not made by the Department of War. The General of Brigade inspects his troops in detail, by companies, when he takes the command and at the opening of the campaign, and as often as may be necessary to ascertain exactly their condition. The General of Division makes similar inspections when he thinks proper. At these inspections the Generals examine the arms, clothing, equipments, harness, horses, etc., direct the necessary repairs, and designate the men and horses to remain in depot or march with the train. Staff Officers, and Officers of Engineers, Ordnance, and Artillery, according to the nature of the service, are assigned to the headquarters of armies and divisions, and detached brigades, by order of the General Commanding-in-Chief, when the distribution of these officers has not been regulated by the War Department. The necessary Staff is also assigned to Commanders of Brigades. The report of the Officer of Engineers embraces plans of military works executed during the campaign, and, in case of siege, a journal of the attack or defense.

At the opening of a campaign, the Commander of an army determines and announces in orders the number of orderlies, mounted or foot, for the Generals. Orderlies for Corps, Division, and Brigade Commanders of Infantry are detailed from the Infantry, and are mounted; for Artillery and Cavalry Commanders, from their commands. In marches, the mounted orderlies follow the Generals, and perform the duty of escorts, or march with orderlies on foot at the head of the division or brigade. The Staff Officer who distributes the orderlies to their posts sends with them a note of the time and place of departure; those relieved receive a like note from the Staff Officer at the headquarters.

In active campaign, troops should be prepared to bivouac on the march, the allowance of tents being limited, about as follows: For the headquarters of an army corps, division, or brigade, one wall-tent to the Commanding General, and one to every two officers of his Staff. For the Colonel, Field, and Staff of a full regiment, three wall-tents; and for every other commissioned officer, one shelter-tent each. For every two non-commissioned officers, soldiers, officers' servants, and authorized camp-followers, one shelter-tent. One hospital-tent is allowed for office purposes at corps headquarters, and one wall-tent at those of a division or a brigade. Hospital-tents are for the sick and wounded, and, except those allowed for army corps headquarters, should not be diverted from their proper use. Officers' baggage is limited to blankets, one small valise or carpet-bag, and a moderate mess-kit. The men carry their own blankets and shelter-tents, and reduce the contents of their knapsacks as much as possible.

Reconnoissances should precede the establishment of a camp. For a camp of troops on the march, it is only necessary to look to the health and comfort of the troops, the facility of the communications, the convenience of wood and water, and the resources in provisions and forage. For an intrenched camp, or a camp to cover a country, or one designed to deceive the enemy as to the strength of the army, the ground must be selected, and the camp arranged for the object in view. The camping-party of a regiment consists of the Regimental Quartermaster and Quartermaster Sergeant, and a Corporal and two men per company. The General decides whether the regiments camp separately or together, and whether the police guard shall accompany the camping-party, or a larger escort shall be sent. The watering-places are examined, and signals placed at those that are dangerous. Any work required to make them of easier access is done by the police guard or Quartermaster's men. Sentinels, to be relieved by the guards of the regiment when they come up, are placed by the camping-party over the water if it is scarce, and over the houses and stores of provisions and forage in the vicinity. If the camping-party does not precede the regiment, the Quartermaster attends to these things as soon as the regiment reaches the camp. On reaching the ground, the infantry form on the color front, the cavalry in rear of its camp. The number of men to be furnished for guards, pickets, and orderlies; the fatigue-parties to be sent for supplies; the work to be done, and the strength of the working parties; the time and place for issues; the hour of marching, etc., are then announced by the Brigadier Generals to the Colonels, and by them to the Field Officers. The artillery is parked near the troops to which it is attached, so as to be protected from attack, and to contribute to the defense of the camp. Sentinels for the park are furnished by the artillery, and, when necessary, by the other troops. In the cavalry, each troop moves a little in rear of the point at which its horses are to be secured, and forms in one rank; the men then dismount; a detail is made to hold the horses; the rest stack their arms and fix the picket-rope; after the horses are attended to, the tents are pitched, and each horseman places his carbine at the side from the weather, and hangs his saber and bridle on it. The standard is then carried to the tent of the Colonel. The front of the camp is usually equal to the front of the troops. The tents are arranged in ranks and files. The number of ranks varies with the strength of the companies and the size of the tents. The Staff Officer charged with establishing the camp designates the place for the shambles.

When bivouacking, the distance from the enemy decides the manner in which the horses are to be fed and led to water. When it is permitted to unsaddle, the saddles are placed in the rear of the horses. For infantry, the fires are made in rear of the *color-line*, on the ground that would be occupied by the tents in camp. The companies are placed around them, and, if possible, shelters are made. When liable to surprise, the infantry should stand to arms at daybreak, and the cavalry mount until the return of the reconnoitering parties. If the arms are to be taken apart to clean, it must be done by detachments, successively.

When in cantonment, the Regimental Commander indicates the place where the command shall assemble in case of alarm. It should generally be outside the cantonment; the egress from it should be free; the retreat upon the other positions secure, and roads leading to it on the side of the enemy obstructed. Near the enemy, companies or platoons should be collected, as much as possible, in the same houses. If companies must be separated, they should be divided by platoons or squads. When cavalry and infantry canton together, the latter should furnish the guards by night, and the former by day. Troops cantoned in presence of the enemy should be covered by advanced guards and by natural or artificial obstacles. Cantonments taken during a cessation of hostilities should be established in rear of a line of defense, and in front of the point on which the troops would concentrate to receive an attack. The General Commanding-in-Chief assigns the limits of their cantonments to the divisions, the Commanders of Divisions to brigades, and the Commanders of Brigades post their regiments. The position for each corps in case of attack is carefully indicated by its Commanding Officer.

The General who establishes an intrenched post gives to its Commander detailed instructions in regard to its defense, and to the circumstances under which the defense should cease. The Commander reconnoiters his post; distributes the troops; posts the officers and non-commissioned officers; forms a reserve; gives orders for all contingencies he can foresee, and arranges his troops so as to prepare them for attack, day or night.

The grand depots of an army are established where the military operations would not expose them to be broken up. Smaller depots are organized for the divisions and for the several arms. They are commanded by officers temporarily disabled for field-service or by other officers if necessary, and comprise, as much as possible, the hospitals and depots for convalescents. When conveniently placed, they serve as points for the halting and assembling of detachments. They receive the disabled from the corps on the march; and the officers in command of the depots send with the detachments to the army those at the depots who have become fit for service. In the field verbal orders and important sealed orders are carried by officers, and, if possible, by Staff Officers. When orders are in writing, the place and time of departure should be marked on them, and place and time of delivery on the receipt. Dispatches, particularly for distant corps, should be intrusted only to officers to whom their contents can be confided. In a country occupied by the enemy, the bearer of dispatches should be accompanied by at least two of the best mounted men; should avoid towns and villages, and the main roads; rest as little as possible, and only at out-of-the-way places. Where there is danger, he should send one of the men in advance, and be always ready to destroy his dispatches. He should be adroit in answering questions about the army, and not be intimidated by threats. The precise time when the dispatch is sent off, and the rate at which it is to be conveyed, should be written clearly on the covers of all letters transmitted by a mounted orderly, and the necessary instructions to him, and the rate of travel going and returning, should be distinctly explained to him. The parole and countersign are issued daily from the principal headquarters of the command. The countersign is given to the sentinels and non-commissioned officers of guards; the parole to the commissioned officers of guards. When the parole and countersign cannot be communicated daily to a post or detachment which ought to use the same as the main body, a series of words may be sent for some days in advance. If the countersign is lost or one of the guard deserts with it, the Commander on the spot substitutes another, and reports the case at once to the proper Superior, that immediate notice may be given to headquarters.

When the wants of the army absolutely require it, and in other cases, under special instructions from the War Department, the General Commanding the Army may levy contributions in money or kind on the enemy's country occupied by the troops. No other Commander can levy such contributions without written authority from the General Commanding-in-Chief.

While the general laws and necessity of war may, in certain cases, justify the seizure and conversion of private property for the subsistence, transportation, and other public uses of the army, yet the Rules and Articles of War denounce the severest penalties against pillage, and the taking or appropriation of property for private purposes, whether the offense be committed within the United States or in an enemy's country. All property, public or private, lawfully taken from the enemy, or from the inhabitants of an enemy's country, by the forces of the United States, instantly becomes the public property of the United States, and must be used and accounted for as such. It is forbidden to purchase horses without ascertaining the right of the party to sell. Estrays, in the enemy's country, when the owner is not discovered, are taken for the army. Officers are held strictly responsible that all property taken from alleged enemies by them, or with their authority, is inventoried and duly accounted for.

A police guard is detailed in each regiment daily, consisting of two Sergeants, three Corporals, two drummers, and men enough to furnish the required sentinels and patrols. An advanced-post is detached from the police guard, composed of a Sergeant, a Corporal, a drummer, and nine men to furnish sentinels and the guard over the prisoners. The men are the first of the guard roster from each company. The men of the advanced-post must not leave it under any pretext. Their meals are sent to the post. The advanced-post furnishes three sentinels—two a few paces in front of the post, opposite the right and left wing of the regiment, posted so as to see as far as possible to the front, and one over the arms. In the cavalry, dismounted men are employed in preference on the police guard. The mounted men on guard are sent in succession, a portion at a time, to groom their horses. The advanced-post is always formed of mounted men. The police guard and the advanced-post pay the same honors as other guards. They take arms when an armed body approaches.

Deserters from the enemy, after being examined, are secured for some days, as they may be spies in disguise; as opportunities offer they are sent to the rear; after which, if they are found lurking about the army, or attempting to return to the enemy, they are treated with severity. The arms and accouterments of deserters are turned over to the Ordnance Department, and their horses to the corps in want of them, after being branded. The enlistment of deserters from the enemy, without express permission from General Headquarters, is prohibited. Plundering and marauding, at all times disgraceful to soldiers, when committed on the persons or property of those whom it is the duty of the army to protect become crimes of such enormity as to admit of no remission of the awful punishment which the military law awards against offenses of this nature.

The picket is detailed daily after the details for duty of the first class, and from the next for detail on the roster of that class. It is designed to furnish detachments and guards unexpectedly called for in the twenty-four hours; it counts as a tour of the first class to those who have marched on detachment or guard, or who have passed the night in bivouac. The picket of a regiment is composed of a Lieutenant, two Sergeants, four Corporals, a drummer, and about forty privates. For a smaller force the picket is in proportion to the strength of the detachment. The picket is assembled by the Adjutant at guard-mounting; it is posted twelve paces in rear of the guard, and is inspected by its own Commander. When the guard has marched in review, the Commandant of the picket marches it to the left of the police guard, where it stacks its arms and is dismissed. The officers, non-commissioned officers, and soldiers of the picket are at all times dressed and equipped; the horses are saddled, and knapsacks and valises ready to be put on. The picket does not assemble at night except in cases of alarm, or when the whole or a part is to march; then the Officer of the Day calls the officers, who call the non-commissioned officers, and the latter call the men; for this purpose each ascertains the tents of those he is to call. They are assembled without beat of drum or other noise. At night, cavalry pickets assemble mounted.

The grand guards should cover the approaches to a camp or cantonment. Their number, strength, and position are regulated by the Commanders of Brigades; in detached corps, by the Commanding Officer. When possible, the grand guards of cavalry and infantry are combined, the cavalry furnishing the advanced sentinels. When the cavalry is weak, the grand guards are infantry, but accompanied by a few cavalry soldiers, to obtain and carry intelligence of the enemy. The strength of the grand guard of a brigade depends on its object and the strength of the regiments, the nature of the country, the position of the enemy, and the disposition of the inhabitants. It is usually commanded by a Captain. Grand guards usually mount at the same time as the other guards, but may mount before daybreak if the General of Brigade thinks it necessary to double the outposts at that time. In this case they assemble and march without noise, and during their march throw out scouts—a precaution which should always be taken in the first posting of a grand guard. The doubling of guards weakens the corps and fatigues the men, and should seldom be resorted to, never when preparing to march or fight. The Commander of a grand guard receives detailed instructions from the General and Field Officer of the Day of the brigade, and instructs the Commanders of the small posts as to their duties and the arrangements for defense or retreat. If the small posts are to change their positions at night, they wait until the grand guard is in position and darkness hides their movements from the enemy; then march silently and rapidly under the charge of an officer.

In war, every Commander of a fortified place always holds himself prepared with his plan of defense, as if at any time liable to attack. He arranges this plan according to the probable mode of attack; determines the posts of the troops in the several parts of the works, the reliefs, the reserves, and the details of service in all the corps. He draws up instructions for a case of attack, and exercises the garrison according to his plan of defense. In sea-coast works, he provides the instructions for the different batteries on the approach of ships. In framing his plan, he studies the works and the exterior within the radius of attack and investment, the strength of the garrison, the artillery, munitions of war, subsistence and supplies of all kinds, and takes immediate measures to procure whatever is deficient of troops or supplies, either by requisition on the Government or from the means put at his disposal. On the approach of an enemy, he removes all houses and other objects, within or without the place, that cover the approaches, or interrupt the fire of the guns or the movements of the troops. He assures himself personally that all posterns, outlets, embrasures, etc., are in proper state of security. He should be furnished, if possible, with a plan of the works, showing all the details of the fortifications and of the exterior within the radius of attack; with a map of the environs within the radius of investment; with a map of the vicinity, including the neighboring works, roads, water-channels, coasts, etc.; with a memoir explaining the situation and defense of the place, and the relations and bearings of the several works on each other, and on the approaches by land and water—all which he carefully preserves, and communicates only to the Council of Defense.

The Commander defends in succession the advanced-works, the covered-way and outworks, the body of the work, and the interior intrenchments. He is not content with clearing away the foot of the breaches, and defending them by abatis, mines, and all the means used in sieges, but he begins in good time, behind the bastions or front of attack, the necessary intrenchments to resist assaults on the main work. He uses his means of defense in such manner as always to have a reserve of fresh troops, chosen from his best soldiers, to resist assaults, retake the outworks, and especially to resist the assaults on the body of the place; and a reserve of provisions for the last period of the siege, and of ammunition for the last attacks. He endeavors in every case to compel the besieging force to approach by the slow and successive works of siege, and sustains at least one assault on a practicable breach in the body of the place. When the Commander thinks that the end of the defense has come, he consults a Council of Defense on the means that may remain to prolong the siege. But in all cases he alone decides on the time, manner, and terms of the surrender. In the capitulation he does not seek or accept better terms for himself than for the garrison, but shares their fate, and exerts his best endeavors for the care of the troops, and especially of the sick and wounded. Near an enemy, daily réconnoissances are made to observe the ground in front, and to discover whether the advanced-guards of the enemy have been increased or put in motion, or any other sign of his preparation for march or action. Reconnoitering parties should observe the following precautions: To leave small posts or sentinels at intervals, to transmit intelligence to the advanced-posts of the army, unless the return is to be by a different route; to march with caution, to avoid fighting; and see, if possible, without being seen; to maintain an advanced-guard; to send well-mounted men ahead of the advanced-guard, and on the flanks of the party; to instruct the scouts that no two should enter a defile or mount a hill together, but to go one at a time, while one watches to carry the news if the other is taken. Special reconnoissances are made under the direction of the General Officer in command, by such officers and with such forces as he may direct. Offensive or forced reconnoissances are to ascertain with certainty points in the enemy's position, or his strength. They are sometimes preludes to real actions, and sometimes only demonstrations. They drive back his outposts, and sometimes engage special corps of his line. They are only made by the order of the General Commander-in-Chief, or the Commander of an isolated corps.

The strength and composition of the escort of a convoy depend on the country, the nature and value of the convoy, and the dangers it may incur. A larger escort is required for a convoy of powder, that the defense may not be near the train. The advance-guard precedes the convoy far enough to remove all obstacles to its advance. It examines the woods, defiles, and villages, and by mounted men gives information to the Commander, and receives his orders. It reconnoiters places for halts and parks. When the rear is threatened, the rear-guard defends the ground and retards the enemy by breaking the bridges and blocking the road. If the flanks are threatened, and the ground is broken, and many defiles are to be passed, the defense of the convoy becomes more difficult; the advance and rear guards must be reduced, the flanks strengthened, and positions which will cover the march of the convoy must be occupied by the main body of the troops before the head of the convoy reaches them, and until it has passed. If the convoy is large, and has to pass places that the force and position of the enemy make dangerous, the loss of the whole convoy must not be risked; it must pass by divisions, which reunite after the passage. In this case the greater part of the troops guard the first division; they seize the important points, and cover them with light troops, or, if necessary, with small posts, and hold them until all the divisions have passed. On the appearance of the enemy during the march, the Commander closes up the wagons and continues his march in order; he avoids fighting; but if the enemy seizes a position that commands his road, he attacks vigorously with the mass of his force, but does not continue the pursuit far from the convoy. The convoy halts, and resumes the march when the position is carried. When the enemy is too strong to be attacked, the convoy is parked in square if there be room; if not, closed up in double file, at the front and rear the road is blocked by wagons across it. The drivers are dismounted at the heads of the horses. They are not permitted to make their escape. The light troops keep the enemy at a distance as long as possible, and are supported when necessary, but prudently, as the troops must be kept in hand to resist the main attack. When a whole convoy cannot be saved, the most valuable part may sometimes be by abandoning the rest. If all efforts fail, and there is no hope of succor, the convoy must be set on fire and the horses killed that cannot be saved; the escort may then cut its way through. If the convoy be of prisoners of war, every effort should be made to reach a village or strong building where they may be confined; if forced to fight in the field, the prisoners must be secured and made to lie down until the action is over.

The wagons or pack-animals allowed to a regiment, battery, or squadron should carry nothing but forage for the teams, cooking-utensils and rations for the troops, hospital stores, and baggage. One wagon, or an equivalent of pack-animals, to each regiment should transport exclusively hospital supplies, under the direction of the Regimental Surgeon; the one for regimental headquarters should carry the grain for the officers' horses; and the three allowed for each battery or squadron should be loaded with rations and forage in proper proportions for the same number of days' supply of each. Stores in bulk and ammunition should be carried in the regular or in special supply-trains. In large commands the roads, if possible, are left to the artillery and trains. The order of march should state whether the troops or trains have the right of way. The order for the movement of the divisions, brigades, and regiments contains the necessary directions in regard to the assembling and marching of the respective trains. The several trains march in an order analogous to the rank of the Generals, and the order of battle of the troops to which they belong. Trains are not allowed in any case to be in the midst of the troops, or to impede the march of the troops. General Officers should not permit any General or Staff Officer or regiment under their orders, or any person whatsoever attached to their command, to have more than the authorized amount or means of transportation. For this purpose they should themselves make, and cause to be made, frequent reviews and inspections of the trains. They should see that no trooper is employed to lead a private horse, no soldier to drive a private vehicle, and that no trooper is put on foot to lend his horse to an officer. They should not permit the wagons of the artillery or of the train to be loaded with anything foreign to their proper service, nor any public horse, for any occasion, to be harnessed to a private carriage. It is the duty of the Medical Director, or Chief Medical Officer, of the army corps, previous to a march, and previous to and in time of action, or whenever it may be necessary to use the ambulances, to issue the proper orders for the distribution and management of the same, for collecting the sick and wounded and conveying them to their destination. And it is the duty of his assistants faithfully and diligently to execute such orders.

If two corps meet on the same road, they pass to the right, and both continue their march, if the road is wide enough; if it is not, the first in the order of battle takes the road, the other halts. A corps in march must not be cut by another. If two corps meet at cross-roads, that which arrives last halts if the other is in motion. A corps in march passes a corps at a halt, if it has precedence in the order of battle, or if the halted corps is not ready to move at once. A column that halts to let another column pass resumes the march in advance of the train of this column. If a column has to pass a train, the train must halt, if necessary, till the column passes. The column which has precedence must yield it if the Commander, on seeing the orders of the other, finds it for the interest of the service. Dispositions for battle depend on the number, the kind, and quality of the troops opposed, on the nature of the ground, and on circumstances which it is impossible to anticipate; and therefore the general disposition is left to the judgment and discretion of Commanding Officers. In making an attack, the communications to the rear and for retreat should be secured, and the General should give beforehand all necessary orders to provide for that event. During the fight the officers and non-commissioned officers keep the men in the ranks, and enforce obedience if necessary. Soldiers should not be permitted to strip or rob the dead, nor even to assist the wounded, except by express permission, which is only to be given after the action is decided. The highest interest and most pressing duty is to win the victory, by winning which only can a proper care of the wounded be insured. Before the action, all the necessary arrangements are made for the transportation of the wounded. Ambulance-depots are established in the rear, and necessary instructions are given for the service of the ambulance-wagons and other means of removing the wounded. A General Commanding in the Field or a Department makes arrangements for the safe-keeping and reasonable comfort of his prisoners. For this purpose he may appoint a Provost Marshal to take charge of them, and place them under a guard already on duty, or detach a guard for the special service. The General gives no order exchanging prisoners, or releasing them, except under instructions from the Secretary of War. In emergencies admitting of no delay he may act upon his own authority, and give any order in relation to his prisoners the public interest may require, promptly reporting his proceedings to the War Department.

FIELD-STAFF.—A staff formerly carried by gunners in the field, and holding lighted matches for discharging cannon. It is no longer used.

FIELD STATE.—A statement made over to the Superior or Reviewing Officer on parade, showing the number of officers and men composing the troops, distinguishing those present and absent (on whatever account in the latter case), all under their respective headings.

FIELD-TELEGRAPHY.—The electric telegraph is a novel element of war. England was the first to apply it to military operations. During the siege of Sebastopol telegraphic lines were established by the allied armies, and later, during the Indian Mutiny, a first attempt was made to organize a field-telegraph, which succeeded admirably under the direction of the late Captain Stewart of the Bengal Engineers. In 1859 the French army was accompanied by a large *personnel* belonging to the civil telegraphic administration, whose duty was to establish a service during the marches. The war in America, and that between Austria and Prussia in 1866, showed convincingly the importance of such an introduction into military operations. Permanent lines on a large extent were established and worked by the troops; all those that existed in the zone of operations of the armies were seized. Trains of a special field-material followed each corps, to be used on the march, in cantonments, and even on the field of battle. In 1866 the Prussian and Austrian armies employed, to a great extent, telegraphic lines during the marches and maneuvers that preceded Sadowa. The war of 1870-1871 is another instance of the immense advantages that can be derived from the use of the electric telegraph when well organized and employed. During the latter end of the war, Manteuffel and Werder, operating in the East separately and on different lines, were able to combine their movements and to receive direct instructions from the headquarters at Versailles by means of the wire. The Telegraphic Department in time of war may be divided into two distinct branches. The first comprehends the seizure and use of all permanent lines existing in the country in which the operations are carried on, or, in the absence of these, the creation of new lines of the same kind. The influence of the telegraph is very great, as it enables the General in Command, as long as the opposing armies are concentrated, to transmit intelligence and directions between his headquarters and the rear of his army, or between himself and the Generals commanding wings. The organization and working of such lines should keep pace with the rapid transport by rail of troops and supplies. Whether already existing or newly created, it is considered as a general rule that within the zone of operations an army should exclusively dispose of all the lines indispensable for its correspondence, and that these should be carefully watched over, whilst those that are not necessary and might fall into the hands of the enemy should be destroyed. The second branch of this Department comprehends the transport, the establishment, and the working of mobile lines, known as the *field-telegraph.* These are used when the opposing armies are in presence of each other, and on an extended fron and in cases when concentrated action is essential to success. By the field-telegraph, *corps d'armée* are placed in intimate communication with each other, and are connected with their base of operations by means of the permanent lines. On the march the telegraph can easily be laid down as each column advances, and thus the Commander-in-Chief be placed in communication with the whole of his army. In certain cases, when circumstances permit of it, the field-telegraph, as was seen during the Indian Mutiny and later wars, can be brought on the battle-field, following closely the combatants. Lines of a light nature can move easily with armies in the field, and can subsequently be replaced by others of a more solid material, called *semi-permanent,* if communication is to be kept up for any length of time. Field, semi-permanent, and permanent telegraphs differ in materials and manner of laying. The *field-telegraph* should be of such a nature that it can be constructed or taken up at the same rate as an infantry regiment marches. The *semi-permanent telegraph* is constructed of more solid material and substantial wire; its weight, including the poles, should not exceed one ton per mile, and it should be of such a nature as to be laid at a rate of from 20 to 30 miles per day for every 100 men employed. The wires are suspended from poles, trees, or in any other convenient mode. The *permanent telegraph* can be constructed at the rate of 10 miles a day. There is a point below which the electric telegraph ceases to be advantageous over other modes of communicating intelligence, such as is carried on by signaling and by mounted orderlies. The handing-in, the transmitting, and the receiving of a telegram require a certain amount of time which may be longer than that necessary for a mounted orderly to cross the distance between the two places. The electric telegraph, therefore, should only be made use of for distances of eight miles and upwards. In England the military telegraph is worked by a branch of the Royal Engineers, of which there is one troop. At present this troop is composed of three officers and 245 non-commissioned officers and men; 12 wagons, each carrying 3 miles of insulated wire, rolled on 6 drums for paying-out, and iron rods for carrying over roads. A telegraph-troop forms 3 sections composed of 3 traveling offices, 3 general-service wagons, and 3 artificers' wagons. In time of war this branch of the service would be placed, in each army corps, under the immediate control of a Director of Telegraphs, with an assistant. His chief duty should be to keep up the communication between corps and divisions and headquarters. He should never be without one or two alternative lines, in case of accidents, and be always prepared to alter and adapt existing lines. Between important points there should be two or more separate lines, remembering that the sole value of telegraphs lies in their security. Every effort should be made to watch over the telegraphic lines used by an army in the field, and to destroy those of the enemy. Their destruction is easily executed; and this duty generally devolves on cavalry. It is sufficient to pull down the poles, and to cut them in several pieces, or carry away as much of the wire as possible; to destroy the insulators as well as the instruments and batteries found in telegraphic stations. A non-conducting wire, having the outward appearance of an ordinary wire, can be used also for destroy-

Fig. 1.

ing communication by splicing it to the electric wire in one or two places along the line. The result will be that all galvanic communication will be stopped, and it will be difficult to discover where the break exists. In telegraphy, as well as in the other branches of military art, it is important to be acquainted with the resources of the country, and to take as much advantage of these resources as is possible. These are obtained by means of reconnaissances, and note must be taken of the plan and direction of all existing lines, and the advantages that may accrue from them by connecting them with other stations; the number and kind of instruments used in the stations; whether the roads to be traversed by the army are planted with trees or posts on which the wires can be set up; and whether the neighboring woods can furnish timber for the posts.

Assuming that the reader is unacquainted with the details of telegraphy, we will briefly describe the construction and operation of a field-telegraph. It is from the action created in the battery that is first generated the electric current, which, in field-telegraphy, is made to traverse long or short distances through the conducting medium of metallic wires, and this current of electricity, so generated in the battery, and so conducted through the wires, is then, by means of the proper instruments, made to give out tangible signals, which, being arranged in the form of an alphabet, enables us to read or speak as it were from any great distance, and this instantaneously; for the electric current requires but a small fraction of a second's time to travel many hundreds of miles through the wires.

Where currents more powerful than can be produced by a single cell are required, additional cells are added by connecting either the copper or zinc pole of the first cell to the opposite pole of the next, and so on (Fig. 1); so that in a series of fifteen or twenty cells, if the unconnected pole of the cell at one end were copper, that pole would constitute the copper pole of the entire battery, and the unconnected zinc at the other end would be the zinc pole of the entire battery. By connecting the end of a wire of any length to the zinc or copper pole of such a battery, and its opposite end to the remaining pole, a much more powerful current would pass through the wire than if the battery consisted of but one cell. Telegraph Companies on their long lines use batteries of from twenty to one hundred cells each. To put the battery in operation, fill the glass jar about two thirds full of water; place the copper in the bottom so that it rests as nearly level as possible, and its wire passing straight upward at one side of the jar. Then drop about half a pound of sulphate of copper into the jar so the lumps will lie evenly on the bottom or around and on the copper. Then suspend the zinc so this battery depends very much upon the position in which the zinc is placed with reference to the copper. To get the most active effect, lower the zinc to within about an inch of the copper, taking care not to allow a contact between the two. To decrease the power and render the battery more constant or lasting, raise the zinc farther away from the copper. Mention is made of the use of wire as the means of conducting currents of electricity from one pole of a battery to any given point, and thence back to the opposite pole, making the "circuit," as it is called, complete. Certain substances are found to conduct electricity with more or less facility, and these substances are called conductors, while through other matter no currents whatever will pass. The latter class of substances are called non-conductors or insulating mediums. In telegraphy there are used as conductors, principally, copper, iron, brass, and platina. As insulation, gutta-percha, hard and soft rubber, glass, silk and cotton fiber, dry wood, bone and ivory. Iron in the shape of wire is usually employed for outside conductors, because of its durability, cheapness, and strength, although it is not as perfect a conductor as copper, which latter is generally used for all wires inside of buildings and offices. In conducting currents of electricity from one point to another, as in telegraphy, it is found necessary to use non-conduct-

Fig. 2.

that the body of the wheel is about two inches above the copper. As the battery does not at once begin to act in its fullest strength when newly set up, it is well to connect the copper with the zinc and leave it so for a few hours before using. This is done by fastening the wire from the copper into the screw-post of the zinc hanger, and will soon cause the battery to work up sufficiently to be ready for use. The battery should be kept supplied with enough sulphate of copper so that a blue color can always be seen in the liquid at the bottom of the jar, rising to within an inch of the lower surface of the suspended zinc. If it is found that the blue color rises higher than this, it is thereby indicated too much sulphate of copper is being used, and no more should be put in until the blue has receded almost to the very bottom of the jar. The latter state of the battery indicates that more sulphate of copper is required. Water should be from time to time added to that in the jar to replace the loss by evaporation. Once in two or three months it will be necessary to thoroughly clean the battery. Take out the zinc carefully; then the copper in the same manner; pour the liquid into a separate jar, leaving behind the oxide and dirt which may have gathered in the bottom of the jar. Wash the latter out completely, and return to it the clean liquid which it had in it before; put back the copper to its place; put in a few crystals of sulphate of copper; clean the zinc thoroughly by scraping and washing, and return it also to its place. The battery will then be in good order, and should not be disturbed excepting when necessary to clean it or add sulphate. The power of ors wherever a fastening of the wire is made, in order to prevent an escape of the fluid at these numerous points. For this purpose glass is principally used for outside wires, the glass "insulators" being first made fast to the pole or building, whereon the wire is to be suspended by means of a wooden pin, or "bracket," after which the wire is strung and tied to the glass with a short piece of iron "tie-wire." Inside of offices hard and soft rubber tubes are used where the wires pass through the windows, and the copper conducting-wires are usually covered with a coating of gutta-percha, or wrapped with a continuous covering of cotton or silk. The latter is principally used as a covering for the wires inside the finer instruments. For the handles or knobs to the various instruments which require manipulation, hard rubber is generally used. It is found that when one pole of a battery is connected with the earth, and the wire from the opposite pole carried to a point at any distance away, and also connected with the earth, the current will flow as readily as though the "circuit" had been made complete by the use of a return-wire. It is therefore shown that the earth is practically one vast conductor. This is principally due to the fact that moisture is everywhere present beneath the surface of the earth, and water itself is known to be a very fair conductor. Telegraph Companies make great practical use of earth-conduction by using it in all cases for their numerous lines, both long and short, thus saving the construction of a separate or return wire on every circuit. A careful reading of the foregoing will have enabled the soldier to understand how currents of electricity are generated and made to travel through space. The next feature of the study will be the means which are employed to make these currents transmit signals. The basis of the entire telegraphic apparatus is the electro-magnet and the transmitting "key" (Fig. 2). The electro-magnet is constructed as follows: Two bars of soft iron, having round heads of rubber or wood, thus making spools of each, are fastened together by means of a short flat bar of iron similarly soft. The round bars in the spools of the magnet are called the "cores." The flat connecting-bar at the back is called the "back armature," by telegraphers, to distinguish it from the movable piece in front, which is to be attracted to the "cores" or withdrawn by the spring, and which is called the armature. A silk- or cotton-covered wire is wound in continuous turns about the cores until a diameter of about an inch and a half is attained, and each core or spool of the magnet contains a great number of turns of the wire around it. Now, if a current of electricity be sent through this wire, it will, by its passing through the numerous turns, cause the iron cores within to become magnetic and to possess the power of attracting with considerable force any piece of iron brought near to their ends. The cores, being made of soft iron, will lose their magnetism and cease to exert any attractive power the moment the current ceases to flow. The actual power of the attractive force thus exerted is directly dependent upon the power of the battery which supplies the current, or, more properly speaking, upon the power of the current itself. Strong currents will cause the magnets to attract with a power of several pounds. Keys are simply a contrivance for making or breaking the contacts which control the passage of the current—a brass lever swung on a pivot, having a rubber handle which the operator grasps lightly with the thumb and forefinger. On pressing the lever downward, a platina point projecting under the lever is brought into contact with another platina point set into an insulation of rubber in the base of the key, so that there can be no electrical connection between them unless the key is pressed down, or "closed" as it is termed. A conducting wire being separated at any point, and one of its ends connected with the lever or base of the key, and the other end with the metal set into the rubber insulation, would convey the current while the key was closed, and cease to do so the moment it was opened. Platina is used at the points where the electrical contacts are made and broken because it does not readily fuse or tarnish. An extra lever at the side of the key is called the "circuit-breaker," and is used as a means of keeping the circuit closed when the hand of the operator is not on the key. When the circuit-breaker is pushed into its closed position it makes contact with a brass lip, which latter is fastened to the rubber along with the lower platina point. This, then, has the same effect as though the key was pressed downward and contact made at the points. Fig. 2 represents a magnet with its armature suspended from a spring, and connected with it by a wire, a battery, and a key. From what has now been explained it may be seen that when the key is closed a current from the battery will pass through the wire and magnet, and cause the latter to attract the armature, overcoming the resistance of the spring, and that the instant the key is opened the current will cease to flow, the magnet cease to attract, and the spring will instantly draw the armature back to its original position. In this way the armature is made to follow exactly the movements of the key, no matter at what distance they may be placed from each other, although in practice it is found that as the circuits are lengthened, more battery power and more delicate instruments are required than on short lines. The whole basis of the telegraph system is this duplication at one point, by the magnet and its armature, of the motions made on the key by the hand of the operator, at

Section of glass insulator, and manner of attaching to pole; B is a bracket, spiked to the pole, P; over the upper part of the bracket fits the glass, G. 12. Climbers. 13. Brockton Combination Line-vise. 14. Solder-pot. 15. Line-tapping Clamp, for use in establishing Temporary Offices.

another separate and distant point. During the first years of telegraphy, the Morse register was the only means employed to put into tangible form the signals transmitted over the wires. See *Telegraph*. The armature of the magnet is attached to a lever, and this lever, which swings on a pivot in the middle, is provided at the end with a pointed pin or screw, which is caused to press upwards against a strip of paper whenever the magnet attracts, and to return to its former position when the reverse is the case. (Fig. 3.) Meanwhile the paper is kept moving steadily forward, so that if the lever-pin is pressed against the paper for only an instant of time a short mark or *dot* appears pressed or embossed into the paper. If for a longer time, the mark would be proportionately longer, or a *dash*. If alternately, the marks would come consecutively, and have *spaces* between them. As the Morse alphabet consists entirely of dots, dashes, spaces, and extra-long dashes, the letters and numerals are easily made with these marks and their combinations. So that as the hand of the operator, on the key at a distant point, makes short or long strokes, dots, or dashes, or spaces, these same marks appear on the paper as it comes from the register, and, being based on the formation given by the Morse alphabet, are as easily understood by the receiving operator as though they appeared in the well-known Roman characters. After the telegraph had been in successful operation for several years, the operators began to discover that, with practice, they could more easily distinguish the dots and dashes by the clicking sounds that came from the instrument, when the lever responded to the signals, than they could read them from the paper. This was the beginning of what is called *reading by sound*. At the present time none are considered good operators who cannot read by sound, and there are comparatively few registers employed in the United States.

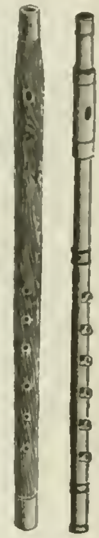
Having set up the battery, connect, as shown in the cut, one wire from the copper pole of the battery to one of the brass binding-posts of the instrument, and one wire from the zinc pole to the remaining binding-post; screw down the instrument firmly to the table with the screw in the base, as its best sound is thereby produced. See that none of the screws are loose in their places, and that the armature lever, which is the speaking tongue of the telegraph, plays freely, with a movement of about one sixteenth of an inch. The spring, which draws the armature-lever upwards, and is called the adjustment, should only be set at sufficient tension to raise the lever when no current is passing through the magnets. If drawn too tightly, the spring will not allow the armature to respond to the attractions of the magnet. When the instrument is not in use, leave the circuit-breaker of the key open so that the battery will not be in action, and its power accordingly economized. See that the platina points of the key are kept clean from dirt or dust, thus preventing imperfect contacts from being made. The key is provided with screws for the purpose of regulating its play to suit the hand of the operator, and to regulate also the pressure of the spring beneath it, for the same purpose. The best way to acquire the habit of correct Morse writing in the start is by practicing with another student at the same instrument, one at making letters, while the other by listening endeavors to name them. This is excellent practice for both; it is the beginning of sound-reading on the part of the one who names the letters, while the one who writes on the key *must* make the signals distinctly and correctly or they cannot possibly be distinguished by the other. Start rightly, and practice will soon make perfection of skill. No mental effort whatever is required of the practical operator to construct a Morse letter the moment his eyes come to it. And in transmitting messages he transmits the right signals in a continuous stream with as little effort or thought as the accomplished penman rapidly writes the words of a manuscript. The click of an instrument is as easily understood by a "sound-operator" who has had an experience of a year or two as his own language spoken in the clearest of accents. After two or three weeks of practice together over one instrument, two persons should be able to read each other's writing slowly, and should also have become familiar with the instruments, battery, and the principles of their operation. Separate practice over a short line between different rooms or buildings may then with advantage begin, each student having an instrument connected at his own end of the wire, and all communication between them necessarily being made by telegraph. According to the length of line between the two instruments, two or more cells of battery, arranged in series, will be required to operate in this way. Connect instruments and battery as shown in Fig. 4. The return-circuit may be made either by a continuous wire, as indicated, or by connection with the earth at each end, G G. For wires of but a short distance in length, the return-wire is best; for out-door lines of more than a few hundred feet in length use ground-wires, as earth-connections are called. To make a ground-wire, connect a wire to a plate or sheet of metal, zinc, iron, or tin; bury the latter in moist earth. The plate of metal should present not less than three square feet of surface. Gas and water pipes are, however, the best for this attachment, and whenever they are within reach should be used instead of buried plates in the earth. In running an out-door wire between points at any distance apart, it should be insulated (by using glass or rubber insulators) from all direct contact with buildings, posts, or trees. This prevents "escape" of the current, by which it would otherwise be diverted from its proper course through both of the instruments, and reaching the earth by a shorter route, would circulate to its opposite pole in the battery without having any effect whatever on the distant apparatus. To make a joint or splice in wire, brighten the ends by scraping them, and twist each wire around the other as closely and firmly as possible, so that no strain will draw them apart. In running wires inside of a building, use insulated copper wire covered either with cotton or gutta-percha; fasten it in place with small staples or tacks, but in doing so be careful not to allow the covering to be opened or stripped from the wire, nor to allow the latter to come in contact with gas or water pipes, or metal posts. In the beginning, when two persons are first practicing over a short wire, arranged as described, ordinary conversation carried on by telegraph is as good a means of practice, both at sending and at reading, as anything else. Then proceed with alternately sending printed matter from newspapers or books and copying it with a pen or pencil from the instrument by sound as the other sends it. As each improves, both in reading by sound and in sending plainly, this will become very pleasant and interesting occupation. The more important telegraph implements, as manufactured by Messrs. L. G. Tillotson and Company, the leading Government Contractors in America, are shown in the full-page engraving. See *Telegraph*.

FIELD-TRAIN.—A Department of the Royal Artillery, consisting of Commissaries and Conductors of Stores, responsible for the safe custody of the ammunition, for the formation of proper depots of shot, etc., between the front and the base of operations, and that a due proportion shall be constantly at the service of each gun during an engagement.

FIELD-WORKS.—Field-works may be enumerated under three heads. 1st. Those which, being secure on the flanks and in the rear, are assailable only in front. 2d. Those which are assailable in front and on the flanks. 3d. Those which are assailable on all sides. The plan of the works of the first class, when the front to be defended is of very limited extent, may be a simple *right line*. From this line only a front or direct fire can be brought to bear on the assailant in his advance, and when he attains the ditch, the fire of the parapet passing over his head, he is in a sheltered dead space where he can leisurely take his measures to assault the parapet. For extended fronts a flanked disposition more or less perfect can be obtained, from which cross as well as direct fire can be brought to bear on the advance of the assailant. The most simple combination for this object is the *crémaillère* or *serrated line*, which consists of a broken line formed of long and short branches perpendicular to each other. The salient angles are protected by a cross-fire, as well as a portion of the ditch in front of the salients; but the portion of the ditch at each re-entering angle is a dead-space, not being reached by the fire of the parapet. The plan of works of the second class admits of great variety, depending on the extent of the position. The most simple is that of a work of only two faces, the salient being towards the assailant's line of approach. This work is termed a *redan*. The faces should receive such direction as to sweep the approaches to the flanks of the position. As many pieces as possible are placed in the salient, and others disposed along the faces in the most commanding positions for sweeping the ground in their front. The angle formed at the salient by the faces should never be less than 60°. When the flank approaches extend somewhat to the rear, a flank is added to each face of the redan; it then becomes a *lunette*. The flanks receive such directions as will sweep by their fire that portion of the flank-approaches which cannot be reached from the faces except by a very oblique fire. The artillery is placed in position at the salients, in each of which is a pan-coupée. The works comprised in this class are termed inclosed works, as, being assailable on all sides, they must, for security, present a complete line throughout to any assault. These works may be divided into three orders: 1st. *Polygonal works*, or *redoubts*; 2d. *Tenailled works*, or *star-forts*; 3d. *Bastioned works*.

The defense of inclosed works demands that every point of the parapet should be guarded, at the moment of assault, either by cannon or musketry. The troops may be drawn up for the defense either in one, two, or three ranks; and there should, moreover, be a reserve proportioned to the importance attached to the work. The free interior space, denominated the *terre-plein*, or *parade*, should be sufficiently great to lodge the troops, with the cannon and its accessories, and will therefore depend on the nature of the defense. The following data will aid to regulate this point. Each man will occupy one yard, linear measure, along the interior crest, and each cannon from five to six yards. The space requisite to lodge each man is one and a half square yards; and about sixty square yards should be allowed for each gun. Besides this space an allowance must be made for the *traverses*, to cover an outlet, to screen the troops from a reverse or an enfilading fire, etc.; and for powder-magazines when they are not placed in the traverses. The area occupied by a traverse will depend on its dimensions, and cannot be fixed beforehand; that allowed for a magazine for three or four cannon may be estimated at fifteen or twenty square yards. As a field-fort must rely entirely on its own strength, it should be constructed with such care that the enemy will be forced to abandon an attempt to storm it, and be obliged to resort to the method of regular approaches used in the attack of permanent works. To effect this, all the ground around the fort, within the range of cannon, should offer no shelter to the enemy from its fire; the ditches should be flanked throughout; and the relief be so great as to preclude every attempt at scaling the work. See *Bastioned Forts*, *Field-fortification*, *Inclosed Works*, *Lunette*, *Priest-cap*, *Redan*, *Redoubt*, *Star-forts*, and *Swallow-tail*.

FIFE.—An ancient wind-instrument of military music, in which the melody is produced by blowing through a hole in a reed or tube, while the escape of air is regulated by the fingers stopping or opening a number of other holes in different parts of the pipe. It has a compass of two octaves, from D on the fourth line of the treble clef to D above in altissimo. The fife figures in the sculptured memorials of the Argonautic expedition, and from that time to this has maintained its place as a simple yet effective instrument for martial purposes. It was common with English troops till the reign of James I., but was then discontinued, to be reintroduced by the Duke of Cumberland at the siege of Maestricht in 1747. It is a universal favorite in the Navy, and many a stirring air on drums and fifes has cheered the sailor to deeds of daring.



FIFE MAJOR.—The chief or superintendent of the fifers of a regiment. In the English infantry there is a fifer to each company, and a Fife Major to each battalion, the former receiving the daily pay of 1*s*. 1*d*., the latter, who is a non-commissioned officer, 1*s*. 11*d*.

FIFER.—One who plays the fife. In the United States army there is one fifer allowed to each company of the infantry. Fifers are also employed aboard men-of-war and in the Marine Corps.

FIFTEEN-INCH GUN.—A smooth-bore, muzzle-loading cast-iron gun, mounted on a front- or center-pintle carriage, used in the United States sea-coast service. The following tables exhibit the principal weights, dimensions, and ranges of the gun:

DESIGNATION.	Lbs.	Inch.
Caliber	....	15
Weight	49,000	....
Preponderance	00	....
Length of piece	....	190
Length of bore (calibers)	....	....
Maximum diameter	....	48
Minimum diameter	....	25
Windage	....	0.13
Charge (mammoth or hexagonal powder) for shot	100	....
" for shell	60	....
Solid shot	450	....
Shell (unfilled)	330	....
Initial velocity (feet)	....	....
Weight of top-carriage	5,800	....
Weight of chassis	15,450	....
Carriage—wrought-iron (chassis with two air-cylinders to check recoil)	....	....

Ranges in Yards.

SHOT.		SHELL.			
Elevation.	Range.	Elevation.	Range.	Time of flight.	CHARGE.
Degs.	Yards.	Degs.	Yards.	Secs.	
1	769	1	600	1.44	100 lbs. of mammoth powder for solid shot, and 60 lbs. for shell.
2	1,332	2	1,073	2.79	
3	1,819	3	1,467	4.1	
4	2,235	4	1,800	5.28	To fill shell: 12 lbs. of mortar-powder.
5	2,601	5	2,094	6.44	
6	2,926	6	2,355	7.58	
7	3,221	7	2,590	8.67	Pressure per square inch, average 19,500 lbs.
8	3,491	8	2,804	9.68	
9	3,735	9	3,000	10.69	
10	3,959	10	3,171	11.63	Length of cartridge 100 lbs.=30 inches. 60 lbs.=18 inches.
15	4,890	15	3,916	16.30	
20	5,579	20	4,458	20.52	

The piece admits of 25 degrees elevation and 6 degrees depression. The platform is a permanent portion of the work. The top-carriage is the same; the chassis alone differs in the front-pintle and center-pintle carriages. The weight of the front-pintle chassis, including geared traverse-wheels is, 17,000 pounds. There are two kinds of geared traverse-wheels, differing however only in height and weight. The axis of the trunnions of the gun mounted on the higher is 8 feet 5.25 inches above the pintle-block, and 10 feet 11.25

inches above the terre-plein. Upon the other carriage it is 7 feet 2.25 inches above the pintle-block, and 9 feet 5.25 inches above the terre-plein. The front axle of the top-carriage is not eccentric; the rear one is. The front part of the sole of each shoe is cut away to a point a few inches in rear of the front axle, and to a depth of about half an inch. When the rear wheels are out of gear, the front wheels do not touch the chassis-rails; but when the rear wheels are thrown into gear, the rear part of the carriage is slightly raised, and the front part of the carriage is, in consequence of the soles being cut away, lowered; the front wheels then touch the chassis-rails and support the weight of the front part of the carriage, and the whole moves with rolling friction upon the front and rear truck-wheels. The wheels are out of gear when the gun is fired; the recoil is then on sliding friction. The front axle is furnished at each end with a brass sleeve, to which the counterpoise handspike is firmly attached. A pawl is attached to the handspike, and engages into ratchets in the truck-wheels. Bearing down upon the handspikes forces the wheels to turn, and communicates motion to the carriage. The handspike pawls are engaged in the ratchet of the truck-wheels only when it is desired to give motion to the carriage; at all other times they must be kept clear of the ratchets. To prevent the rear truck-wheels of the carriage from working out of gear while the gun is being run from battery, or jumping in gear when the gun is fired, pawls are provided for locking the rear axle. The elevation is given by means of the elevating arc. With a well-instructed detachment, the 15 inch gun can be fired twelve times in an hour, allowing time for deliberate pointing. The carriage and chassis for the front and center pintle have the same dimensions, viz.:

Length of chassis .... 19 feet 7 inches.
Width of chassis .... 5 feet 2 inches.
Depth of chassis-rail....... 1 foot 8 inches.
Length of carriage........ 8 feet 8 inches.
Inclination of chassis-rails. . 3 degrees.

See *Cast-iron Guns* and *Ordnance*.

FIGHT.—A struggle for victory, either between individuals or between armies, ships or navies. A duel is called a single fight or combat. A running fight is one in which the enemy is continually chased. To *fight it out* is to continue the contest until one side or the other gets the better. The French express it by *se battre à outrance*. See *Battle*.

FIGURE.—In fortification, the plan of any fortified place, or the interior polygon. Of this there are two sorts, regular and irregular. See *Field-works*.

FIGURE OF MERIT.—The figure denoting the efficiency of the shooting of a squad, a company, or battalion. The figure of merit is formed as follows: Average points obtained in the first and second periods. *The aggregate points to be divided by the number of men who commenced the first period.* Average points obtained in the volley-firing. Minus percentage of third-class shots at final classification.

Infantry.

	Very good.	Good.	Moderate.	When under.
Average points obtained in first and second periods together......	75	70	65	65
Average points obtained in volley-firing........	17	15	14	11
Percentage of third-class shots at final classification (*minus*).	8	12	16	When over. 16
Figure of merit	85	75	65	65
Average points in independent firing	18	16	15	15
Average points in the skirmishing....... ...	9	8	6	6

FILE.—1. File, in a military sense, is used to signify any line of men standing directly behind each other, as *rank* refers to men standing beside one another. In ordinary formations of the present day a battalion stands two deep, or in two ranks—front and rear—wherefore a file consists of two men. Sometimes, however, the battalion may be formed much more solidly, as in a square, when the file comprises a far larger number. The number of files in a company describes its width, as the number of ranks does its depth; thus, 100 men in "fours deep" would be spoken of as 25 files in 4 ranks.

2. The Ordnance Department employs one skilled file-cutter at the National Armory, who is kept constantly employed in recutting worn-out files and in making special files for certain classes of work required in the fabrication of small-arms. All the rotary files used in the establishment are also cut there. Since the introduction of "gun-steel" or Bessemer steel as the material for many of the components of arms, a good many files are used which are "new cut" or "skew cut." This "new" or "skew" cut is one in which the first course, or *over-cut*, is a light cut with small horizontal obliquity, while the second course, or *up-cut*, is coarser, with great horizontal obliquity. This method of cutting is excellent for a finishing-file, and is very popular among armorers on account of the ease of manipulation and freedom from clogging, as well as the smoothness of the surface produced. But, unless the quality of the milling be excellent, these files do not produce good results except with a great expenditure of time, a thing piece-workmen especially desire to avoid. Files are used upon surfaces of all kinds. Rasps are used upon those materials whose particles possess less resisting power, and are chiefly employed for rapid work. They are more used by workers in wood, soft metals, and leather than are files. The general effects of rubbing a file or rasp upon the surface of metal, wood, ivory, leather, or other material is to smooth it and change its form and dimensions. The abrasive effect consists in cutting from the surface small shavings or particles and in gradually reducing the mass. Therefore files are only used for shaping and smoothing small pieces, or in finishing surfaces that are already of approximate figure. The file usually follows the work of the lathe, the planer, the milling-machine, or the profiling-machine. In the natural motion of filing, the tendency is to impart to the file a somewhat circular motion, the articulation or joints of the arms and hands acting as centers of motion. It would seem that this kind of motion with a convex file should produce concavities in the work, whereas the real effect is to give a slight convexity to the work, due to the rocking motion caused by the work acting as a kind of fulcrum, except where the file is handled by a skillful manipulator. Every filer should aim to have his file, during the stroke, depart from a strait line just enough to bring it into contact with the desired portion of the work. The filing of round or curved surfaces requires that the strokes should be so blended as to produce the best effect. This class of filing depends a good deal upon the experience and eye of the workman, but is not so difficult as absolutely *flat* filing.

To the uninitiated the operation of filing seems to be a very simple matter, and one that can easily be attained by any person. On the contrary, the art of *filing well* is one which requires a great deal of skill and long-continued practice, as well as thought and judgment. It is true that in many shops there can be found filers who possess neither skill nor judgment, but who, from long practice on some special classes of work, have become known as filers. Such persons, however, are not, and do not deserve to be, called "good filers." It is also true that this same class of inferior workmen generally claim to be, and doubtless believe that they are, excellent filers. A rigid system of inspection and a persistency in pointing out the multitudinous defects of their "finished work" (so called) would result in instilling into their minds a belief that they were being persecuted, and

that the Foreman or Superintendent was "down on them, and was seeking opportunity to find fault with their work." Very ignorant filers, as well as other classes of mechanics, artisans, and even professional men, are often as bigoted and self-conceited as they are unskillful and opinionated. With many of them it is an almost hopeless task to attempt to eradicate slovenliness in their manner of filing, especially after years of practice in such methods. Examples are numerous where men who have been filing for years do not even "know how to hold their files." Gun-makers, Master-mechanics, and Superintendents of manufacturing establishments where a great deal of filing is required, all know the difficulty of obtaining good filers. The supply is not equal to the demand, and the inequality increases yearly, and has done so since the practical abolition of the apprentice system in this country. The advent of planers, shaping-machines, trimming-machines, shaving-machines, and milling-machines has greatly diminished the amount of filing formerly required in the machine and gun shops; and filing, in its widest sense, is apparently about to be remanded to the category of the "lost arts." Boys and young men go to work on a machine, and find that in a few weeks or months they can earn fair pay without any previous study or apprenticeship; consequently it is not strange that they are loth to spend several years of apprenticeship in endeavoring to learn a trade which, when obtained, will bring little or no advance of a remuneration. Again, Proprietors of machine-shops are in such haste to get rich that they do not wish to employ any but skilled workmen, hence they refuse to be "bothered" with teaching boys who will probably leave their shops as soon as they have learned their trade. The old filers who have learned the trade regularly by a toilsome apprenticeship are gradually dying off, and no new brood is now being educated to supply their places. Hence the complaint is constantly heard that we cannot find enough good filers. How this evil is to be remedied is not within the province of this article, and the writers merely call attention to the fact.

There are very few mechanical operations that present greater difficulties than that of filing well. If a planer be used, the work is firmly fastened to the movable bed-plate, which has a motion of translation along fixed guide-rails, and passes under a tool attached to a tool-post with an automatic transverse feed-motion. If a shaper be employed, the work is keyed to the immovable bed and the tool has a motion of translation and rotation, the former governed by fixed guides and the latter by a screw. In neither of the cases above cited does the accuracy of the work depend upon the workman's skill after the machine has been set and put in motion. But in filing, the "guiding principle" of the machine is absent, and the accuracy of the work depends upon the constant care, skill, and judgment of the man. To produce a "*true flat surface*" upon narrow work is an excellent test in filing. One would naturally suppose that a file the points of whose teeth lie in the surface of a single plane is all that is required to do the work. Even if the *side* of the file was a *perfectly* plane surface—which it never is—it would be necessary to move it in parallel straight lines across the work to produce the required effect. Supposing this operation possible, the pressure applied at the ends of the file, as is usual, would spring the file and produce a concavity on its under surface, which in turn would naturally round the work. To obviate this defect the file should have its sides slightly convex. The greater the convexity of the file the fewer teeth that come in contact with the surface and the better will the file cut or bite, provided the pressure remains constant. The convexity is sometimes given by slightly curving or tapering the sides from about the middle to the point. A better way, perhaps, is to have the gradual curvature extend from the heel to the point. The advantages of the convexity are plainly seen when the attempt is made to produce an approximately true plane surface. The straight-edge or surface-plate will show the points on the surface, which are a little higher than the rest, and without a file with convexity it is impossible to touch the exact spot desired and no other. The full-page engraving represents the New American File Company's cuts of files and rasps. This Company use the Bernot machines for cutting, and the accuracy and uniformity of cut in all their product is unequaled by that produced by any other methods, either by hand or otherwise. See *Rasp.*

FILE LEADER.—The soldier placed in front of any file, or the man who is to cover all those who stand directly in the rear of him, and by whom they are to be guided in all their movements.

FILEY SYSTEM OF FORTIFICATION.—In this system the curtain is replaced by a bastion or mezalectre, whose flanks defend the collateral works. There are cavaliers on the curtains, retrenchments in the bastions, tenailles between the bastions and mezalectre, ravelins, counter-guards, and covered-way. The great defect of this system is that the enemy can attack the mezalectre instead of the bastions

FILIBEG—FILLIBEG.—A little plaid; a kilt or a dress reaching nearly to the knees, worn in the Highlands of Scotland, and by the soldiers of Highland regiments in the British service.

FILIBUSTERS—FILLIBUSTERS.—Another name for piratical adventurers. Recently it has become familiar to English ears as the designation of certain lawless adventurers belonging to the United States, who have attempted violently to possess themselves of various countries in North America. The plea urged by these persons has generally been that such countries were a prey to anarchy and oppression, and could only attain to prosperity by annexation to the United States, and the introduction of democratic institutions—among which, strange to say, slavery stands prominent. The most notorious of these filibusters was the late William Walker, whose expedition against Nicaragua in 1855 was so far successful that he kept his ground in that country for nearly two years. At last he was driven out by a combination of the various States of Central America. He was subsequently captured and shot, September 12, 1860, at Truxillo, in Central America, in the course of another piratical expedition.

FILINGS.—In tactics, the numerous movements to the front, to the rear, or to the flanks, by files.

FILLET.—1. A molding used on cannon of old form. 2. In Heraldry, an ordinary which, according to Guillim, contains the fourth part of the chief. 3. A head-covering that frequently replaced the helmet among the Assyrio-Babylonian archers.

FIMBRIATED.—A term in Heraldry, said of any ordinary having a narrow border or edging of another tincture.

FINAL VELOCITY.—In gunnery, the technical term for the uniform velocity which a projectile would acquire in falling through an indefinite height in the air. A body falling in *vacuo* is uniformly accelerated, its velocity being continually increased. In the atmosphere the case is different. Since the resistance of the air increases with some power of the velocity greater than the square, it follows that at some point in the descent the retardation becomes equal to the acceleration, and the body will move with uniform velocity. This is called *final velocity*, and is one of the most important elements in the theory of projectiles. Other things being equal, that projectile is best which has the greatest final velocity. See *Form of Projectile*, *Projectiles*, and *Velocity*.

FINDING.—Before a Court-Martial deliberates upon the judgment, the Judge Advocate reads over the whole proceedings of the Court; he then collects the votes of each member, beginning with the youngest. The best mode of doing so is by slips of paper. The Articles of War require a majority in all cases, and in case of sentence of death two thirds. It is not necessary to find a *general* verdict of guilt or acquittal upon the whole of every charge. The Court may find a prisoner guilty of part of a charge, and acquit him of the remainder, and render sentence according to their finding. This is a *special* verdict.

FINING-FORGE.—An open hearth with a blast by which iron is freed of impurities or foreign matters. Cast-iron is thus rendered malleable by the removal of carbon, etc.

FINISHING.—The final operation in the fabrication of cast guns. When the casting has become cool it is hoisted out from the pit, the flask being first taken off. The molding composition adhering to the interior or exterior is removed as far as practicable by scrapers and chisels. The casting is then placed in a machine called a heading-lathe, shown in Fig. 1, where the greater part of the surplus metal of the chase is removed and the sinking-head is cut off. From the latter a ring is also cut off next to the muzzle of the gun for the purpose of testing the initial strain, and from which specimens are afterwards taken for tenacity and density. To place the gun in the lathe, the square knob of the cascabel is fitted into the chuck attached to the machinery, which revolves the gun, while the sinking-head is introduced into the "bonnet" which revolves in its bearing at the other extremity of the lathe. Both of these supports are provided with adjustable screws by means of which the gun is centered from the bore, as it sometimes happens that the axis of the bore and casting do not coincide. The gun being centered, all the measurements necessary for a proper commencement of the turning are made.

The turning of the gun commences near the muzzle. The rest in which the turning-tool is placed is so constructed that it can be moved either parallel to or at right angles to the axis of the gun. The tool is brought in contact with the surface of the gun at the desired point, the metal being turned off as the gun revolves. In this way a series of narrow cuts are made in the chase at short intervals, extending in depth to within about two inches of the required exterior diameter of the gun. The intervening rings are then broken out with wedges, and the portion of the chase next the muzzle is turned down to the finished dimensions. Meanwhile the cylindrical part of the cascabel is turned down slightly to form, with the finished part of the chase, bearings for the gun when transferred to the boring-lathe. The cuts at the muzzle for removing the sinking-head and test-ring are next made. When these cuts have reached a sufficient depth to admit of the separation, the gun is taken out of the lathe and placed upon skids and the bonnet is removed from the sinking-head. The ring and head together are

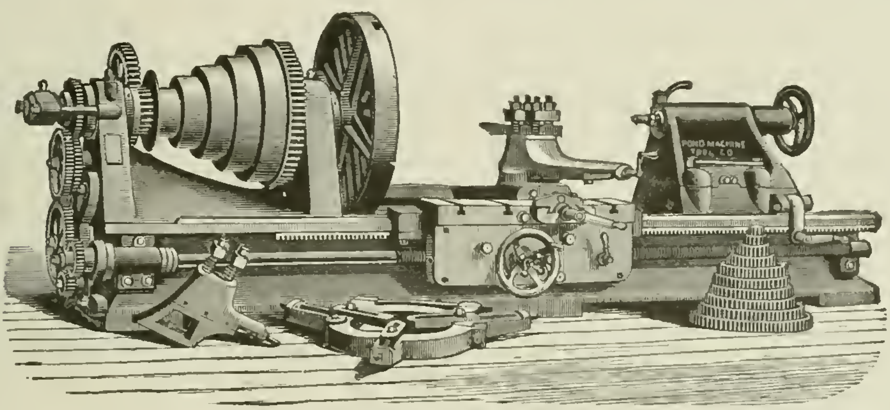

Fig. 1.

tered and held firmly in place. The breech is adjusted by placing a sharp-pointed instrument in the tool-rest and bringing it in contact with the surface of the casting near the maximum diameter, and, while turning the gun, the screws in the chuck are moved until coincidence of the line around the gun is obtained. At the muzzle a bar of iron is laid upon blocks so that it shall be just inside the bore and nearly in contact with the interior surface. As the gun turns, the distance between this point and the metal of the bore is observed and equalized approximately by the screws in the bonnet.

A wooden disk, turned to fit the bore accurately, bearing a string attached to its center, is then pushed to the bottom of the bore and made to assume a position in a plane perpendicular to its axis. The string from the center of the disk is long enough to reach some distance outside the muzzle, the outer end being made fast to an upright at the same height as the inner end or center of the disk. The string is now stretched perfectly taut and the gun again turned, a square being placed upon blocks about one foot in front of the muzzle close to the string, and, as the gun revolves, the distance, if any, which the string deviates from the square is observed and corrected by again moving the screws in the bonnet. When properly centered, the string will remain in the same position in the square and be the same distance from the interior surface of the gun throughout an entire revolution, showing that the axes of the gun and lathe coincide. With the hollow-cast gun it is necessary that it should then separated from the gun by inserting wedges at the muzzle, and the ring is afterwards wedged off from the head. The gun is next placed in the boring-lathe, in which it is supported by bearings at the chase and neck of cascabel. Its rotation in the lathe is effected by securing the square knob of the cascabel in the chuck attached to the revolving machinery, in the same manner as in the heading-lathe.

To adjust the gun the boring-rod is first introduced a short distance into the bore, and the space between its exterior surfaces and the gun at the muzzle is observed. For this purpose a thin wooden gauge is used, pointed at one end and having a notch at the other, which takes the outer surface of the gun at the muzzle —the gauge being laid on the face of the muzzle and therefore perpendicular to the axis of the bore. As the gun revolves the distance above, below, and on either side is observed, verifying the concentricity of the axis of the gun at the muzzle. The adjustment is completed at the breech by slackening the bolts of the cascabel bearing, leaving it free to move on the ways; and should any lateral motion be perceptible, it is corrected by adjusting the screws in the chuck, after which the concentricity is complete from breech to muzzle.

In boring, the tools or cutters are fitted into a cylindrical block called a "head," which is secured to the end of the boring-rod. As the gun revolves in the lathe, the boring-rod is made to advance by machinery until the cutters reach the bottom of the cylindrical part of the bore. From three to five cuts are usually required to secure a perfectly straight bore and enlarge it to its required diameter; the last one being made with a finishing-tool or reamer. The bottom of the bore is then finished with tools of the required shape.

During the process of boring the turning continues, and the exterior is finished except the trunnion section and the extremity of the breech where the cascabel attaches. The cascabel is turned down in front of the bearing so that it can be broken off when no longer required. To insure a smooth surface in the bore, the work upon the exterior of the gun is suspended while the finishing tools are being used.

The boring being completed, the dimensions of the bore of the gun are verified before removing it from the lathe. If found to be correct, the gun is removed and placed in the trunnion-lathe, where the trunnions are turned down to the finished dimensions. When adjusted in this lathe the axis of the gun is in a horizontal plane, the cascabel being supported by the breech-center, and the chase by the muzzle-bearing. The trunnion-head consists of a hollow shaft in which are located the cutters for turning the trunnions. It is supported upon bearings which rest upon ways at right angles to the axis of the gun. These bearings are of such a height as to bring the axes of the trunnion-head and gun in the same horizontal plane.

In turning the trunnions the gun remains stationary while the trunnion-head revolves about the trunnion. The cylindrical surface is first finished, the shaft moving towards the gun and its speed being regulated as circumstances require. To finish the face a broad cutter is used which removes a thin chip nearly equal in width to the semi-diameter of the trunnion. A small spur is left by this tool at the center of the trunnion which is afterward chipped off by hand. When one trunnion is finished, the gun is turned over and the other is finished in the same manner.

The metal in excess between the trunnions is removed by the planing-machine (Fig. 2), which is placed on the side of the lathe opposite the trunnion-head. This machine is so arranged that the bar in which the cutter is secured moves forward and back in a horizontal plane, carrying the cutter over that portion of the gun between the trunnions which has not been turned down. The cutter works upon a pivot in the bar, by means of which it cuts only while moving to the rear, the gun being turned the width of the cut after each passage of the planing-bar. The proper direction is given to the cutter by means of a guide attached to the planing-bar which moves in a groove of the required curvature.

After the planing is finished, the gun is removed

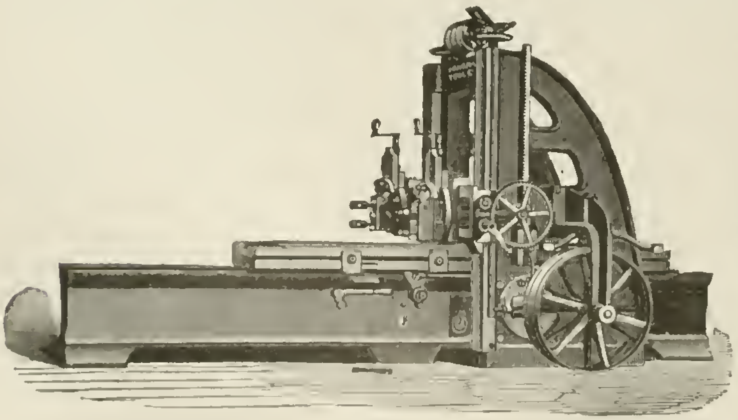

Fig. 2.

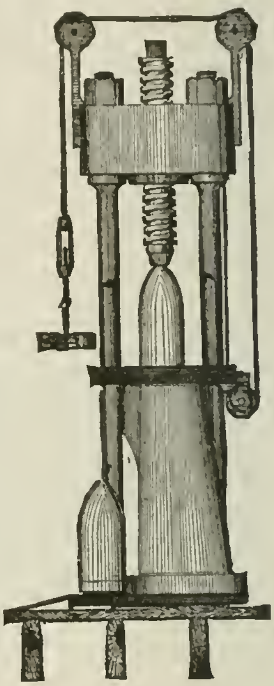
from the lathe, placed upon skids, and the cascabel is broken off. The breech, rimbases, and sight-mass are then finished by chipping off the surplus metal by hand. The vent is usually drilled by means of a hand drill arranged to work in an iron frame firmly secured to the gun. See *Lathe, Ordnance, Rodman Gun*, and *Turning*.

FINISHING PRESS.—This machine, employed in the fabrication of projectiles, as shown in the drawing, consists of a steel die, supported on a hollow iron platform resting upon the head of an hydraulic ram which is worked by a steam pump. On the left of the press is a handle for opening the valve to allow the admission of the water to the cylinder, and an automatic device for closing it and opening the valve for the escape, when the ram has reached its proper stroke. There are four iron guides for the hollow platform, connected at the top by an iron cross-head, through the center of which passes a heavy screw; the end of the screw is hollowed out to the shape of the head of the shot, for which it forms a support. Iron tongs are used for raising the shot from the floor to its seat, and these are raised and lowered by the movement of the machine itself. Two workmen are required for the machine, and two cuts are taken on each shot; the smaller die being the true size of the shot, and the other slightly larger. Supposing one shot to have been fitted into the die for the short length turned down in the lathe and its head inserted in the end of the screw, another is stood upright on the floor. One workman quickly opens the valve, while the other guides the descending tongs over the head of the shot below, as the hollow platform and die move upward. When the tongs have reached the center of the shot below they are clamped. As soon as the die has passed over the cylindrical part of the shot, the latter falls through the hollow platform into sawdust below; the automatic device then releases the ram, which descends,



and raises the tongs with the shot which is attached, and which is guided into its seat by the workmen. With this machine a thousand shot can be turned out per day. The dies, which are made of American steel, will last for about 1000 shot without resetting. The same operation is oftentimes performed in part or entirely in the lathe, but is very much less rapid than that just described. See *Fabrication of Projectiles*.

FIRE.—1. Artillery-fires are distinguished by the manner in which the projectile strikes the object, as *direct*, *ricochet*, *rolling*, and *plunging* fires; by the nature of the projectile, as *solid shot*, *shell*, *shrapnel*, *grape*, and *canister* fires; and by the angle of elevation, as *horizontal fire*, or the fire of guns and howitzers under low angles of elevation, and *vertical* fires, or the fire of mortars under high angles of elevation. A fire is said to be *direct* when the projectile hits its object before striking any intermediate object, as the surface of the ground, or water. This species of fire is employed where great penetration is required, as the force of the projectile is not diminished by previous impact; it is necessarily employed for spherical-case shot, and for rifle-cannon projectiles, which, from their form, are liable to be deflected by previously striking a resisting substance; it is also used for all field-cannon projectiles, when the nature of the ground does not insure a regular rebound. To point a piece in direct fire, bring the line of sight to bear upon the object, and then elevate the piece according to the distance. When a projectile strikes the ground or water under a small angle or fall, it penetrates obliquely to a certain distance, and is then reflected at an angle greater than the angle of fall; the reason for this is that the projectile in forming the furrow loses a portion of its velocity, making the distance from A (Fig. 1), the point at which it enters the ground, to C, or the vertical drawn through the deepest point, greater than the distance from C to D, the point where it leaves the ground. As this recurs every time the projectile strikes the ground, it follows that the trajectory is made up of a series of rebounds, or *ricochets*, each one shorter and more curved than the preceding one. The number, shape, and extent of the ricochets depend on the nature of the surface struck, the initial velocity, shape, size, and density of the projectile, and on the angle of fall. A spherical projectile ricochets well on smooth water, when the angle of fall is less than 8°; but if the surface of the water be rough very little dependence can be placed on the extent of the ricochet. In general, those projectiles which present a uniform surface and have the least penetrating power are most suitable for ricochet-firing; hence large shells fired with small charges are more suitable than solid shot, and round projectiles more suitable than those of an oblong form. The distance at which the larger-size shells will ricochet on water is about 3000 yards, the axis of the piece being horizontal and near the water. Ricochet-fire is employed in siege-operations to attain the face of a work in flank, or in reverse (Fig. 2), and on the field or on water when the object is large and its distance is not accurately known. The character of ricochet-fire is determined by the angle of fall, or the angle included between the tangent of the trajectory and horizon at the point of fall. There are two kinds of ricochet-fire—the *flattened*, in which the angle of fall is between 2° and 4°; and the *curvated*, in which the angle of fall is between 6° and 15°. The principal pieces employed in ricochet-fire in siege operations are the 8-inch howitzer and the 8- and 10-inch common mortars; the first two may be used when the angle of fall is less than 10°, and the 10-inch mortar when the angle of fall is less than 15°. With these pieces the limit of ricochet is about 600 yards. Solid shot should not be used in ricochet fire for any distance less than 200 yards, as it would then be necessary to diminish its velocity so much as to destroy its percussive effect. In ricochet-firing against troops in the open field the angle of fall should not exceed 3°. In enfilading the face of a work, the form of the trajectory and point of fall should be such that the projectile will strike the surface of the terre-plein the greatest number of times; the object being to destroy the men, carriages, and traverses situated upon it. To do this the projectile should be made to graze the crest of the adjacent parapet, and strike the terre-plein as near the foot of the interior slope as possible; the distance of the crest, and its height above the terre-plein and battery, should therefore be known.

Rolling fire is a particular case of ricochet-fire, produced by placing the axis of the piece parallel, or neary so, with the ground. It is generally used in field service. When the ground is favorable for ricochet, the projectile, in rolling fire, has a very long range, and never passes at a greater distance above the ground than the muzzle of the piece; it is therefore more effective than direct fire, as may be seen by inspecting Fig. 3. To point a piece in rolling fire, direct it at the object, and depress the natural line of sight so as to pierce the surface of the ground about 80 yards in front of the muzzle; if the piece be sighted for the pendulum hausse, aim directly at the object with the lowest line of sight, or with the slider fixed at the zero-point of the scale. A fire is said to be *plunging* when the object is situated below the piece. This fire is particularly effective against the decks of vessels.

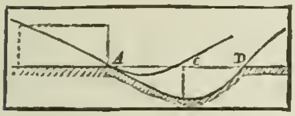


Fig. 1.

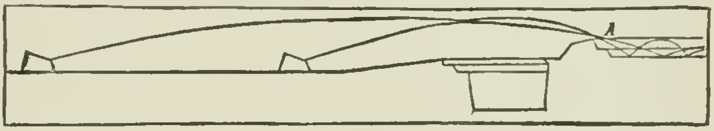

Fig. 2.

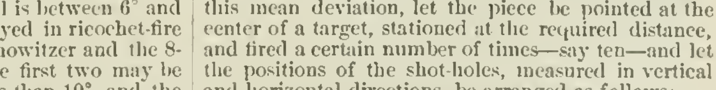

Fig. 3.

Before proceeding to describe the fires of different kinds of projectiles, it may be proper to explain what is meant by accuracy of fire, and to determine a suitable measure for it. It has been seen that there are causes constantly at work to deviate nearly every projectile from its true path. As the effect of these deviating forces cannot be accurately foretold, there is only a probability that the projectile will strike the object against which the piece is pointed. The degree of probability is called accuracy of fire. For all projectiles of the same nature, the chance of hitting an object increases with the velocity and weight of the projectile, whereby the effects of the deviating forces are diminished; it also increases as the size of the object is equal to, or greater than, the mean deviations, and as the trajectory more nearly coincides with the line of sight. If the size of the object be greater than the extreme deviation, and the trajectory coincide with the line of sight, the projectile will be certain to hit the object at all distances. For the same trajectory, therefore, the mean deviation of a projectile at a given distance may be taken as an indirect measure of its accuracy at this distance. To obtain this mean deviation, let the piece be pointed at the center of a target, stationed at the required distance, and fired a certain number of times—say ten—and let the positions of the shot-holes, measured in vertical and horizontal directions, be arranged as follows:

No. of Shot	Distances from Center of Target, in Feet.				Distances from Center of Impact, in Feet.			
	Vertical.		Horizontal.		Vertical.		Horizontal.	
	Above.	Below.	Right.	Left.	Above.	Below.	Right.	Left.
1	3		4		4.33		2.66	
2		6		2		4.66		3.33
3		1	2		.33		.66	
	3	7	6	2	4.66	4.66	3.33	3.33
	4 + 3 = 1 33		4 + 3 = 1.33		9.32 + 3 = 3.11		6.66+3=2.22	

The algebraic sum of the distances in each direction, divided by the number of shots, gives the position of the center of impact in this direction. In the above table the position of the center of impact is found to be 1.33 feet below, and 1.33 feet to the right, of the center of the target. To obtain the mean deviation, it is necessary to refer each shot-hole to the center of impact as a new origin of co-ordinates; and this is done by subtracting the tabular distance from the distance of the center of impact if both be on the same side of the center of the target, and adding them if on different sides. The sum of all the distances thus obtained in one direction, divided by the number of shots, gives the mean deviation in that direction; which in the present case is 3.11 feet vertically and 2.22 horizontally. The vertical deviation of a projectile is generally greater than its corresponding horizontal deviation, and this difference increases with the range. As objects against which military projectiles are directed present a greater extent of surface in a horizontal than in a vertical direction, it becomes necessary to exercise great care in the selection of the proper angle of fire. If the ground or water in front of the object be favorable to ricochet, the difficulty will be diminished by aiming so that the projectile will strike the object after one or more rebounds.

Solid shot are generally used for percussion and penetration, and, when heated to a red heat, for the purpose of setting fire to wooden vessels or buildings. From their great strength, they can be fired with a large charge of powder, which gives them great initial velocity, and having great density, which diminishes the effect of the resistance of the air, they have great range and accuracy. In firing hot shot, the charge should be reduced, to prevent too great penetration, which would exclude the air and render combustion impossible. The extreme range of field-artillery is about 3000 yards; it is not very effective, however, beyond 1700 yards for the 6-pounder and 2100 yards for the 12-pounder. At 600 yards the horizontal deviation of the 12-pounder is about 3 feet, and at 1200 yards it is about 12 feet. For the 6-pounder the deviations are somewhat greater at both distances. The service of solid shot demands less skill than that of shells and spherical case-shot, and they are often effective when the latter are rendered non-effective by untimely explosion.

The diameter and velocity of two projectiles being the same, the retarding effect of the air is inversely proportional to their weight; hence we see that a shell has less accuracy and range than a solid shot of the same size, in the proportion of 3 to 2—these numbers representing the weights of a solid shot and shell respectively. As shells act both by percussion and explosion, they are particularly effective against animate objects, earthworks, buildings, block-houses and shipping, posts and villages occupied by troops, and against troops sheltered by accidents of the ground; but against good masonry they have but little effect, as they break on striking. Against troops, especially cavalry, they possess a certain moral effect which solid shot do not possess. They are used to form breaches in intrenchments, in which case they act as small mines. The 32-pounder shell is the most effective field-projectile for this purpose; and, when fired with a large charge, has a penetration of from 5 to 8 feet in fresh earth.

The extreme range of field-shells is from 2500 to 3000 yards. The 24-and 32-pounder shells burst into about eighteen effective fragments, some of which are thrown to a distance of 600 yards. All field-shells have considerable lateral deviation; it is stated that the 24-pounder shell is sometimes deviated as much as 30 yards in 1200. The extreme range of the mountain-howitzer is about 1200 yards, after three or four rebounds. The 12-pounder shell employed in this service bursts into twelve or fifteen fragments, some of which are thrown to a distance of 300 yards. The great weight of an 8-inch shell, and the large quantity of powder which it contains, render it a very formidable projectile against the traverses and epaulements of siege-works. In sea-coast defense, the 8-, 10-, and 15-inch shells are very destructive to vessels built of timber. They range from 3 to 3½ miles; but the angle which the trajectory makes with the line of sight at this distance (about 40°) renders their fire very uncertain against individual objects of the size of a ship: but it is presumed that they would have the effect to prevent a blockading fleet from lying at anchor within their range, as it is well known that a single 10-inch shell, striking on the deck of a vessel, has sufficient force to penetrate to the bottom and sink her. The 8-inch shell bursts into 28 or 30 fragments; and from the experiments made at Brest, some years ago, it was inferred that three or four of these shells, properly timed and directed, were capable of disabling a ship of war.

Mortar-shells are employed to break through the roofs of magazines, etc., and to blow them up; to destroy the surface of the terre-pleins, ditches, etc., by forming deep hollows, which are produced by explosion, and to interrupt the communications from one part of a work to another. The great depth to which mortar-shells penetrate in earth almost entirely destroys the effect of their fragments; some remain buried in the ground, and the others are thrown out at too high an angle to be dangerous. One of the principal objects of traverses, on a terre-plein, is to confine the bursting-effects of shells within narrow limits. Mortar-shells penetrate from half a yard to one yard in earth; and the amount of earth thrown up by explosion is about one cubic yard for each pound of the bursting-charge. Ordinarily the diameter of the crater at the top is two or three times the depth. The 13-inch shell will often break in falling on a pavement. Roofs of good masonry, little more than a yard thick, are sufficient to resist the penetration of mortar-shells. The effect of mortar-firing is generally in favor of the besiegers, as the works of the besieged present a larger and more favorable surface for the action of shells. The charge of a stone mortar should be small, to prevent the stones and grenades from being too much scattered. A charge of stones is generally scattered over a space varying from 30 to 50 yards broad, and from 60 to 100 yards long. The dispersion of grenades is somewhat less than this; the larger portion, however, are found within a radius of 12 or 15 yards.

When a shrapnel or case-shot bursts in its flight, the fragments of the case and the contained projectiles are influenced by two forces, viz., the force of propulsion, which moves each piece in the direction of the trajectory, and the force of rupture, which moves it in the direction of a normal to the surface of the case. The path described by each fragment and projectile depends on the angle which the normal makes with the trajectory, and on the relative velocities generated by the two forces; and, when taken together, these paths form a species of cone, called the

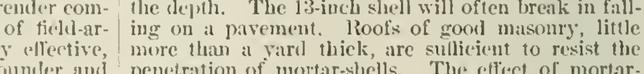

FIG. 4.

cone of dispersion, the apex of which coincides with the point of rupture, and the axis is the trajectory, prolonged. (Fig. 4.) The velocity of a projectile diminishes from the time it leaves its piece, while the velocity generated by the rupturing force remains constant. It follows, therefore, that the dispersion of a spherical case-shot increases with the distance, while the force of impact is diminished. The distance at which a spherical case-shot ceases to be effective depends on the relation between the remaining velocity and the velocity generated by the force of rupture. The improvements which have lately been introduced into this species of projectile have for their objects to increase the remaining velocity at any point by increasing the propelling charge, and to diminish the force of rupture, and at the same time increase the number of contained projectiles, by diminishing the bursting-charge. By filling the interstices of the bullets with sulphur or rosin, the propelling charge of a spherical case-shot can be made the same as that of a solid shot.

It is considered that a spherical case-shot is effective when a large portion of the projectiles have sufficient force to penetrate 1 inch of soft pine. The present 12-pounder spherical case-shot, fired with a charge of 2½ pounds of powder, has a remaining velocity of about 500 feet at a distance of 1500 yards, which renders it effective at this distance. The principal difficulty experienced in firing a spherical case-shot is to burst it at the proper distance in front of the object. This arises from the difficulty of estimating the correct distance of the object, the rapid flight of the projectile, and the difficulty of observing the effect of a shot in order that correction may be made for the succeeding one if necessary. To overcome these difficulties requires skill and judgment on the part of the gunner, and great accuracy and delicacy in the operation of the fuse. The proper position of the point of rupture varies from 50 to 130 yards in front of, and from 15 to 20 feet above, the object. The weight of a spherical case-shot is about the same as a solid shot of the same size, and, being fired with the same charge of powder, it can be used for attaining long ranges in the absence of solid shot. For this purpose the fuse should not be cut. Spherical case-shot should not be used for a less distance than 500 yards; although in cases of emergency the fuse may be cut so short that the projectile will burst at the muzzle of the piece, in which case it will act like grape or canister shot.

In grape and canister firing, the apex of the cone of dispersion is situated in the muzzle of the piece, and the destructive effect is confined to short distances. The shape of this cone is the same as in spherical case-shot; its intersection by a vertical plane is circular, while that of a horizontal plane, as the ground, is an oval, with its greatest diameter in the plane of fire. The greatest number of projectiles are found around the axis of the cone, while the extreme deviations amount to nearly one tenth of the range. The most suitable distance for field canister-shot is from 350 to 500 yards; if the ground be hard and the surface be uniform, the effect may extend as far as 800 yards. In cases of great emergency a double charge of canister, fired with a single cartridge, may be used for distances between 150 and 200 yards. Under favorable circumstances, one third of the whole number of contained projectiles will strike the size of a half-battalion front of infantry, and one half the front of a squadron of cavalry. Grape and canister shot are employed in siege and sea-coast operations; in the latter they are effective against boats and the rigging, etc., of vessels. Grape-shot, being larger than canister-shot, are effective at greater distances. Canister-shot for the mountain-service are not effective beyond 250 and 300 yards.

Beyond 200 yards the fire of the smooth-bored musket becomes very uncertain against individual objects, as the lateral deviations often exceed four feet; but by aiming high it may be made effective against troops in mass at 400 yards. The fire of the rifle-musket is effective at 1000 yards; the angle of fall, however, is so great (about 5°) that great care must be exercised in determining the exact distance of the object. If the ground be favorable, the projectile will ricochet at 1000 yards, which increases the *dangerous space*, and therefore the chances of hitting the object. The limit of any fire is determined by the distinctness of vision. The limit of distinct vision for a foot-soldier is about 1100 yards; that for a mounted soldier is about 1300 yards. The effect of small-arm firing depends much on the skill and self-possession of the soldier in action, for without these qualities the most powerful and accurate arms will be of little avail. The number of cartridges expended for each person disabled in previous European wars has been variously stated to be from 3000 to 10,000. In the late Mexican war, where an unusually large proportion of the American troops were armed with rifles, this number has been estimated to be from 300 to 400. Where a soldier discharges his piece from the back of a horse, as in the cavalry service, the effect of fire is much less than in the dragoon and mounted-rifle services, where he rides from point to point, but discharges his piece on foot. At short distances, and against troops in mass, two or three round bullets may be employed with good effect. See *Cannon*, *Firing* and *Pointing*.

2. Whether a tribe of men ignorant of fire and its uses has ever existed, is a question in dispute among historians and travelers. It will be enough to say that absolute proof of the existence of such a tribe has not been presented, though there are many well-authenticated facts and circumstances that suggest its possibility. The uses and dangers of fire, and to a certain extent the means of controlling it, must have been generally understood at a very early age. At first it may have been simply an object of terror, but probably men soon discovered that it was a friend no less than an enemy. Concussion or friction was undoubtedly the earliest method employed for producing fire. In the process of chipping stone, sparks were elicited, which, falling upon combustible substances, may have taught men how to produce a blaze at pleasure. The concussion of flint and steel was for ages doubtless the common method of kindling a fire, and it has not yet been entirely superseded. The Alaskans strike together two pieces of quartz, rubbed with sulphur, thereby setting the sulphur on fire, and then transfer the flame to a heap of dry grass. The Esquimaux use quartz and iron pyrites. In some countries sparks are produced by striking a piece of broken china upon bamboo; in Cochin China two pieces of bamboo are used, the silicious character of the outside layer of this wood rendering it as good as native flint. Numerous mechanical devices for increasing by rapidity of motion the friction of different woods were resorted to. In some cases a stick was rubbed backward and forward; in others it was made to rotate rapidly in a round hole in a stationary piece of wood. This method was used by the North American Indians, who improved it by applying the principle of the bow-drill. The Iroquois used the still more ingenious pump-drill. The production of fire by concentrating the rays of the sun by means of a burning-glass was well known to the ancients. North American legends narrate how the great buffalo, careering through the plains, makes sparks flit in the night, and sets the prairie ablaze by his hoofs hitting the rocks. The same idea appears in the Hindu mythology. To save the labor required in these initial processes of procuring light, and to avoid the inconvenience of carrying it about continually, primitive men hit on the expedient of a fire which should burn night and day in a public building. The Egyptians had one in every temple, the Greeks, Latins, and Persians in all towns and villages. Of these the "eternal lamps" in the Byzantine and Catholic churches may be the survival. Even the functions of the State itself, according to some eminent writers, appear to have grown out of the care bestowed on the tribal fire. The first guardians of this fire, it is said, were the earliest public servants, who by degrees appropriated all important offices, as the State itself developed into a vast aggregation of interests. The men who in the Roman Empire took charge of the tribal fire were called the Prytanes. They were fed at the public expense, and they became Magistrates, in whom were combined the powers of Captain, Priest, and King. When Augustus usurped the authority of Imperator, he assumed the powers which belonged to a Board of Flamens, or of Prytanes. He made himself Pontifex Maximus, and assumed the charge of the public fire. The

Hellenic nations, as well as the Aztecs, received their Ambassadors in their temples of fire, where, as at the national hearth, they feasted the foreign guests. The Prytaneion and the State were convertible terms. If by chance the fire in the Roman Temple of Vesta was extinguished, all tribunals, all public or private business, had to stop immediately. No Greek or Roman army crossed the frontier without carrying an altar where the fire taken from the Prytaneion burned night and day. Greek Colonies went not forth without living coals from the altar of Hestia, to light in their new country a fire like that burning at the old home. Architecture, it is supposed, began with the creation of sacred sheds to protect the sacred fire, which was looked upon as a divinity. The fire that burned in the Temple of Vesta was regarded as the very goddess herself. The hearth-fire was kept holy, its flame was to remain bright and pure. According to the Zend Avesta nothing unclean was to be thrown into the fire, and no indecent actions were to be committed before it. To spit in one's fire would be considered in some places an unpardonable offense. Some people were so reverent that they would not blow out a light lest they should render the flame impure with their breath. In the course of time the same reasons which led to the provision for a tribal fire induced every family to have its hearth. The family developed itself only after the married pair and their offspring had their own fireplace. This family fire was at first the privilege of only the aristocracy. The hearth was the very center of the house, as the regia was the sacred center of Rome and the Roman Commonwealth; around the regia the civic and politic institutions developed themselves; and around the hearth the family grew slowly into shape and power. Let us hope it may not decline under the influence of those "modern improvements" which have superseded the hearth-stone and banished from sight the household fire. The Gentile hearth gave a recognized asylum—a right still in full vigor in some countries. The proud saying of the Englishman that his home is his castle is a remnant of this old feeling.

3. In armorial bearings the fire is used to denote those who, being ambitious of honor, perform brave actions with an ardent courage, their thoughts always aspiring as the fire tends upwards. A flame of fire is more frequently used as a charge in France and Germany than in England, where, however, there are fire-balls or bombs, fire-beacons, firebrands, and fire-buckets, etc., in abundance.

FIRE-ALARM.—An alarm given of a fire or conflagration. In barracks or camp it is sounded on the drum or bugle, or by the discharge of fire-arms by the guard. As soon as the fire is observed, the sentinel on post cries "Fire!" adding the number of his post. If the danger appears great, he discharges his piece before calling out. When a fire breaks out, or any alarm is raised in a garrison, all guards are immediately under arms.

FIRE AND SWORD.—By the law of Scotland, although decree may be given in a civil action against an absent defender, no criminal sentence can be pronounced unless the accused be present. But to resist a criminal citation is to rebel against the law of the land, and in former times might be treated as treason. In this view, letters of *fire and sword* were occasionally issued by the Privy Council. These letters were directed to the Sheriff of the county, authorizing him to call in the assistance of the country, and to proceed to the extremities which the terrible words fire and sword indicate, should such proceedings be necessary for apprehending the accused party. Lord Stair describes this remedy as the "last legal execution, warranting all manner of force of arms that is competent in war." The same course might be resorted to where the decree of a Court was resisted; and the object with which letters of fire and sword were more frequently issued than any other was to enable the Sheriff to dislodge refractory tenants who retained possession contrary to the order of the Judge or the diligence of the law. By the modern practice the Judge may, of course, always call in the aid of the military to apprehend an accused party, or to enforce a decree where the ordinary means have proved unavailing.

FIRE-ARMS.—Fire-arms may be defined as vessels, of whatever form, used in the propulsion of shot, shell, or bullets to a greater or less distance by the action of gunpowder exploded within them. They have played so great a part in the world's story that their invention, development, and science deserve careful analysis. At a more advanced period, an obvious division of the subject into cannon, mortars, and small-arms presents itself; but in the infancy of the invention, and amid the obscurity enshrouding it, we can only seek to inquire into the origin of fire-arms generally. The invention of gunpowder bears so directly upon the gradual introduction of fire-arms that it will be well to consider the two discoveries concurrently. The widely prevalent notion that gunpowder was the *invention* of Friar Bacon, and that cannon were first used by Edward III. of England, must be at once discarded. It is certain that gunpowder differed in no conspicuous degree from the *Greek fire* of the Byzantine Emperors, nor from the *terrestrial thunder* of China and India, where it had been known for many centuries before the chivalry of Europe began to fall beneath its leveling power. "Niter," says Sir George Staunton, "is the natural and daily produce of China and India; and there, accordingly, the knowledge of gunpowder seems to be coeval with that of the most distant historic events." The earlier Arab historians call saltpeter "Chinese snow" and "Chinese salt;" and the most ancient records of China itself show that, when they were written, fire-works were well known several hundred years before the Christian era. From these and other circumstances, it is indubitable that gunpowder was used by the Chinese as an explosive compound in prehistoric times; when they first discovered or applied its power as a propellant is less easily determined. There is an account of a bamboo tube being used, from which the "impetuous dart" was hurled a distance of 100 feet; this was at a very early period, but it is difficult to say precisely when. It is recorded, however, that in 618 B.C., during the Taing-off dynasty, a cannon was employed bearing the inscription: "I hurl death to the traitor, and extermination to the rebel." This must almost necessarily have been of metal. We have also curious evidence in regard to the armament of the great wall; for Captain Parish, who accompanied Lord Macartney's mission, reported that "the soles of the embrasures were pierced with small holes, similar to those used in Europe for the reception of the swivels of wall-pieces. The holes appear to be part of the original construction of the wall, and it seems difficult to assign to them any other purpose than that of resistance to the recoil of fire-arms." If this surmise be correct, the use of jingalls would be carried back to three centuries at least before the Christian era. Stone mortars, throwing missiles of 12 lbs. to a distance of 300 paces, are particularly mentioned as having been employed in 757 A.D. by Thang's army; and in 1232 A.D. it is incontestable that the Chinese besieged in Caïfong-fou used cannon against their Mongol enemies. Thus, the Chinese must be allowed to have established their claim to an early practical knowledge of gunpowder and its effects.

It seems likely, however, that the principles of fire-arms reached Europe from India rather than China, and that country has equal, if not superior, claims to the first acquaintance with the art. The ancient Sanscrit writings appear to point very plainly to the operation of some primitive sort of cannon, when, in recording the wars of the Egyptian Hercules in India, it is stated that the sages remained unconcerned as spectators of the attack on their stronghold, till an assault was attempted, when they repulsed it with whirlwinds and thunders, hurling destruction on the invaders; and a Greek historian of Alexander's campaign testifies that the Hindus had the means of discharging flames and missiles on their enemies from a distance. These Indian philosophers seem, from the writings of Ctesias and Ælian, to have also possessed an unquenchable fire similar to that employed later by the Greeks. Passing from these very early times, in which there is reason to believe that some sort of great-gun was employed, we come to the comparatively recent date, 1200 A.D., when their use is established beyond a doubt, for Chaséd, the Hindu bard, writes (in stanza 257) that the culivers and cannons made a loud report when they were fired off, and that the noise of the ball was heard at the distance of about ten coss, which is more than three quarters of a mile. In 1258 the vizier of the King of Delhi went forth to meet the Ambassador of Hulaku, the grandson of Genghis Khan, with 3000 carriages of fire-works (in the sense of weapons, probably a sort of rude muskets). In 1368, 300 gun-carriages were captured by Muhammed Shah Bahmiani. The use of cannon had so far advanced in India by 1482 that they were even used for naval purposes; shells having been employed two years earlier by the Sovereign of Guzerat. In 1500 the Portuguese had matchlockmen to contend with, as well as heavy ordnance. Pigafetta, in 1511, found the town of Borneo defended by 62 pieces of cannon mounted on the walls. So much for the antiquity and apparently common use of fire-arms in China and India, at times long antecedent to any knowledge of them in Europe, and during the period at which they were scarcely developed in an effectual degree. Most of the pieces discovered in India, and supposed to be of early manufacture, are composed of parallel iron bars welded together, and very often they had a movable breech-piece. The knowledge of gunpowder and fire-arms may be presumed to have extended in a westerly direction through the Arabs, whom we find using them possibly in 711 A.D., under the name of *manjaniks*, and certainly very early in the fourteenth century. The Byzantine Emperor Leo introduced "fire-tubes" between 890 and 911, for use in connection with Greek fire; and there can be little doubt that these were a species of cannon, probably of small bore. In Spain, both the Moors and Christians used artillery as early as the twelfth century.

Friar Bacon was conspicuous among his contemporaries for his general learning, and we have no evidence to show whether he discovered the ingredients of gunpowder independently of all foreign aid, or whether he derived the knowledge from some ancient MSS.; the latter, however, seems the more likely conclusion, as Sir F. Palgrave brought to light in the Bodleian Library a letter from a Spanish friar, Brother Ferrarius, who was a contemporary of Bacon, in which the materials of Greek fire are detailed, differing only in proportions, and in these but slightly, from real gunpowder. That the latter was identified of old with Greek fire is shown by the name "Crake," applied to the first cannon used. This word, which still survives in "cracker," is pointed out by Sir F. Palgrave to be nothing more than a Norman corruption of "Grec." Bacon's announcement dates from 1216; but the powder of his time, as made in the West, was not readily explosive, since the materials were but roughly cleared of impurities, and then mixed together on a slab, and probably little use could be made of it as a propellant until the process of granulating had been introduced by Bertholdus Schwartz in 1320. Immediately after this discovery, cannon of small size appeared in the armory of almost every State, as if their use had been known previously, although no practical effect had been given to the knowledge, on account of the badness of the powder manufactured. These cannon generally consisted of a smaller barrel or chamber to receive the charge, which fitted into a larger one containing the projectile. It may be safely assumed that these weapons, if terrifying from their noise, were tolerably harmless—at least to the enemy—in their practice. In 1326 the Florentine Republic ordered the making of iron shot and cannon for the defense of its villages. In 1327 Edward III. used "crakeys of war" against the Scotch; in 1339, ten cannons were employed in the siege of Cambray. By 1346, various improvements had been made; and we find in the same year the Consuls of Bruges witnessing experiments by one Peter, a tinman, who had constructed a cannon with a square bore, to throw a cubical shot of about 11 lbs.; his bolt passed both walls of the town, and unfortunately killed a man on the other side. We have the authority of Villani for believing that Edward III. had three cannon at Crécy; but the cannon then made were, from the little knowledge of casting, limited to about the size of modern duck-guns, and, as has been remarked, three very inferior muskets could have had but little to do with putting 50,000 men to flight. Up to this time European ordnance had been kept back by the rarity and high prices of sulphur, saltpeter, and iron, the last having been so scarce in England that it was thought necessary to forbid its exportation by a statute. Still, crude as was their form, and small their number, fire-arms had established a firm footing in Christendom: their mission of civilization, and, paradoxical as it may appear, of humanity, had begun. With the first killing discharge, the doom of feudalism had gone forth. Plated armor no longer availed against the weapon of the peasant; and the mailed chivalry, the sinews of previous battles, who had trampled with their iron heels upon popular rights, no longer could carry all before them, but, like other soldiers, were now as loath to be slain by unseen foes as the veriest villain in the host. The people discovered their powers of contending with the noblesse; by degrees they rose for liberty and suppressed the tyrannies of the petty lords who had long held them as mere bondsmen. In war, again, as artillery became more general, so the slaughter of battles diminished, for an army outmaneuvered was an army at the enemy's mercy, and therefore beaten; whereas previously, in the hand-to-hand fights where victors and vanquished mixed pell-mell in single combat, a victory could only be really won when there were no foes left to slay. A battle as great as that at Crécy might now be gained with a loss to the vanquished of not more than 1000 men, instead of the 30,000 who are said to have fallen victims to the English sword or bow.

Dating from the reign of Edward III., the employment of cannon and bombards in siege-operations became more or less general. Froissart records that the Black Prince took bombards, cannon, and Greek fire to the reduction of the castle of Romozantin in 1356, but it does not appear that he availed himself of fire-arms at the battle of Poitiers in the same year. The bombards seem to have been short, capacious vessels, from which stone balls were shot with small charges to a short distance, and at considerable elevation; they were essentially the parents of the present bombs or mortars. The cannon, on the other hand, were, for some time at least, of extremely small bore, scarcely larger than muskets of the eighteenth century; they discharged leaden bullets, and would have probably been used as hand-weapons but for their cumbrous and heavy workmanship, which necessitated small carriages. Arms of this description are doubtless those referred to as having been brought by Richard II. to the siege of St. Malo, to the number of 400 pieces, where they are said to have kept up an incessant fire day and night on the town *without* success. In the fifteenth century, armies for siege-operations were usually accompanied by great and small guns, the latter being intended to keep down the fire of the besieged while the large bombards were being loaded, an operation requiring no small time. These guns were gradually improved, but it was not until the reign of Henry VIII. that the founders succeeded in casting iron ordnance, to the entire exclusion, until quite the present day, of cannon formed of square or rounded bars welded together. England had even then become famous for the workmanship of its ordnance. A gun found in the wreck of the *Mary Rose*, which sunk at Spithead in the above king's reign, shows that a degree of excellence had been attained in the manufacture of artillery little inferior to that which has lasted till our own day, when rifled ordnance are rapidly superseding cannon of smooth bores. Still, so late as Henry's reign, although great-guns were found very serviceable in siege and naval operations, where the defenses of those days offered but a trifling resistance to their power, they appear to have been looked upon rather as an incumbrance than an advantage with armies in the field. This is attributed partly to the heavy character of the guns themselves, and especially of their carriages, but more particularly to the badness, or rather absence, of the necessary roads for their transport. In 1552 it is recorded in the State-papers that the "kinges ordonauns [were] unable to pass over Stanes More towards Carlile." As time passed on, the details of the manufacture were improved, the general principles remaining the same; the size of the guns increased, while the proportionate weight of the carriages diminished; limbers were added, and the equipage of a gun gradually perfected and lightened. With increased caliber, to which augmented range was usually added, the number of cannon—at one period enormous—taken with an army was by degrees reduced, until now a certain standard proportion between artillery and infantry is ordinarily maintained. Three guns to a thousand infantry is the proportion now considered best. Of course this proportion differs with the opinions of various Commanders; but the greatest modern Generals have always acted on the maxim that it is wasteful to send a soldier on any duty of danger which a ball can be made to perform. As a weapon of offense, Vauban doubled the utility of heavy ordnance when he applied the ricochet system of firing. Napoleon may almost be said to have won his battles by artillery, for he rarely, if ever, brought his infantry into action except as supports, until a way had been opened for them, or a panic caused, by the massed fire of large batteries of guns. The Duke of Wellington also devoted the greatest attention to his ordnance-train; while, referring to recent events, the campaigns of Lord Clyde in India were remarkable instances of the use of artillery being pushed with abundant success to its greatest limit. During the Franco German War of 1870–71 the Prussians were considered somewhat behind the age in their use of artillery.

Cannon of widely varying bores have at different periods been cast, and the various sorts became so numerous in Continental armies as at one time to cause much inconvenience from the large quantities of ammunition which it was necessary to carry. Gustavus Adolphus set the example of reducing his guns to a few standard calibers, and the same improvement was immediately adopted systematically in the French and other armies. The mortar differs from all other guns in its solidity of form, its shortness, and its large bore. The object is the projection of shells by a more or less vertical fire, with the intention of breaking through and destroying, by weight and explosion together, roofs of magazines, public buildings, and so on, or of sinking a shell deep into earthworks of a fortress, in which it shall explode as a most deadly mine. The mortar arose naturally out of the old bombard, and doubtless deviated by degrees more and more from the cannon. In very early days, we read in Arabian authors of a cylinder hewn in the rock at Alexandria, and used as a mortar. Such a cylinder, and of large size, is still to be seen at Gibraltar, where it was employed in the last siege against the Spanish, when it was made to discharge volleys of large stones, which, spreading at times to a distance of 500 yards, constituted a formidable means of defense. In recent years nearly all guns fire shells, so that the specific necessity for mortars has greatly diminished. A gun is a frustum of a right cone, with a cylinder (bore) removed around the axis; from which it follows that the thickness of metal is greatest at the breech, where it has to withstand the effect of ignited powder in its most condensed and therefore most powerful state. Guns are first cast in loam or dry sand, then turned to the required shape, and lastly bored with the minutest accuracy. Formerly they were cast with the bore already formed; but the direction was rarely correct, and the surface scarcely ever strictly even.

An article on fire-arms would be incomplete without some allusion to the progress attained in small-arms. In the fifteenth century the smallest sort of cannon were probably at times mounted and used as hand-guns. From this the step to the arquebus was rapid; that weapon developed as years passed into the clumsy matchlock; that into the firelock and flint-musket; then the percussion-musket; and lastly into the beautiful rifles of our own day, which have culminated in the central-fire breech-loaders. For diminutives, small arquebuses were made to do duty as horse-pistols; genuine pistols succeeded them; these were gradually improved and reduced in size till they have culminated in the saloon-pistol, available for a waist-coat pocket, and the deadly revolver, with its multiplied shooting power. All these weapons are described under their respective heads. See *Cannon*, *Ordnance*, and *Small-arms*.

FIRE-ARROW.—An arrow or dart furnished with a match impregnated with powder and sulphur, and used for incendiary purposes.

FIRE-BALL.—Fire-balls are projectiles of an oval shape, formed of sacks of canvas filled with combustible composition. They are used to light up the enemy's works, and are loaded with shells to prevent them from being approached. The materials needed in their manufacture are strong, close canvas (sail-cloth); rope; cartridge-thread; red chalk; slow-match; loaded shells; and pitch. A composition of 8 parts of saltpeter, as it comes from the refinery; 2 of pulverized sulphur, and 1 of antimony are passed through sieve No. 2. These materials are mixed in the hands, passed through sieve No. 4, moistened with $\frac{1}{30}$ their weight of water, and passed again through the same sieve. The following utensils are required besides those necessary for grinding and preparing the composition: a wooden pattern; red chalk; one pair shears; collar-needles; mallet; small gauge, of the caliber of the fire-balls; scoop; tarred links; one wooden mold; two wooden drifts 20 inches long, one of them 1½ inch and the other 2½ to 4 inches in diameter; and two wooden pins 4½ inches long, the small end the size of a paper fuse.

To make the sack, mark out the pieces by means of the pattern, and cut them with the shears; baste two or three thicknesses together, according to the strength of the canvas; sew three or more together, enough to make the sack; leave one end open, forming a mouth for charging; turn the bag to bring the seams on the inside. The mouth may be made fast to an iron hoop, large enough to admit the shell, with which the fire-ball is loaded. Charge the shell with powder and put in a slow fuse. Dip the tarred link into the melted rosin, pitch, and tallow, and fasten it with twine to the shell around the fuse-hole. Place the sack in the mold and secure the mouth to it. Put the shell with the tarred link in the bottom of the sack, the fuse-hole downward, and fasten the shell down with twine passed through the sides of the sack, or with a piece of canvas secured to the sides; put in the composition with a scoop and ram it, first with the small drift, and when it is half the height of the projectile, with the large drift, driving it with the mallet. Continue in this way until the sack is filled to the top. Close the mouth of the sack, sewing the pieces together.

The ball is furnished with an iron bottom to prevent it from being broken by the force of the charge in the mortar. To make the bottom, the iron, .2

inch thick, is cut in a circular form, heated and partly shaped with a set-hammer in a concave wooden former; it is again heated and finished in an iron former. It is then put into a lathe where the outer edge is trimmed and chamfered to the thickness of one-eighth inch. The iron bottom is attached to the ball with cement; the bottom is filled about one third full with the cement, and the loaded end of the fire-ball is inserted in it and left to cool. The ball is next covered and strengthened with a network made of spun yarn or cord from .25 to .5 inch thick according to the size of the ball. This network is commenced at the bottom of the sack and terminates at the top in a strong loop which forms a handle for carrying the ball. Fire-balls are dipped in a composition of equal parts of pitch and rosin made warm. The ball when finished should pass through the large shell-gauge.

To prime the balls, make four holes about 3 inches below the top by driving in the greased wooden pins 2 inches deep. When the ball is to be primed, take out these pins and fill the holes with fuses and with two strands of quick match, held fast by the composition; leave room in the priming-hole for coiling the quick-match and cover it with a piece of canvas fastened with four nails. The balls are not primed until they are to be fired. See *Fire-works.*

FIRE-BAVIN.—A bundle of brushwood employed in fire-ships, and for other incendiary purposes.

FIREBRAND MINE.—A variety of mine that preceded the *powder-mine* in the Middle Ages.

FIRE-BUCKET.—A bucket to convey water for extinguishing fires. To each set of quarters in a Garrison there are allotted a certain number of fire-buckets.

FIRE-CROSS.—An ancient token used in Scotland for the nation to take up arms.

FIRE-EATER.—A name applied to a soldier who is notoriously fond of being in action.

FIRE-HOOPS. — A combustible invented by the Knights of Malta to throw among their besiegers, and afterwards used in boarding Turkish galleys.

FIRELOCK.—The name applied on its introduction, in 1690, to the old musket, which produced fire by the concussion of flint and steel, to distinguish it from the *matchlock* previously in use, which had been fired by the insertion of a lighted match at the powder-pan. Writers of the earliest part of the eighteenth century called firelocks "asnaphans," a word obviously corrupted from the Dutch *snaphaan*, and leading to the inference that they were brought to England by William III. and his Dutch auxiliaries. Their first invention is, however, involved in obscurity. The weapon was superseded before 1830 by the percussion-musket; which, in its turn, has now yielded to the rifle. See *Matchlock.*

FIRE-MASTER.—In the artillery, a Commissioned Officer who formerly gave the directions and proportions of all ingredients for each composition required in fire-works, whether for the service of war or for rejoicings and recreation.

FIRE-MASTER'S MATE.—In the artillery, a Commissioned Officer whose duty it was to aid and assist the Chief Fire-master; he was required to be skilled in every kind of laboratory works.

FIRE OF GREATEST RANGE.—The fire obtained by giving the piece the greatest elevation it can take on its carriage, and employing the largest charge used for that caliber. This kind of fire is very injurious to the carriage, and is employed only in testing.

FIRE-PAN.—A pan for holding or conveying fire; especially, the receptacle for the priming in a gun.

FIRE-SHIP.—A vessel, usually an old one, filled with combustibles, sent in among a hostile squadron, and there fired, in the hope of destroying some of the ships, or at least of producing great confusion. Livy mentions the use of such by the Rhodians, B.C. 190; but among the first occasions in modern times when they are known to have been employed were by the Dutch in the Scheldt during the War of Independence in the Netherlands, and shortly after by the English, in 1588, against the Spanish Armada. The Chinese tried them against the British fleet before Canton in 1857, but unsuccessfully. The service of navigating one of these ships into the midst of an enemy, there firing it, and then attempting to escape, is always fraught with great risk of failure and disaster.

FIRE-STEEL.—A steel used in connection with a flint for striking fire. Now little used.

FIRE-STONE.—A composition placed in a shell with the bursting charge to set fire to ships, buildings, etc. It is made by stirring niter, sulphur, antimony, and rosin in a mixture of melted tallow and turpentine. It is cast in molds made of rocket-paper. A priming of fuse-composition is driven in a hole to insure its ignition.

FIRE-SWAB.—The bunch of rope-yarns sometimes secured to the tampion, saturated with water to cool the gun in action, and to swab up any grains of powder.

FIRE-WORKER.—Formerly an assistant to the Fire-master. In the early organization of the British artillery, this title was given to the junior subaltern grade, the designation of the officer being Lieutenant Fire-worker. See *Fire-master.*

FIRE-WORKS.—Military fire-works comprise preparations for the service of *cannon ammunition*, and for *signal*, *light*, *incendiary*, and *defensive* and *offensive* purposes.

Preparations for the Service of Ammunition.—The preparations for the service of ammunition are *slow-match*, *quick-match*, *port-fires*, *friction-tubes*, and *fuses*. Slow-match is used to preserve fire. It may be made of hemp or cotton rope; if made of hemp, the rope is saturated with acetate of lead, or the lye of wood-ashes; if made of cotton, it is only necessary that the strands be well twisted. Slow-match burns from four to five inches in an hour. Quick-match is made of cotton-yarn (candle-wick) saturated with a composition of mealed powder and gummed spirits; after saturation the yarn is wound on a reel, sprinkled (dredged) with mealed powder, and left to dry. It is used to communicate fire, and burns at the rate of one yard in thirteen seconds. The rate of burning may be much increased by inclosing it in a thin paper tube called a *leader*. Port-fires are paper cases containing a composition, the flame of which is capable of quickly igniting primers, quick-match, etc. The composition consists of niter, sulphur, and mealed powder. A port-fire is about 22 inches long, and burns with an intense flame for ten minutes. Friction-tubes are at present the principal preparations for firing cannon; the advantages are portability and certainty of fire. They also afford the means of firing a piece situated at a distance, and do not attract the notice of the enemy's marksmen at night. They are made of two brass tubes soldered at right angles. The upper or short tube contains a charge of friction-powder and the roughed extremity of a wire loop; the long tube is filled with rifle-powder, and is inserted in the vent of the piece. When the extremity of the loop is violently pulled, by means of a lanyard, through its hole in the long tube, sufficient heat is generated to ignite the friction-powder which surrounds it, and this communicates with the grain-powder in the longer tube. The charge of grained powder has sufficient force to pass through the longest vent and penetrate several thicknesses of cartridge-cloth. The composition of friction-powder is one part of chlorate of potassa and two parts of sulphuret of antimony. Fuses are the means used to ignite the bursting-charge of a hollow projectile at any desired moment of its flight; they may be classified according to their mode of operation, as time-fuses, percussion-fuses, and combination-fuses.

Fire-works for Signals.—Rockets for signals are composed of a paper case charged with composition, a pot filled with ornaments, and a light stick to give direction. Rockets are denominated by the interior diameter of the case. The most common sizes are the .75-inch, 1-inch, and 1.5-inch. The decorations of rockets are stars, serpents, marrons, gold-rain, rain of fire, etc. STARS are formed by driving the composition, moistened with alcohol and gum-arabic in solution, in port-fire molds. It is then cut into lengths about ⅝ inch, and dredged with mealed powder. The case of a SERPENT is similar to that of a rocket, but the interior diameter is only .4 inch. The composition is driven in, and the top is closed with moist plaster of Paris. It is primed by inserting a small piece of quick-match through the vent; it may be made to explode by driving mealed powder over the composition. The composition is 3 parts of niter, 3 parts of sulphur, 16 parts of mealed powder, and ½ part of charcoal. MARRONS are small paper shells, or cubes, filled with grained powder, and primed with a short piece of quick-match, which is inserted in a hole punctured in one of the corners. To increase the resistance of the shell it is wrapped with twine, and dipped in *kit* composition. The stick is a tapering piece of pine about nine times the length of the case, and is tied to the side of the case to guide the rocket in its flight. The position of the center of gravity depends on the diameter of the case; for a 2-inch rocket it should be 2½ inches in rear of the vent; and it is verified by balancing on a knife-edge. The prescribed dimensions of the stick should be observed, for if the stick be too heavy the rocket will not rise to a proper height; if it be too light it will not rise vertically. A very brilliant BLUE-LIGHT may be made of the following ingredients, viz.: 14 parts of niter, 3.7 parts of sulphur, 1 part of realgar, and 1 part of mealed powder. The brilliancy depends on the purity and thorough incorporation of the ingredients. The composition may be driven in a paper case, and afterward cut off to suit the required time of burning. Both ends of the case are closed with paper caps, and primed with quick-match, in order that one or both ends may be lighted at pleasure. A light in which the composition is 1.5 inches diameter can be easily distinguished at the distance of 15 miles.

INCENDIARY FIRE-WORKS.—The incendiary preparations are *fire-stone, carcasses, incendiary-match*, and *hot-shot*. FIRE-STONE is a composition that burns slowly but intensely; it is placed in a shell, along with the bursting charge, for the purpose of setting fire to ships, buildings, etc. It is composed of 10 parts of niter, 4 parts of sulphur, 1 part of antimony, and 3 parts of rosin. The composition having been properly pulverized and mixed is added to melted tallow and turpentine in small quantities. Each portion of the composition should be well stirred with long wooden spatulas to prevent it from taking fire, and each portion should be melted before another is added. When fire-stone is to be used in shells it is cast into cylindrical molds made by rolling rocket-paper around a former, and securing it with glue. A small hole is formed in the composition by placing a paper tube in the center of each mold. When the melted composition has become hard, this hole is filled with a priming of fuse composition, driven as in the case of a fuse. The object of this priming is to insure the ignition of the fire-stone by the flame of the bursting-charge. There are two sizes of molds, the larger for shells above the 8-inch, and the other for the 8-inch and all below it. A CARCASS is a hollow cast iron projectile filled with burning composition, the flame of which issues through four fuse-holes to set fire to combustible objects. The composition is the same as for port-fires, mixed with a small quantity of finely-chopped *tar*, and as much *white turpentine* and *spirits of turpentine* as will give it a compressible consistency. The composition is compactly pressed into the carcass with a drift, so as to fill it entirely. Sticks of wood .5 inch diameter are then inserted into each fuse-hole, with the points touching at the center, so that when withdrawn corresponding holes shall remain in the composition. In each hole thus formed three strands of quick-match are inserted, and held in place by dry port-fire composition, which is pressed around them. About three inches of the quick-match hangs out when the carcass is inserted in the piece; previously to that it is coiled up in the fuse-hole, and closed with a patch of cloth dipped in melted kit. A *common shell* may be loaded as a carcass by placing the bursting-charge on the bottom of the cavity, and covering it with carcass-composition driven in until the shell is nearly full, and then inserting four or five strands of quick-match, secured by driving more composition. This projectile, after burning as a carcass, explodes as a shell. INCENDIARY-MATCH is made by boiling slow-match in a saturated solution of niter, drying it, cutting it into pieces, and plunging it into melted fire-stone. It is principally used in loaded shells. HOT SHOT may be fired for the purpose of setting fire to wooden vessels, buildings, etc. Solid shot are heated in a furnace before firing, to a red heat. The time required to heat a 42-pounder shot to a red heat is about half an hour. The precautions to be observed in loading hot shot are that the cartridge be perfectly tight, so that the powder shall not scatter along the bore, and that a wad of pure clay, or hay soaked in water, be interposed between the cartridge and the shot. When properly loaded the shot may be allowed to cool without igniting the charge. In the British sea-coast service shells are used for incendiary purposes by filling them with molten iron drawn from a small cupola furnace. If the shell be broken on striking, the hot iron is scattered about; if it be not broken, the heat penetrates through the shell with sufficient intensity to set wood on fire.

FIREWORKS FOR LIGHT.—The preparations for producing light are fire-balls, light-balls, tarred links, pitched fascines, and torches. A FIRE-BALL is an oval-shaped canvas sack filled with combustible composition. It is intended to be thrown from a mortar to light up the works of an enemy, and is loaded with a shell to prevent it from being approached and extinguished. The sack is made of sail-cloth, cut into three oval pieces or gores, and sewed together at their edges. Several thicknesses of cloth may be used if necessary. One end of the sack is left open, and, after being sewed, it is turned to bring the seam on the inside. The composition for a fire-ball consists of 8 parts of niter, 2 parts of sulphur, and 1 part of antimony. After having been pulverized, mixed, and sifted, the composition is moistened with one thirtieth of its weight of water, and again passed through a coarse sieve. The ball is filled by pouring a layer of composition into the sack, and placing the shell (fuse down) upon it; after this, the composition is well rammed around and above the shell, and the sack is closed at the top. The bottom of the sack is protected from the force of the charge by an iron cup called a *culot*, and the whole is covered and strengthened with a network of spun-yarn, or wire, and then overlaid with a composition of pitch, rosin, etc. A fire-ball is primed by driving into the top of the composition a greased wooden pin about three inches deep and filling the hole thus formed with fuse-composition, driven as in a fuse; space is left at the top of each hole for two strands of quick-match, which are fastened by driving the composition upon them. The fuse-hole is covered with a patch saturated with kit-composition, which is a mixture of rosin, beeswax, pitch, and tallow. LIGHT-BALLS are made in the same manner as fire-balls, except that, being used to light up our own works, the shell is omitted. TARRED LINKS are used for lighting up a rampart, defile, etc., or for incendiary purposes. They consist of coils of soft rope, placed on top of each other, and loosely tied together; the exterior diameter of the coil is 6 inches, and the interior 3 inches. They are immersed for about ten minutes in a composition of 20 parts of *pitch* and 1 of *tallow*, and then shaped under water; when dry, they are plunged in a composition of equal parts of *pitch* and *rosin*, and rolled in tow or sawdust. To prevent the composition from sticking to the hands, they should be previously covered with linseed-oil. Two links are put into a rampart-grate, separated by shavings. They burn one hour in calm weather, and half an hour in a high wind, and are not extinguished by rain. To light up a defile, the links are placed about 250 feet apart; to light up a march, the men who carry the grates should be placed to the leeward of the column, and about 300 feet apart. Fagots of vine-twigs, or other very combustible wood, about 20 inches long and 4 inches diameter, tied in three places with iron wire, may be treated in the same manner, and used for the same purposes as links. The incendiary properties of PITCHED FASCINES may be increased by dipping the ends in melted rock-fire; when used for this purpose, they are placed in piles intermingled with shavings, quick-match, bits of port-fires, etc., in order that the whole may take fire at once. A TORCH is a ball of rope impregnated with an inflammable composition, and is fastened to the end of a stick, which is carried in the hand. Old rope, or slow-match, well beaten and untwisted, is boiled in a solution of equal parts of water and niter; after it is dry, tie three or four pieces (each 4 feet long) around the end of a pine stick, about 2 inches in diameter and 4 feet long; cover the whole with a mixture of equal parts of sulphur and mealed powder, moistened with brandy, and fill the intervals between the cords with a paste of 3 parts of sulphur and 1 of quicklime. When it is dry, cover the whole with the following composition: 3 parts of pitch, 3 parts of Venice turpentine, and ½ part of turpentine. Torches are lighted at the top, which is cracked with a mallet; they burn from one and a quarter to two hours. In lighting the march of a column, the men who carry torches should be about 100 feet apart.

OFFENSIVE AND DEFENSIVE FIREWORKS.—The principal preparations of this class, employed in modern warfare, are *bags of powder* and the *light-barrels*. BAGS OF POWDER may be used to blow down gates, stockades, or to form breaches in thin walls. The *petard* was formerly employed for these purposes, but it is now generally thrown aside. From trials made in England, it has been shown that a sand-bag (covered with tar, and sanded to prevent it from sticking) containing 50 pounds of powder, has sufficient force to blow down a gate formed of 4-inch oak scantling, and supported by posts 10 inches in diameter and 8 feet apart; and a bag containing 60 pounds of powder, and weighted with two or three bags of earth, has sufficient force to make a large hole in a 14-inch brick wall. The effect of the explosion may be much increased by making three sides of the bag of leather, and the fourth of canvas, which should rest against the object. A suitable means of exploding bags of powder is a *time-fuse*, or the ordinary *safety-fuse* for blasting rocks. A LIGHT-BARREL is a common powder-barrel pierced with numerous holes, and filled with shavings that have been soaked in a composition of pitch and rosin; it serves to light up a breach, or the bottom of a ditch.

ORNAMENTAL FIREWORKS.—Ornamental fireworks are employed to celebrate great events, as victories, treaties of peace, funerals, etc. They are divided into *fixed pieces*, *movable pieces*, *decorative pieces*, and preparations for *communicating fire* from one part of a piece to another. The different effects are produced by modifying the proportions of the ingredients of the burning composition so as to quicken or retard combustion, or by introducing substances that give color and brilliancy to the flame. The fixed pieces are *lances*, *petards*, *gerbes*, *flames*, etc. LANCES are small paper tubes from .2 to .4 inch diameter, filled with a composition which emits a brilliant light in burning. Instead of a single composition, each lance may contain two or more compositions, which in turn emit different-colored flames. The case should be as thin as possible, in order that the color of the flame of the composition may not be affected by that of the paper. Lances are generally employed to form figures; this is done by dipping one end in glue, and sticking them in holes arranged after a certain design, in a piece of wood-work. PETARDS are small paper cartridges filled with powder. One end is entirely choked, and the other is left partially open for the passage of a strand of quick-match, designed to set fire to the powder. A petard is usually placed at the fixed end of a lance, that the flame may terminate with an explosion; they are also used to imitate the fire of musketry. GERBES are strong paper tubes or cases filled with a burning composition. The ends are tamped with moist plaster of Paris or with clay; through one a hole is bored extending a short distance into the composition, that it may emit a long sheaf or *gerbe* of brilliant sparks. The diameter of the case is about one inch, and the length depends upon the required time of burning. The number of blows to each ladleful of composition is ten. Gerbes are secured to the frame of the piece with wire or strong twine, and pointed in the direction that the flame is to take. FLAMES consist of lance or star composition, driven into paper cases or earthen vases. The diameter of the burning surface should be large, to give intensity to the flame. Lance-composition is driven dry, and with a slight pressure. Star-composition should be moistened, and driven with greater pressure than the preceding.

The movable pieces are the *sky-rockets*, *tourbillions*, *saxons*, *jets*, *Roman candles*, *paper shells*, etc. SKY-ROCKETS are the same as the signal-rockets, except that the composition is arranged to give out a more brilliant train of fire. The TOURBILLION is a case filled with sky-rocket composition, and which moves with an upward spiral motion. The spiral motion is produced by six holes—two lateral holes (one on each side), for the rotary motion, and four on the under side, for the upward motion. It is steadied by two wings formed by attaching a piece of a hoop to the middle of the case, and at right angles to its length. To give it a proper initial direction, a hole is made through the center of the case to fit on a vertical spindle, which is fastened to an upright post. The SAXON is the same as the tourbillion, except that it is only pierced with the central and two lateral holes, and has no wings. The central hole is placed on a horizontal spindle, and the piece has the appearance of a revolving sun. JETS are rocket-cases filled with a burning composition; they are attached to the circumference of a wheel, or the end of a movable arm, to set it in motion. They also produce the effect of gerbes; and to increase the circle of fire, they are inclined to the radius at an angle of 20° or 30°. A ROMAN CANDLE is a strong paper tube containing stars, which are successively thrown out by a small charge of powder placed under each star. A slow-burning composition is placed over each star to prevent all of them from taking fire at once. PAPER SHELLS are filled with decorative pieces, and fired from a common mortar. It contains a small bursting-charge of powder, and has a fuse regulated to ignite it when the shell reaches the summit of its trajectory. The shell is made by pasting several layers of thick paper over a sphere of wood, cutting the covering thus formed in halves, so as to remove the sphere, joining the halves again, and pasting paper over them until the thickness is sufficient to resist the charge of the mortar. Decorative pieces are the *stars*, *serpents*, *marrons*, etc., described under the head of Rockets.

Preparations for communicating fire from one piece to another are the *quick-match*, *leaders*, *port-fires*, and *mortar-fuses*. The LEADER is a thin paper tube containing a strand of quick-match, and it is united to a piece by pasting pieces of paper over the joint. If the piece is to be fired at once, the leader may be omitted, and strands of quick-match tied together used in its place.

The foregoing pieces are generally mounted on pieces or frames of light wood, and are susceptible of being combined so as to produce a great variety of striking effects. See *Blue-light*, *Carcass-compositions*, *Colored Fires*, *Fire-ball*, *Friction-primers*, *Fuse*, *Gold Rain*, *Hot-shot*, *Incendiary match*, *Lances*, *Lea* *ders, Light-balls, Light-barrel, Lights, Marrons, Petards, Pitched Fascines, Port-fires, Pyrotechny, Quick-match, Rock-fire, Roman Candle, Serpents, Signal-rocket, Slow-match, Stars, Streamers, Sun-cases, Tarred Links, Torches, Tourbillion, Wheel-cases*, and *Wooden Shells.*

FIRING.—The act of discharging fire-arms. Firings are either direct or oblique, and are executed as follows:

The Direct Fire.—The Instructor commands: 1. *Fire by squad*, 2. *Squad*, 3. READY, 4. AIM, 5. FIRE, 6. LOAD. The commands *ready, aim, fire*, and *load* are given with sufficient intervals to allow them to be executed as officially stated. The rear-rank men incline the upper part of the body forward, so that their pieces may reach as far as possible beyond the front rank. Upon the completion of the load, the Instructor continues the firing by the commands: 1. *Squad*, 2. AIM, 3. FIRE, 4. LOAD. To cease firing, the Instructor commands: 1. *Cease*, 2. FIRING. At this command, the men cease firing, reload their pieces if unloaded, and afterward bring them to a *carry. This rule is general.*

Oblique Firings.—The oblique firings are executed to the right and left by the same commands as the direct fire, except that the command *aim* is preceded by the command *right* (or *left*) *oblique*. At the command *right oblique*, the men of both ranks cast their eyes to the right and look steadily at the object. At the command *aim*, the front-rank men aim obliquely to the right, without deranging the feet; each rear-rank man aims obliquely to the right, keeping the right foot in its place, at the same time advancing the left foot about eight inches to the right and front, the toe pointing in the direction he is to fire, the upper part of the body inclining forward, the left knee slightly bent. If the command be *left oblique*, the men of both ranks cast their eyes to the left; the rear-rank men at the same time raise their pieces to a vertical position. At the command *aim*, the front-rank men aim obliquely to the left, without deranging the feet; each rear-rank man, keeping the right foot in its place, brings down his piece to the left of his front-rank man, at the same time advancing his left foot about eight inches to the left and front, the toe pointing in the direction he is to fire, inclining the upper part of the body forward, the left knee slightly bent. In recovering arms from the left oblique, each rear-rank man, at the command *recover*, raises his piece to a vertical position, and, at the command *arms*, comes to the position of ready. In both cases at the command *load*, the men of each rank come to the position of load, as prescribed in the direct fire, the rear-rank men bringing back the foot in advance to the proper position in loading, and bringing back their pieces as in recovering arms.

To Fire by File.—The Instructor commands: 1. *Fire by file*, 2. *Squad*, 3. READY, 4. COMMENCE FIRING. At the fourth command, the file on the right aim and fire, reload, fire again, and so on. The second file aim at the instant the first lower their pieces to the position of the first motion of load, fire, and conform to what has been prescribed for the first file, and so on to the left. After the first fire each man loads and fires independently of the others.

To Fire by Rank.—The Instructor commands: 1. *Fire by rank*, 2. *Squad*, 3. READY, 4. *Rear-rank*, 5. AIM, 6. FIRE, 7. LOAD. The rear rank aims, fires, and loads, as already explained. As soon as the Instructor sees several pieces of the rear rank in the position of ready, he commands: 1. *Front rank*, 2. AIM, 3. FIRE, 4. LOAD. The Instructor causes the ranks to alternate in firing, until he commands: 1. *Cease*, 2. FIRING.

To Fire Kneeling.—The pieces being loaded, and at a carry, the Instructor commands: 1. *Fire kneeling*, 2. KNEEL. Bring the left toe squarely to the front, and plant the right foot so that the toe shall be about twelve inches to the rear and twelve inches to the left of the left heel, the feet at right angles; kneel on the right knee, bending the left; drop the muzzle to the front, support the piece with the left hand at the lower band, the forearm resting on the left knee, the right hand grasping the small of the stock, muzzle at the height of the chin. If formed in two ranks, at the first command for kneeling, the rear-rank men take a side-step to the right. After rising they take a side-step to the left and cover their front-rank men. The firings are executed by the same commands as when standing. The piece is brought to a ready by simply cocking it, and is supported in aiming by the left elbow, resting on the left knee. To load, lower the piece, support it with the left hand at the lower

Fire Kneeling.

band, the left forearm resting on the left knee, the barrel sloping downward. In firing obliquely, the rear-rank men aim through the same intervals as when standing, and do not support the left elbow on the left knee.

To Fire Lying Down.—The squad being in one rank, pieces loaded and at an order, the Instructor commands: 1. *Fire lying down*, 2. LIE DOWN. At the second command, each man drops on his knees, places his left hand, well forward, on the ground, and lies flat on his belly; the piece is lowered at the same time with the right hand, the toe and muzzle resting on the ground, the barrel up, the left hand at the lower band, the left elbow on the ground, the right hand at the small of the stock, opposite the neck. At the command *commence firing*, cock the piece; raise it with both hands, press the butt against the shoulder, and, resting on both elbows, aim and fire. To load the piece, steady it at the lower band with the left hand, the toe and muzzle resting on the ground, insert the cartridge with the right hand. To rise, the Instructor commands: 1. *Squad*, 2. RISE. Draw back the piece slightly; grasp it at the lower band with the right hand, and bring it to a vertical position, barrel to the rear, the butt opposite the neck; with the aid of both hands raise the body to a vertical position, on the knees; bring back the piece, the toe in a line with the right knee; throw the weight of the body backward, rise on the balls of both feet, and return to the position of order arms. Troops will never be permitted to fire lying down when the enemy, advancing to the attack, arrives within effective range. See *Fire.*

FIRING-BATTERY.—The efficiency of a mine or system of mines depends upon the accuracy and certainty with which they may be discharged at the right moment, this moment being when the hostile vessel is directly over any particular mine of the group. This may be done at will, the position of the ship having been determined by intersection, or the vessel herself may be made to complete the circuit by striking a circuit-closer.

The testing-room should be in the most secure part of the work. It should be about 16 feet square, with a suitable store-room attached. From the testing-room a gallery, about 4 feet wide by 5 high, passes out through or under the fort. In this gallery are placed frames for supporting the cables, so arranged that there will be no confusion as to the identity of the cables. The frames should be of bronze; iron is apt to oxidize, and wood is liable to decay and render constant repairs necessary. The frames occupy half the breadth of the gallery, leaving the other half for access and examination of the cables. Each cable is attached to a binding-screw of the testing-table, the binding-screws being numbered to correspond with the mines.

In the testing-room is the apparatus for producing the agent by which the mines are to be exploded. This may be frictional electricity, a magnet current generated by a dynamo-electrical machine, but usually it is a galvanic current similar to that for electric-telegraph purposes. The main conditions for such a battery are that it should remain constant—that is, that it should be capable of being allowed to remain mounted and ready for use for say one month—and that it shall generate a sufficient quantity of electricity to allow of a certain amount of leak or fault in a cable and yet fire a fuse beyond the leak.

The Leclanché battery is the one best adapted and most generally used. The advantages possessed by it are the absence of chemical action when the battery-circuit is not complete, and consequently there is no waste of material; it requires but little looking after; it may be kept ready for action in store without in any way deteriorating; and, finally, it is comparatively inexpensive.

FIG. 1.

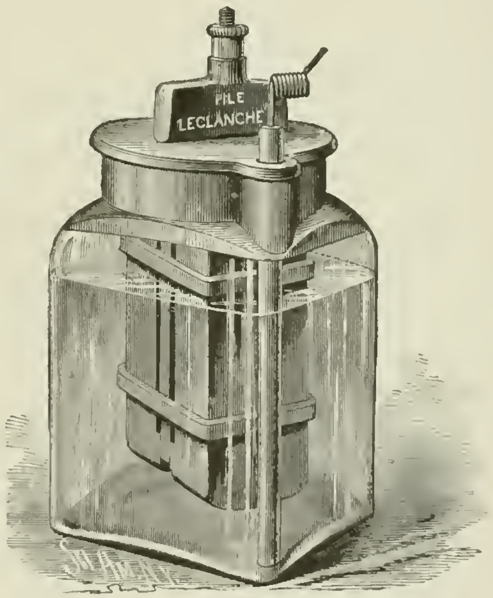

FIG. 2.

Fig. 1 shows the old form or *disque* battery, so successfully employed in extensive mining operations. Fig. 2 shows the improved form, or the Leclanché prism-battery. In this battery the porous cup is dispensed with, and in its place is substituted a pair of compressed "prisms" or plaques which are simply attached to the carbons by means of two strong rubber bands. The prisms contain all of the materials heretofore employed in the porous cup, combined with others not before used, compressed into this compact and convenient form by powerful hydraulic machinery.

The positive pole is composed of a plate of carbon inserted between and in connection with two compressed prisms of peroxide of manganese and carbon, combined with other materials, the three being held firmly together by rubber bands. The negative pole is composed of a pencil of amalgamated zinc. The two poles are placed in a solution of sal-ammoniac and water, contained in a glass jar with a cover, through which the carbon head and the zinc project. When the elements have become exhausted from long service, or other cause, to renew the battery it is only necessary to take off the prisms, soak the carbon (below the bead) in hot water, attach new prisms, and set up as before, with a sufficient quantity of new zinc and sal-ammoniac.

The firing-battery should be suited to the nature of the fuses employed, and should possess considerable excess of power in order to overcome accidental defects, such as increased resistance in the communications, or defective insulation in the electric cable in connection with the mine. A battery just sufficiently powerful to fire a fuse on the shore, with the electric cable, etc., in circuit, but not submerged, would not be unlikely to fail after the cable has been submerged in sea-water. In such a case it is recommended that the battery-power determined by such an experiment on shore be doubled for actual work. For all practical purposes this test can be made by firing a fuse of known quality through a resistance equivalent to that of the cable. Double the number of cells necessary to effect this would be required for the submerged cables, etc. See *Galvanism.*

FIRING-PARTY.—Those who are selected or detailed to fire over the grave of any one buried with military honors.

FIRING PIN.—That part of the breech-mechanism whose function is to explode the cartridge. It ordinarily has a slot cut in it near the head for the end of a screw which, projecting into it, prevents it from coming out of place. The hammer having been drawn back to full-cock, and the trigger pulled, the head of the *firing-pin* is thrown forward, strikes the head of the cartridge and explodes it. See *Hadley Firing-pin* and *Springfield Rifle.*

FIRST SERGEANT.—The ranking Non-commissioned Officer in a company. He has immediate charge of all enlisted men of the company and company property; has command of it during formations, and calls the roll. He also makes all details, keeps the roster, etc. See *Orderly Sergeant.*

FISCAL YEAR.—In the United States army, funds appropriated for any given fiscal year cannot be used to liquidate liabilities incurred in any other fiscal year, nor can funds be used for any other class of expenditure than that to which they were appropriated. At the termination of each fiscal year all amounts of moneys that are represented by certificates, drafts, or checks, issued by the Treasurer, or by any Disbursing

Officer of any Department of the Government upon the Treasurer or any Assistant Treasurer, or designated depositary of the United States, or upon any national bank designated as a depositary of the United States, and which shall be represented on the books of either of such offices as standing to the credit of any Disbursing Officer, and which were issued to facilitate the payment of warrants, or for any other purpose in liquidation of a debt due from the United States, and which have for three years or more remained outstanding, unsatisfied, and unpaid, are deposited by the Treasurer, to be covered into the Treasury by warrant, and to be carried to the credit of the parties in whose favor such certificates, drafts, or checks were respectively issued, or to the persons who are entitled to receive pay therefor, and into an appropriation account to be denominated "outstanding liabilities." The payee or the *bona-fide* holder of any draft or check the amount of which has been deposited and covered into the Treasury pursuant to the above paragraph, on presenting the same to the proper Officer of the Treasury, is entitled to have it paid by the settlement of an account and the issuing of a warrant in his favor, according to the practice in other cases of authorized and liquidated claims against the United States.

The following well-known Treasury regulations bear on this subject:

1. Any Treasury draft or any check drawn by a public Disbursing Officer still in service, which shall be presented for payment before it shall have been issued three full fiscal years, will be paid in the usual manner by the office or bank on which it is drawn, and from funds to the credit of the drawer. Thus any such draft or check issued on or after July 1, 1873, will be paid as above stated until June 30, 1877, and the same rule will apply for subsequent years.

Any such draft or check which has been issued for a longer period than three full fiscal years will be paid only by the settlement of an account as provided by law; and for this purpose the draft or check will be transmitted to the Secretary of the Treasury for the necessary action.

2. The reports of independent Treasury Officers, national-bank depositaries, and public Disbursing Officers will be rendered promptly to the Secretary of the Treasury at the close of each fiscal year.

3. Whenever any Disbursing Officer of the United States shall cease to act in that capacity, he will at once inform the Secretary of the Treasury whether he has any public funds to his credit in any office or bank, and, if so, what checks, if any, he has drawn against the same which are still outstanding and unpaid. Until satisfactory information of this character shall have been furnished, the whole amount of such moneys will be held to meet the payment of his checks properly payable therefrom.

4. At the close of each fiscal year the Treasurer, the several Assistant Treasurers, and designated and national-bank depositaries, will also render to the Secretary of the Treasury a list of all Disbursing Officers' accounts still unclosed which have been opened on the books of their respective offices or banks more than three fiscal years, giving in each case the name and official designation of the officer, the date when the account with him was opened, and the balance remaining to his credit.

5. In case of the death, resignation, or the removal of a public Disbursing Officer, any check previously drawn by him and not presented for payment within four months of its date will not be paid until its correctness shall have been attested by the Secretary or Assistant Secretary of the Treasury.

FISHERMAN'S KNOT.—A knot used in pontoning to fasten the cables to the rings of the anchors. See *Knots*.

FISHING-SPARS.—In artillery material, the spars of wood placed parallel to the spars to be strengthened, by lashing them to one another.

FISHTAIL WIND.—An expression employed in target-practice with small-arms for a rear wind which is variable in direction.

FISSURE.—A small chasm where a small breach has been made, as in a fort, citadel, etc.

FISTULA.—In farriery, the name given to an abscess usually situated on the withers of a horse, and discharging pus. Sometimes it appears on the head, when it is called poll evil.

FITCHY.—Crosses are said, in Heraldry, to be fitchy when the lower branch ends in a sharp point. Crosses are supposed to have been so sharpened to enable the primitive Christians to stick them into the ground for devotional purposes. Also written *Fitché*.

FITTINGS.—The name given to certain fixtures in a barrack or on board a military transport for the purpose of keeping up a current of pure air, and for receiving the equipments and arms.

FITZROY DEFLECTOR.—An instrument designed to prevent the need of making a correction for the inclination of the trunnions. It consists of a block (capable of movement round a pin fixed on the breech of the gun) containing the sight-slot, which is kept making the same permanent angle of deflection with the perpendicular to the axis of the trunnions by means of a heavy bob underneath, however much the inclination of the trunnions may alter. A spirit-level is also added.

FIX BAYONET.—A command in the Manual of Arms, executed as follows: The Instructor commands, 1. *Fix*, 2. BAYONET. Grasp the piece with the left hand, forearm horizontal; carry it to the left side, the butt striking the ground about eight inches to the rear of the left toe, the piece inclined to the front, the left wrist resting against the thigh; carry the right hand to the shank of the bayonet. (Two.) Draw the bayonet from the scabbard, and fix it on the end of the barrel; drop the right hand by the side.

1. *Carry*, 2. ARMS. Raise the piece with the left hand and place it against the right shoulder; resume the carry with the right hand. (Two.) Drop the left hand by the side. See *Manual of Arms*, Fig. 6.

FIXED AMMUNITION.—When the cartridge is attached to the projectile, the two together are termed *fixed ammunition;* this is employed for the service with boat-howitzers. It has the advantage of great convenience in the hurried preparations that frequently precede boat-operations, and the guns can be served the more rapidly with fixed ammunition; simultaneous loading is more simple, and the cartridge is sure to be placed correctly in the bore, and not with the choked end first, as is sometimes the case when the projectile and the cartridge are separate. Fixed ammunition has, however, the great disadvantage that in packing or stowing much greater space is required, and it is more difficult to arrange and to preserve.

The following implements are required in *fixing* ammunition:

Barrels for powder; 1 *funnel;* 1 *set of powder-measures;* 1 *straight-edge*, to strike the measures with; *barrels; tubs*, formed of barrels sawed in two, or *boxes*, for the cartridge-bags; 2 *paulins;* 2 *benches;* 12 *choking-sticks*, 6 with holes in them and 6 slit; 6 *knives;* 6 *hand-barrows* with 4 legs and a box, and *paulins* to cover them; caliber-gauges for the cartridge-bags and for fixed ammunition (they may be made of wood); 6 *stools;* 1 *wheel-barrow;* 1 *mallet;* 1 *copper chisel;* 1 *copper drift*, or a *wrench*, to open the powder-barrels.

In fixing shot or case for smooth-bore field-guns, the bags should be filled in the small magazine or filling-room. The assistant holds the pipe of the funnel in the mouth of the bag with both hands, the bag pressed close against the pipe. The gauger heaps up the measure with powder, strikes it level with the straight-edge, and pours it into the funnel. When about 25 bags are filled the gauger takes a filled bag with one hand, squeezing the bag upon the powder; he gives it a blow with the other hand on the top and bottom of the bag, twisting the mouth of the bag down upon the powder at the same time; he then tries it with the small gauge through which it should pass with not more than .25 inch play; should it not do this, the bag is emptied and rejected. These bags, filled and gauged, are placed upright in a tub or box and carried by the gaugers into the finishing-room, where the men are placed in pairs, sitting astride on a bench facing each other. One of them opens a bag and levels the powder, the other inserts the sabot of a strapped shot square upon the powder and draws up the end of the bag over the shot; the first man passes about 4 feet of twine through the pierced stick and makes two turns and a double hitch with the end at the top of the sabot; he makes a knot in the end of the twine, inserts it into the slit in the other choking-stick, and tightens the double hitch by rolling the twine on the sticks and bearing upon the sabot; he then takes out the end of the twine from the slit, ties it in a hard knot, which he tightens with the assistance of the choking-stick, and cuts the twine off near the knot. The second man turns down the mouth of the bag over the sabot, and the first makes a similar tie in the groove; he makes another tie below the sabot, the twine being lodged between it and the powder to prevent the latter from sifting in between the bag and the sabot; he then runs the paper cylinder over the cartridge and sabot, leaving about two inches of the end of the cartridge uncovered, and he makes a tie similar to the others in the groove of the sabot. He now holds the shot in the left hand and examines it, striking the sabot with the right hand, if necessary, to bring it straight; if the shot be properly fixed, the sabot and the bag will have the same axis; the seams should be between two straps, and the knots should be neither on the seams nor on the straps. The assistants pass the cartridges through the large gauge, which is .04 inch larger than the large gauge for the shot. If the size be correct, they put on the paper cap, lay the cartridges on their sides in the box of the hand-barrow, and carry them to the magazine. Those which will not pass through the gauge are handed back to the fixers, who sever the strings and put them up anew.

Canisters for smooth-bore field-guns are fixed in the same manner as shot, except that the first tie is made in the upper groove of the sabot; the cylinder is tied in the lower groove. The caps must be cut somewhat shorter than those for shot-cartridges. *For mountain-howitzers* the sabots have but one groove, the first tie is omitted, and the cartridge is covered with a cap only. When the shot is attached to the sabot by a single band of canvas, or when it is placed in the sabot without any strap, the cartridge-bag is drawn over it and tied on top; for this purpose the bag should have an additional length of from 2½ to 3 inches. When sabots cannot be obtained, place upon the powder one layer of tow about .2 inch thick, forming a bed for the shot; tie the bag over the shot and around the tow; the bag requires to be 1 inch longer than for strapped shot. See *Ammunition* and *Field and Mountain Ammunition.*

FIXED BATTERY.—The batteries used during the second period of siege-operations are both fixed and movable. The fixed batteries contain the siege-guns and mortars of the heaviest caliber and longest range; whilst the movable batteries will consist of field-guns and small mortars which can take up temporarily any favorable positions for damaging the defenses. As a general rule the fixed gun-batteries should be placed in enfilading positions whenever such can be found for them, delivering their fire always within the interior slope of the face enfiladed, and in preference taking a slant reverse direction on the terre-plein of the face. Parts of the defenses which cannot be reached by enfilade must be counter-battered by batteries which can obtain a full-front or a slant-front view upon them. The mortar-batteries will receive such positions as are most favorable for reaching the interior of the defenses; preference being given to those in which the longest lines of the defenses can be brought within the range and direction of the shells; avoiding, whenever practicable, throwing them across the positions occupied by the approaches, so as to insure a shell being landed within some point of the defenses, and to avoid the accidents from shells falling short of their butt or bursting prematurely. The positions of the fixed batteries of rifled guns and heavy mortars will be usually along the position of the first parallel and some 30 or 40 yards in advance of it, so that its service shall not interfere with that of the parallel, nor the service of the latter with it—a point of great importance for the efficient service of each; and being in advance of the parallel, the troops in the latter will not be annoyed by the discharge of the guns, which they might be were they in their rear. As the ricochet of rifled guns with the elongated shot is uncertain, and, from the great range at which the guns fire, the plunge of the projectile would be necessarily great and unfavorable to ricochet, positions for fixed enfilading batteries of smooth-bore siege-guns may be taken either in advance of the second parallel or, better, in some of the demi-parallels, so as to bring them within some 500 yards of the line to be enfiladed, as the range very favorable for the ricochet of these pieces.

The number of guns in each enfilading battery will depend upon the extent of terre-plein within the works upon which an enfilade or a slant reverse fire can be obtained. Usually the number of guns should not exceed seven, nor be less than three; the number being regulated by the importance to the besieged of the line enfiladed. In each counter-battery there should be at least as many guns as the defenses can bring to bear upon it; always enough to completely control the fire of the point counter-battered. Whilst batteries containing a large number of guns are exposed to greater casualties than smaller ones, weak batteries are liable to be silenced by a concentrated fire upon them from the defenses. As a general rule, batteries at different distances should be so placed that the more advanced should not be in the line of fire of those in the rear. The danger from accidents from a violation of this rule is not very great if the batteries are several hundred yards apart, and the point fired at distant; or until the trenches get near the position of the third parallel. At this stage great precaution is necessary in regulating the fire so that the shot may not fall into or explode too near the trenches. See *Batteries* and *Movable Battery.*

FIXED PIVOT.—The fixed point about which any line of troops wheels. This point is marked by a soldier or guide who stands fast or marks time while the line wheels.

FLAG OF PROTECTION.—It is customary to designate by certain flags (usually yellow) the hospitals in places which are shelled, so that the besieging enemy may avoid firing on them. The same has been done in battles, when hospitals are situated within the field of the engagement. Honorable belligerents often request that the hospitals within the territory of the enemy may be thus designated, so that they may be spared. An honorable belligerent allows himself to be guided by flags or signals of protection as much as the contingencies and the necessities of the fight will permit. It is justly considered an act of bad faith, of infamy or fiendishness, to deceive the enemy by flags of protection. Such an act of bad faith may be good cause for refusing to respect such flags. The besieging belligerent has sometimes requested the besieged to designate the buildings containing collections of works of art, scientific museums, astronomical observatories, or precious libraries, so that their destruction may be avoided as much as possible.

FLAG OF THE PROPHET (Sanjak-Sherif).—The sacred banner of the Mohammedans. It was originally of a white color, and was composed of the turban of the Koreish, captured by Mohammed. A black flag was, however, soon substituted in its place, consisting of the curtain that hung before the door of Ayeshah, one of the Prophet's wives. This flag, regarded by the Mohammedans as their most sacred relic, first came into the possession of the followers of Omar at Damascus; it afterwards fell into the hands of the Abbasi; then passed into those of the Caliphs of Bagdad and Kahira; and, at a later period, was brought into Europe by Amurath III. It was covered with forty-two wrappings of silk, deposited in a costly casket, and preserved in a chapel in the interior of the seraglio, where it is guarded by several Emirs, with constant prayers. The banner unfolded at the commencement of a war, and likewise carefully preserved, is not the same, although it is believed by the people to be so.

FLAG OF TRUCE.—A white flag carried by an officer sent to communicate with the enemy. The bearer cannot insist upon being admitted. He must always be admitted with great caution. Unnecessary frequency is carefully to be avoided. If the bearer of a flag of truce offer himself during an engagement, he can be admitted as a very rare exception only. It is no breach of good faith to retain such a flag of truce, if admitted during the engagement. Firing is not required to cease on the appearance of a flag of truce in battle. If he, presenting himself during an engagement, is killed or wounded, it furnishes no ground of complaint whatever. If it be discovered, and fairly proved, that a flag of truce has been abused for surreptitiously obtaining military knowledge, the bearer of the flag thus abusing his sacred character is deemed a spy. So sacred is the character of a flag of truce, and so necessary is its sacredness, that while its abuse is an especially heinous offense, great caution is requisite, on the other hand, in convicting the bearer as a spy. See *Truce*.

FLAGS.—Cloths of light materials, capable of being extended by the wind, and designed to make known some facts or wants to spectators. In the Army a flag is the ensign carried as its distinguishing mark by each regiment; and also a small banner, with which the ground to be occupied is marked out. In the Navy the flag is of more importance, often constituting the only means vessels have of communicating with each other or with the shore. For this purpose devices of conspicuous colors (usually black, white, red, yellow, or blue) are hoisted at the mast-head or at the gaff. The flags having three forms, a very few patterns in each shape give sufficient combinations of three or four flags to express any letter or word in the language. The flag is also a sign of the rank of the principal person on board a vessel, as the "Royal Standard," containing the Arms of the United Kingdom, which is only hoisted when a member of the Royal Family is on board; the "Anchor of Hope," on a red ground, denoting the Admiralty; the Pennant, which specifies the ship of war; and the Ensign, which denotes the nation. Naturally the regular English flag was used by the Colonies in their early days, and that was commonly the cross of St. George. The Puritan spirit was shown when Endicott, the Governor of Massachusetts, cut the cross from the flag because it was a Romanist emblem. The Colonial flags varied in color, it being sufficient if ground and cross differed. Now and then a pine-tree was figured in the upper left-hand quarter of the cross, and one flag had only this tree for a symbol. When Sir Edmund Andros was Governor he established a special flag for New England, a white field with a St. George cross, and in the center "J. R.," *Jacobus Rex* (James, King), surmounted by a crown. The Revolution brought in all manner of devices for flags and banners, the larger portion bearing mottoes more or less defiant of the Foreign Government. Soon after the engagement at Lexington the volunteers from Connecticut put on their flag the Arms of the Colony, with the legend "*Qui transtulit, sustinet*" (He who brought us over will sustain us). The Colonial flag of New Amsterdam (substantially the present Arms of New York City) was carried by armed vessels sailing out of New York—a beaver being the principal figure, indicative of both the industry of the Dutch people and the wealth of the fur trade. The day after the battle of Bunker Hill, Putnam displayed a flag with a red ground, having on one side the Connecticut motto, and on the other the words "An appeal to Heaven." The earliest vessels sailing under Washington's authority displayed the Pine-tree flag. An early flag in the Southern States was designed by Colonel Moultrie and displayed at Charleston in September, 1775. It was blue, with a white crescent in the upper corner next the staff; afterwards the word "Liberty" was added. At Cambridge, Mass., January 2, 1776, Washington displayed the original of the present United States flag, consisting of thirteen stripes of red and white, with a St. Andrew cross in place of the stars. The Rattlesnake flag was used to some extent in two forms: in one the snake was intact, and under the figure the words "Don't Tread on Me;" in the other form the snake was in thirteen pieces, and the legend was "Join or Die;" and in some cases the snake had thirteen rattles. Ten days after the Declaration of Independence, Congress directed the style of the flag of the United States, as heretofore described, with its later modifications. By the War Department the stars in the union are usually so placed as to form one large star. In the Navy the stars are in straight lines, perpendicular and horizontal. The Union Jack is a blue ground with all the stars but no stripes. During the War of the Rebellion the Seceding States had a number of distinct flags. Early in 1861, however, their Congress decided upon what was popularly called the "Stars and Bars," which was composed of three broad horizontal bars, the two outer ones red and the middle one white, with a blue "union" containing nine stars in a circle. Some variations were afterwards made, but they need not be noticed. There are many flags which designate special or personal position or authority. Among such are Royal Standards, Flag Officers' flags, etc. An Admiral's flag is usually the flag of the country which such an Admiral serves, with the exception of the "union." The flag of the Admirals, Vice Admirals, and Rear Admirals of the United States is rectangular, and consists of thirteen alternate red and white stripes. The Admiral hoists this at the main; the Vice Admiral at the fore; the Rear Admiral at the mizzen. Should there be two Rear Admirals present, the Junior hoists at the mizzen a flag similar to the one described, with the addition of two stars in the left-hand corner. The Commodore's flag differs from that of the Admiral in form alone, being swallow-tail instead of rectangular. Should the President go afloat, the American flag is carried in the bow of his barge or hoisted at the main of the vessel on board of which he may be. In foreign countries the Royal Standard is displayed at ceremonies in honor of the Sovereign or at which the Sovereign may be present. A flag placed midway on the staff, or "half-mast," is a sign of mourning. A flag reversed or upside down indicates distress. Salutes are made by dipping the flag by hauling it down a short distance and immediately raising it several times in succession. See *American Flag*, *Banner*, *Ensign*, *Garrison-flag*, *Pennon*, *Post-flag*, *Red Flag*, *Standard*, *Storm-flag*, and *Union Jack*.

FLAG-STAFF.—A mast or pole on which a flag or standard is hung. One is allowed to each fort or fortress, and to the Governors of the several English Dependencies, to Commanders-in-Chief, and to officers commanding divisions or districts of the army.

FLAIL.—An ancient weapon composed of a shaft and several whips, the latter either with or without iron points; or else of the shaft, to which was fastened a chain ending in an iron ball, or a wooden one studded with iron. The flail, which was well known in Switzerland and Germany during the fifteenth century, was also used in England since the period of the Norman Conquest, and existed during the reign of Henry VIII., though then but little used, and only in the trenches and on board ships. The military flail with a short handle belonged more particularly to Russia and Japan.

The Admiral's Flag, pro tem, is cut as a Pennant.

FLAM.—A beat or tap upon the drum which was formerly used in the British army when regiments were going through their drill or exercise, every formation being done by tap or beat upon the drum. It was likewise beaten in firing-practice whenever the target was struck.

FLAMBEAU.—A variety of torch made of thick wicks, covered with wax, and used in the streets at night, at illuminations, and in processions.

FLAME-SWORD.—A weapon intended to be used with both hands, and employed in the sixteenth century. This sword should not be mistaken for the *flamberg*.

FLANCH—FLANGE.—The projecting rim of metal on the circumference of a wheel or cylinder to serve as a bearing; for example, the rim on the tire of railway-wheels. The rim of metal round the mouth of gun-caps used with percussion-muskets is called a flange.

FLANCHARDS.—The side-pieces of ancient horse-armor, which joined the front-plate or the breast-piece to the thigh-pieces and croupière.

FLANCHES.—In Heraldry, flanches are composed of arched lines drawn from the upper angles of the escutcheon to the base-points. The arches of the flanches almost meet in the center of the shield. The flanches are an ordinary little used in Scotch Heraldry. Also written *Flanques*.

FLANCHIERE.—A part of horse-armor which covered the flanks and croup as far as the houghs.

FLANCONADE.—In fencing, a term commonly applied to a thrust in the side. See *Fencing*.

FLANGED SYSTEM OF RIFLING.—This system embraces all projectiles upon the cylindrical portion of which are projections which in loading are intended to be inserted into corresponding grooves in the bore of the gun. Under this system may be classed all those projectiles which have projections in the form of studs, ribs, or flanges on their surfaces intended to take the grooves in loading. And it may also be said to comprise all mechanically fitted projectiles like the Whitworth; for the salient departures from a circle, in cross-section of the projectile, may be regarded as flanges, while the corresponding angles in cross-section of the bore, and into which these flanges fit, constitute the grooves. The various modifications of this common system are very great, and none of them can be said to have given entire satisfaction, while all of them have revealed serious faults and shortcomings.

The evident advantages of this system are economy, simplicity, and durability of the projectile. The rifle-motion is communicated with great certainty and regularity. The projectile does not expand by the explosion, and hence gets more windage as the bore warms. As the gun expands and gets weaker, its safety-valve gets larger.

The chief objections are, that both projectile and bore being hard, fracture of one or the other is liable to occur from a projectile jamming; and that unless the bore be made of very hard material, it will be rapidly worn by the friction of the projectile. See *System of Rifling*.

FLANK.—The right or left side of a body of men or a place. Flank presupposes a formation more or less deep. A flank-march is upon the prolongation of the line to which a body faces. Thus, when we say the enemy, by a flank-march, outflanked our right wing, it is understood that the enemy, by marching parallel to our line of battle, put himself in position upon our extreme right. To disturb the flanks of a column or army is to throw an opposing force upon either side of the route that it follows. By this maneuver the march of the column is retarded, or it is forced to a halt; its baggage is sometimes seized, and terror and disorder fall upon the masses. *To flank* is to cover and defend the flanks. We flank a camp by posts placed on the right and left; a corps d'armée is flanked by detachments which take roads parallel to the routes followed by the larger body; smaller columns are flanked by flankers on the right and left, who keep in view the columns, warn them of the approach of an enemy, discover ambuscades, skirmish with them, and fall back when needed upon the mass of the troops.

FLANK-ATTACK.—In warfare, one of the modes of attack whereby the side or flank of an army or body of troops is attacked. Before the introduction of rifled guns and arms, the *attack in front*, by heavy columns of infantry covered by skirmishers and guns, was the usual mode of attack; but since then it has been found, in consequence of the withering and rapid fire of rifles, that, depending alone upon such an attack, a front-advance is attended with extreme danger. Troops advancing in column under such circumstances necessarily break up into skirmishers, the column-form becomes somewhat abandoned, both in the leading columns, supports, and reserves, as each moves up into action. To remedy this, attack in flank or rear is come to be received as the best mode of attack; not that the front-attack is to be altogether given up, for to insure success such an attack is still necessary, though modified; otherwise the enemy would be free to meet and frustrate the flank movements: so that really the attack of the present day is a combination of front and flank.

FLANK-CASEMATE CARRIAGE.—A carriage consisting of two cheeks of wood united by two iron transoms. The chassis consists of two wooden rails three inches apart, and joined by four transoms and assembling-bolts. To the rear end of the top-carriage is attached an eccentric roller, and to each cheek, in front, a roller which, when the eccentric roller is *in gear*, rests on the chassis-rails, giving to the carriage rolling friction. The piece is then easily run in and out of battery, the cannoneers applying themselves to rings and handles on the sides of the cheeks. The front end of the chassis rests on the sole of the embrasure, and is provided with a lunette, through which a pintle drops into the masonry beneath. The rear of the chassis is supported by an iron fork, to the lower extremity of each prong of which is attached a small traverse-wheel. See *Carriage*.

FLANK-COMPANY.—A certain number of troops drawn up on the right or left of a battalion. Thus, when there are grenadiers, they compose the right, and the light infantry the left, flank-company. Grenadiers and light infantry are generally called flank-companies whether attached or not to their battalions; rifle corps are always flankers.

FLANK-DEFENSE. — In fortification, the means adopted in the trace of a work to preserve all parts of it from being unduly exposed to the direct fire of the enemy, such as would be the case if a parapet had alone to protect itself in a direct line upon the besiegers. Again, the face of a work is said to receive *flank-defense*, or to be *flanked*, when the fire of another work is directed parallel or nearly so to its escarp, so as to defend its ditch or the ground in front of it. Any work not so provided would be liable to be captured without difficulty. Take for instance a faultily-constructed work, permitting of the assailants getting close up under the rampart without the defenders seeing them: in this position a few bold, resolute men, with crowbars and a bag of powder, might, by making a cavity in the escarp, destroy a portion of the rampart. To prevent, however, such a possibility, three systems have been devised for giving flanking defense to a permanent work; they are the tenaille system, the bastioned system, and the polygonal system.

FLANKED ANGLE. — In fortification, the angle formed by the flank of the bastion and curtain, or, in other words, that formed by two lines of defense. See *Angle*.

FLANKED DISPOSITION.—In planning or disposing fortifications in relation to the position to be defended, it is very important that the parts shall be so distributed as to obviate certain defects, besides satisfying some other well-known general conditions, such as to bring a *front, flank*, and *cross fire* upon the assailant's columns of attack; or, what is the same, one sheet of fire that will sweep the column from front to rear, another to bear upon each of its flanks so as to cross their fire with each other and with the one from the front. In this way mutual defensive relations are sought to be established between all the parts. To effect this, certain parts are thrown forward towards the enemy to receive his attack; they are denominated *advanced parts;* other portions, denominated *retired parts,* are withdrawn from the enemy, and protect by their fire the advanced parts. This arrangement naturally indicates that the general outline of the plan must present an angular system; some of the angular points, denominated *salients,* being towards the enemy; and others, denominated *re-enterings,* towards the assailed. When such a disposition is made it is denominated a *flanked disposition,* because the enemy's flank is attained by the fire of the retired parts when he is advancing upon the salients. The advanced parts are denominated *faces;* the retired parts, which protect the faces, the *flanks;* the retired part connecting the flanks is the *curtain.* The angle formed by two faces is denominated a *salient angle;* that formed by two retired parts, a *re-entering angle;* and one made by a face and the opposite flank, an *angle of defense.* The line bisecting a salient angle is denominated the *capital;* the distance from a salient to its opposite flank is a *line of defense.*

In planning a work, the interior crest is regarded as the directing line in regulating the dimensions of the faces, flanks, etc., because this line shows the column of fire for the defense. There exists a necessary subordination between the plan, relief, and command of works, which prevents the dimensions of the one being regulated independently of the others; but, without entering into a close examination of this necessary co-relation of the parts, it may be stated generally that faces should vary between thirty and eighty yards, flanks between twenty and forty yards, and curtains should not be less than twelve times the relief. In establishing the co-relations between the different parts of any isolated works or combination of the elements of field fortification, the following facts should, as far as practicable, be observed: 1. The flanks sweep with their fire the ground in front of the faces; remove sectors without fire and dead angles; cross their fire in front of the salients; and take the enemy's column in flank. 2. An acute angle of defense exposes the faces to the fire of the flanks; a too obtuse angle leaves a portion of the ground in front of the face undefended. In the heat of action, the soldier, from his position behind the parapet, naturally brings down his piece, in the act of firing, in a position sensibly perpendicular to that of the interior crest. If every bullet, therefore, took this direction, those delivered just exterior to the parapet flanked would barely clear the men drawn up along it. On this account, and from the fact that unless checked before reaching the ditch the success of the assaulting column is greatly assured, it is better in field-works to make the angles of defense so open that all the fire of the general defense from the flanks shall be thrown from just within the counterscarp outwards; and to insure the flanking of the ditches by cannon, or a body of infantry specially detailed for this duty. 3. The lines of defense should be based upon the skill in handling their weapons of infantry in an ordinary state of efficiency, and allowance must also be made for the ordinary range of distinct vision of such men. The fire of the smooth-bore, with troops in this state, is very effective at 160 yards; and with the best weapons the fire of none but well-trained and special troops can be depended upon much over 300 yards. Particular cases may require the lines of defense to exceed this limit. When they arise they should be specially provided for. The shorter the lines of defense, where the flanking dispositions are good, the longer will the assailant be exposed to the fire of the assailed before he can attain the works, and the greater the chances of checking him. 4. A salient less than 60° is too weak to withstand the effects of weather; the interior space which it incloses is too confined for the maneuvers of the troops; when its faces are not flanked there will be a large sector without fire in front of it. The positions which the assailed can take up to enfilade either face of an acute salient are more favorable to him than in that of an obtuse one, as his guns are thrown farther from and are exposed to a less direct fire of the adjacent face of the salient, and of any other parts of the fortification adjacent to this face. This rule, however, should not be taken as absolute, as many cases may arise where more acute salients can alone be obtained, and in which the troops, being restricted to a passive defense, will require only room enough to load and fire either cannon or muskets. As such salients are necessarily very weak, the approaches to them should be obstructed by every means at hand. 5. The rapidity with which a column of attack approaches, and the short time it remains exposed to the fire of the work unless detained by obstacles in front of the ditch, render its loss, generally, so trifling as not to check its march until it arrives at the crest of the counterscarp. Here, if the ditch is deep, some delay ensues in entering it, during which the column is exposed to a warm fire within short range. When the ditch is entered, a more serious obstacle remains to be encountered in the additional height of the parapet and scarp; and when this obstacle is overcome the enemy presents himself in a fatigued and exhausted state to the bayonets of the assailed, who have mounted on the top of their parapet to meet and drive him back into the ditch. This rule is essential in all isolated works where, from the small size of the garrison, the defense must necessarily be of a passive character, being restricted to a simple repulse of the assailant. 6. Unless the assailed are determined to meet the enemy at the point of the bayonet, they must evacuate their work so soon as he has entered the ditch; a longer delay to retreat would be followed by the most disastrous consequences. The results of innumerable actions prove that the defense with the bayonet is the surest method of repelling the enemy. The assailed, having now become the assailant, are assisted by that moral effect which is produced by a change from a defensive to an offensive attitude. They have, moreover, the advantages of position and freshness over a climbing and exhausted enemy. See *Field-fortification.*

FLANK EN POTENCE.—Any part of the right or left wing formed at a projecting angle with the line. See *Potence.*

FLANKER.—1. A fortification jutting out so as to command the side or flank of an enemy marching to the assault or attack. 2. The dispositions of movable advanced-posts in the directions of the flanks, keeping pace with the progress of the main body, and far enough from it to give it timely warning of a threatened attack, are termed the *flankers.* Generally the head or leading detachment of some force, composed usually of both cavalry and infantry, and if requisite some pioneers, forms the advance of the main body of the advanced-guard, for the purpose of searching all the ground within a dangerous proximity, and of clearing the way for the advancing columns. Through this detachment a communication is kept up with the flankers, and all the ground is thus hemmed in around the advancing column by which an enemy might approach it. The strength of the leading detachment will depend greatly upon the character of the country, and upon the state of the weather and season being more or less favorable to the unobserved approach of an enemy. A leading detachment of one fourth the total strength of the advanced-guard; two flank-detachments, to act as flankers, of one eighth; and a rear detachment, acting as a rear-guard, also of one eighth,—taking, in all, one half the total strength of the advanced-guard,—is considered, under ordinary circumstances, a good distribution for the duties to be performed. All the ground within the proximity of the advanced-guard must be carefully searched by it. No invariable rule can be laid down on this subject, everything depending on the character of the country; the state of the weather; and the march being by day or night, as to the more or less dispersed order that can be adopted for examining the ground. The leading detachment, and those on the flanks, should keep in a position, with respect to each other, that will admit of prompt mutual support, and guarding against the approach of an enemy unperceived; the flank-detachments, for this purpose, keeping somewhat to the rear of the leading one. The most advanced portions of these troops should be of cavalry, unless the country be mountainous or very thickly wooded, in which cases infantry is the best arm for the duty.

FLANK-FILES.—The first men on the right and the last men on the left of a battalion, company, etc. When a battalion is drawn up three deep, its flank-files consist of three men, or, as the French call it, file and demi-file. When four deep, the flank-files are termed double files; so that a column formed from any of these alignments will have all its relative flank-files, be the depth of the formation what it may.

FLANK-MARCHES.—Marches made parallel or obliquely to the enemy's position, with a view to turning it or attacking him on the flank. Flank-marches are risky, but there are times when an army must make them and run the risk of exposing its flank in order to gain great advantages. As the greatest danger to which the column is exposed is that of being attacked in flank during the march, a strong detachment should be thrown out on the side next the enemy, to move along in a direction parallel with the column, and sufficiently near to keep up a constant communication with it. The advanced-guard usually becomes the flank-detachment on a flank-march; but it will be well, since the chances of attack are greater, to increase its strength, so that it should be able to hold its ground against any serious effort of the enemy. This detachment should be careful to occupy all defiles, and watch all the roads by which the enemy might appear, until the main body has passed. The baggage becomes, in a case like this, more of an encumbrance than usual. It may be sent to join the army by a circuitous route, at a distance from the enemy, or may move on that flank of its own column which is the safer against attack.

If possible, the march should be concealed from the enemy, keeping him in ignorance of the movement until completed. This cannot always be done, as he is on the alert to observe any movements which may be made. Under no circumstances should the flank-detachment be omitted, as by its skillful use the enemy may be kept in doubt for some time as to the particular character of the march, whether it is to the front, to the rear, or to a flank. If this detachment meets the enemy, it makes a show of resistance and develops the strength of the opposing force. In the mean time the main body moves steadily forward, and, when it has passed sufficiently far, the detachment leaves the position it had held, and retires rapidly, taking, if necessary, a direction different from that of the main body, and subsequently rejoining it by a detour. The enemy will not follow it very far, as he exposes his own flank to the troops which have already passed. When the body of troops making the flank-march is large, as a corps composed of several divisions, there should be several columns, if the nature of the country will admit of it. These columns should be in supporting distance of each other, as required in a march to the front.

Flank tactical marches were frequently made by Frederick the Great to gain a position favorable for an attack on an enemy's wing. On such occasions he formed his army in two columns of companies at full distance, so that by wheeling the companies to the right or left he formed at once a line of battle facing the enemy. Approaching the enemy with this formation, and when near him, he changed the direction of his march, making the flank-movement, protected by the advanced guard and hidden from view by some inequality of the ground. Then by a simple wheel of the companies his line of battle was formed, and was oblique to the general line occupied by the enemy. We find numerous instances of this maneuver recorded. At the battle of Lenthen he moved forward in four columns, the two interior ones being composed of infantry, and the exterior ones of cavalry. When he changed direction to make a flank-march, the four columns formed two, which by a wheel of the companies formed into two lines of battle. See *Flank-movement* and *March*.

FLANK-MOVEMENT.—This term has reference to the change of march of an army, or a portion of an army, which circumstances may necessitate, and which may occur when a battle is being fought, with the view to turning either one or both wings of the enemy, or a better position being taken up. In making a flank-movement before the enemy, it would be difficult to carry out the usual order of march as laid down for the march of an army to the *front*. Such a formation would be inconvenient to a large body of troops, if the ground or country were circumscribed or inclosed, having to march in one direction and to fight a battle in another, thus necessitating a long wheel of its columns before coming into action. To avoid this, a new order of march must be pursued.

On perfectly open ground such a movement might be accomplished by marching to a flank in order of battle; that is, in three columns formed of the two lines and the reserve, with an advanced guard protecting the flank towards the enemy. But the question is of making a march of this kind in an average broken or inclosed country, where very lengthened columns, especially of cavalry and artillery, could not without great risk offer their flank to the enemy. When a corps is moving thus to a flank, it will be of immense importance to decide whether it is to form line of battle to a front or a flank, relatively to the rest of the army and to the enemy. Thus Bülow's march to the field of Waterloo was a *flank-march;* but for the attack on the French flank, the order of march to a *front* was the proper formation for his columns.

The turning of the flank of a line of battle may be effected either by originally directing part of the army beyond that flank or by reinforcing one wing of a direct attack and deploying the added troops beyond the menaced flank during the engagement. The Prussians always seem to have operated in the latter way, engaging at the same time throughout the front. The history of the victories of the summer of 1870 is that the German corps march straight for the enemy, that the leading troops at once attack, that the rest hurry up to their support, extending and deepening the skirmishing line, and that, after a severe engagement, an extension beyond a flank renders the position untenable. See *Flank-marches.*

FLANK OF A BASTION.—In fortification, that part which unites the face to the curtain, comprehended between the angle of the curtain and that of the shoulder, and which is the principal defense of a place. Its use is to defend the curtain, the flank, and the face of the opposite bastion, as well as the passage of the ditch; and to batter the salient angles of the counterscarp and glacis, from whence the besiegers generally ruin the flanks with their artillery.

FLANK-PATROLS.—Besides the flankers proper, which constitute a portion of the movable advanced-posts, detachments of an independent character are sent out to patrol along the flanks of the main column. These should keep themselves in communication, by the suitable dispositions of vedettes, with the flankers. As the flank-patrols are frequently beyond direct supporting distance, they must adopt all the necessary dispositions against surprise of any other body marching independently; having their advanced-guard, etc., etc. These patrols keep on a level with their column; and particularly secure all lateral roads, or defiles, by which it might be suddenly attacked, until the column is beyond danger. A great activity, watchfulness, and caution should characterize this service. The officer in command of a flank-patrol must use his discretion in meeting an enemy, whether to attack him or to let him pass, if he has not himself been observed.

FLANKS OF A FRONTIER.—Certain salient points in a national boundary, strong by nature and art, and ordinarily projecting somewhat beyond the general line. The effect of these flanks is to protect the whole frontier against an enemy, as he dare not penetrate between, with the risk of their garrisons, reinforced from their own territories, attacking his rear, and cutting off communication between him and his base.

FLASH.—The flame which issues from any fire-arm or piece of ordnance on its being fired. *Flash in the pan* is an expression for the explosion of gunpowder without any communication beyond the vent.

FLASHING.—The proper incorporation of the ingredients of gunpowder is tested by *flashing;* that is, by burning a small quantity of the powder on a glass or porcelain plate. If any fine-grained powder, the quantity to be flashed is placed in a small copper measure, which is inverted over the flashing-plate. This provides for the granules being arranged in nearly the same kind of heap each time, which is important. The decomposition of the powder will be more thorough if the powder be thrown together in a small conical pile than if it be spread out in a thin layer on the plate; hence, for comparison of different powders, they should be placed on the plates as nearly as possible under the same conditions. If the powder has been thoroughly incorporated, the small charge placed on the plate will flash off when touched with a hot iron, leaving only smoke-marks on the plate. A badly incorporated powder will leave specks of undecomposed saltpeter and sulphur, forming a dirty residue. The flashing-test, though simple, requires experience and care to enable the observer to form an accurate judgment. A badly incorporated powder is easily detected; but to determine between two nearly alike, and both tolerably good, is vastly more difficult. Flashing should therefore be constantly practiced with all classes of powders, and it is advisable to keep samples of imperfectly incorporated grains to be flashed occasionally for comparison.

FLASK.—When casting a gun, the mold is formed in a case of cast-iron, called a *flask*, consisting of several pieces, each of which has flanges perforated with holes for screw-bolts and nuts, to unite the parts firmly. In casting the fifteen-inch gun, a circular flask is used, consisting of five upright sections, secured together by clamps fitting over flanges at either end of the sections; its thickness is one inch, and it is pierced with holes. The breech, or lower section, is made of sufficient length to cast the base of breech, cascabel, and square knob; the next above is twenty-five inches in length and cylindrical, being the part which embraces the cylinder of the gun; the next is the trunnion-section, fitted with trunnion-boxes having movable plates on their ends, that the trunnion-pattern may be placed and removed after the mold is finished; then there are two sections above this, the upper being about three feet longer than the required length of the gun, to admit of a "sinking-head." The entire length of the flask is twenty feet. See *Molding*

FLAT BASTION.—A bastion having its demi-gorges in the same straight line. See *Bastion*.

FLATS.—In ordnance, two vertical plane surfaces situated at equal distances from the axis of the bore. They serve to prevent the barrel from turning in the jaws of the vise when the breech-screw is taken out. See *Barrel*.

FLAW.—In casting or forging, any crack or opening which may be observed. In forging, it frequently occurs from bad welding. See *Casting*.

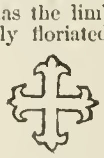
FLEAU D'ARMES.—An ancient offensive weapon; the part used for striking was armed with sharp iron spikes.

FLECHE.—In fortification, the most simple species of field-works; it is quickly and easily constructed, and therefore frequently used in the field. It usually consists of two faces forming a salient angle towards some object, from whence it cannot be approached on the prolongation of its capital. One simple rule for the construction of a flèche is to select a spot for the salient, and to throw up a breastwork on either side forming an angle of not less than 60 degrees, and allowing a distance of a yard to each file.

FLETCHER.—The name anciently applied to the man who made or repaired the military bows. He was also called *Bowyer*.

FLEUR-DE-LIS.—Authorities are undecided as to whether this celebrated emblem is derived from the white lily of the garden, or from the flag or iris, which, as generally represented, it more resembles both in form and color. "Ancient heralds," says Newton, "tell us that the Franks of old had a custom, at the proclamation of their king, to elevate him upon a shield or target, and place in his hand a reed or flag in blossom, instead of a scepter; and from thence the kings of the first and second race in France are represented with scepters in their hands like the flag with its flower, and which flowers became the armorial figures of France." However this may be, or whatever may be the value of the other legendary tales, such as that a blue banner, embroidered with golden fleur-de-lis, came down from heaven; that an angel gave it to King Clovis at his baptism, and the like; there can be little doubt that, from Clovis downwards, the kings of France bore as their arms first an indefinite number, and latterly three golden lilies on a blue field, or, as heralds would say, azure, three fleur-de-lis, or. It was Charles VI. who reduced what had hitherto been the indefinite number of fleur-de-lis to three, disposed two and one; "some conjecture upon account of the Trinity, others say to represent the three different races of the kings of France." Many English and Scotch families bear the fleur-de-lis in some portion of their shield, and generally with some reference to France.

FLEURY—FLORY.—In Heraldry, signifying that the object is adorned with fleurs-de-lis; a cross-fleury, for an example, is a cross the ends of which are in the form of fleurs-de-lis. There are several varieties in the modes of representing these crosses which has led to distinctions being made between them by heralds too trivial to be mentioned; but they are all distinguishable from the cross-potance, or potancée, incorrectly spelled patonce by English heralds. In the latter the limbs are in the form of the segments of a circle, and the foliation is a mere bud; whereas the cross-fleury has the limbs straight and the terminations distinctly floriated. Perhaps the most cele-



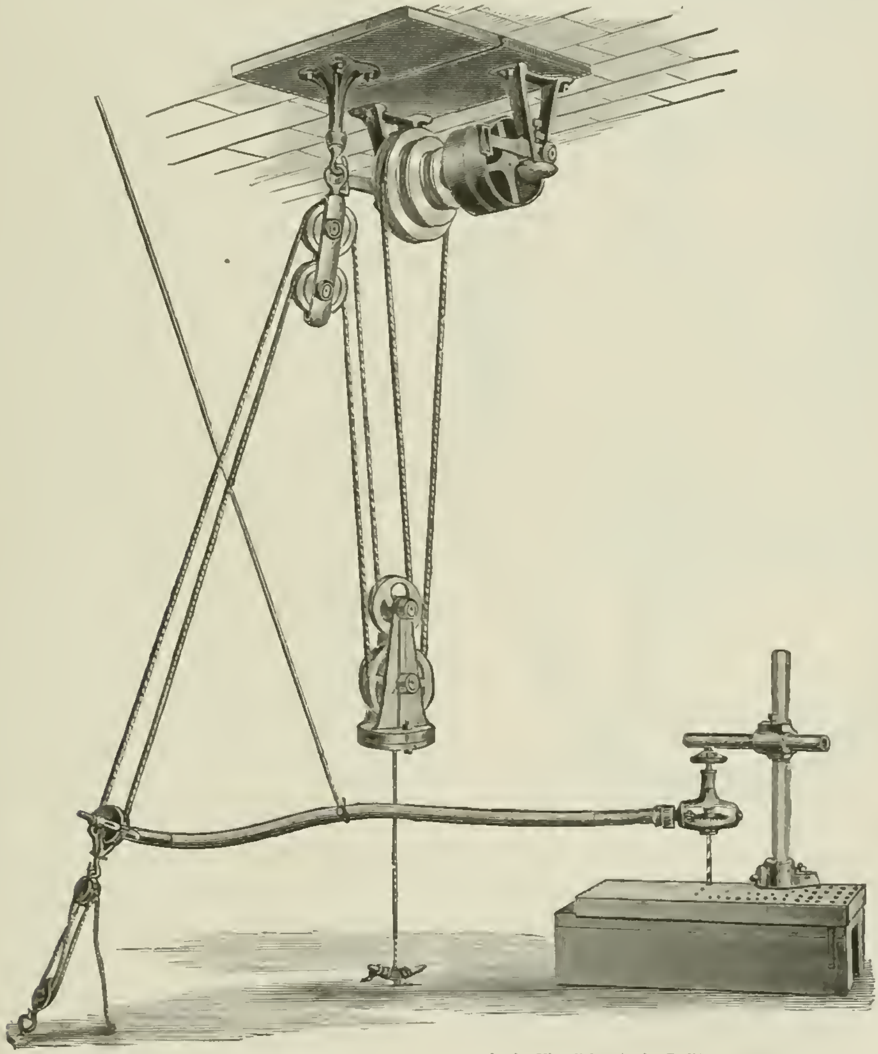
Cross-fleury.

Cross-potance.

brated instance of this bearing is in the case of the double prepuce flowery and counter-flowery gules which surrounds the red lion in the Royal Arms of Scotland, and which Charlemagne is said to have conferred on Achaius, King of Scotland, for assistance in his wars. The object, according to Nisbet, was to show that, as the lion had defended the lilies of France, these "hereafter shall continue a defense for the Scots lion, and as a badge of friendship, which has still continued." That the lilies were assumed in consequence of the intimate relation which prevailed between France and Scotland for so many generations will not be doubted; but the special occasion of the assumption may not be admitted in our day to be quite beyond the reach of skepticism, notwithstanding Nisbet's assertion that it is so fully instructed by ancient and modern writers that he need not trouble his readers with any long catalogue of them. Also written *Flowry* and *Fleurette*.

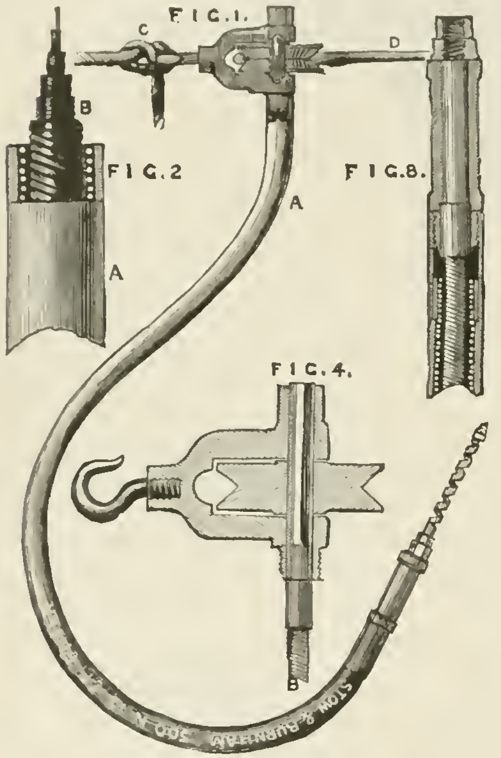
FLEXIBLE SHAFT.—An apparatus for transmitting rotary motion to any desired distance from the power source through any number of curves; thus allowing the power to be carried to the work, instead of the work to the power. The uses of the shaft in the arsenal and in engineering are almost unlimited, and as it is readily handled, easily cared for, and durable, it is rapidly becoming a staple article where work is to be done by power. The construction of the flexible shaft is peculiar to itself, and it is in this peculiar construction that its utility consists. It is made up of a series of coils of steel wire, wound hard upon each other, each alternate layer running in an opposite direction, and the number of wires in the different layers varying according to the work the shaft is adapted to; on being brought to size, about one inch at each end of the shaft is brazed solid, and to these solid ends the fittings are attached, the one to receive the tools to be operated, the other to receive the power from the pulley inclosing it, which in turn receives its power from a belt. Next a case is prepared consisting first of a single coil of steel wire, its internal diameter being a loose fit for the outside of shaft; this is covered with some flexible material, leather preferably, over which at either end a ferrule is fastened; into this ferrule at one end is screwed the hand-piece; at the opposite end the frame which carries the pulley.

The drawings show all the details of construction. Fig. 1 represents the complete shaft with the auger screwed into the end. Fig. 2 shows the manner of "laying up" the shaft, and the construction of the case. Fig. 3 is a section showing the hand-piece, shaft-case, and end-nut to which are attached the tools to be used. Fig. 4 is a section at the pulley end. Letter references: AA, shaft-case; B, sections of shaft and case; C, cord to draw pulley to any desired direction; D, driving-belt. This mode of construction insures stability, durability, and very great torsional strength; and at the same time perfect flexibility at right angles to the axis.



Round-about Transfer, combined with Countershaft, Flexible Shaft, Drill-press, etc.

In the above drawing is shown the round-about transfer, in connection with the countershaft, flexible shaft, drill-press, etc. The lower pulley takes up the slack of the driving-rope, and the swiveled pulleys at the top allow the shaft to be carried in any direction. A peculiar feature of this device, distinguishing it from all others of its class, is the fact that the rise of the lower pulleys is only one half the extension of the driving-rope, a matter of great importance in a low-studded room. With the roundabout work may be performed at varying distances from the fixed countershaft and in any desired direction. Besides metal drilling, the shaft is admirably adapted to the kindred work of tapping, reaming, and boring. The convenience of the flexible shaft is wonderfully shown in bridge-work. There are always multitudes of holes to be drilled about bridges when in construction, and the shaft will allow of many times the amount of work in the same period of time. Engineers are now beginning to specify in their specifications that all rivet-holes must be punched smaller and reamed out to a perfect circle, thus insuring a round bolt where it is intended to be. Some bridge-works are already using these shafts with marked success. In building carriages and wagons there are always great quantities of holes to be bored and drilled both in the wood and iron about the shafts and carriage-body; and this is a place where the utility of the flexible shaft is admirably shown.



Details of Flexible Shaft.

One man with a shaft and chuck with drill can do as much in an hour as has heretofore been done by hand in three or four hours. For the purpose of horse and cattle brushing the shaft is frequently used, driven by steam or other power. The brush is made in the most thorough and careful manner, and is so guarded that it cannot catch in the tail or mane of the animal. Not only is the tedious operation of cleaning horses greatly expedited by this machine, but the work is more thoroughly done than is possible in the most careful hand-grooming. The expense of finishing irregular metal dies for stamping, also the various molds, may be greatly lessened by using the shaft. Round and pear-shaped files of various sizes are used, also small emery-wheels of appropriate pattern. See *Drilling-machine.*

FLIGHT.—1. A word employed figuratively for the swift retreat of an army or any party from a victorious enemy. It is likewise applicable to missile weapons or shot; as a flight of arrows, a flight of bombs, etc. 2. In gunnery, the flight of a shot or shell is the time during which it is passing through the air from the piece to the first graze.

FLINT IMPLEMENTS AND WEAPONS.—Weapons, believed to have been used by the primitive inhabitants, have from time to time, in more or less number, been turned up by the plow and the spade, dug out from ancient graves, fortifications, and dwelling-places, or fished up from the beds of lakes and rivers, in almost every country of Europe. They do not differ, in any material respect, from the flint implements and weapons still in use among uncivilized tribes in Asia, Africa, America, and the Islands of the Pacific Ocean. The weapons of most frequent occurrence are arrow-heads, spear-points, dagger-blades, and axe-heads or celts. The more common implements are knives, chisels, rasps, wedges, and thin curved or semicircular plates, to which the name of "scrapers" has been given. There is great variety as well in the size as in the shape, even of articles of the same kind. There is equal variety in the amount of skill or labor expended in their manufacture. In some instances the flint has been roughly fashioned into something like the required form by two or three blows; in others it has been laboriously chipped into the wished-for shape, which is often one of no little elegance. In yet another class of cases, the flint, after being duly shaped, has been ground smooth, or has even received as high a polish as could be given by a modern lapidary. Examples of all the varieties of flint weapons and implements will be found in the British Museum, in the Museum of the Royal Irish Academy at Dublin, in the Museum of the Society of Antiquaries of Scotland at Edinburgh, and above all in the Museum of the Royal Society of Antiquaries at Copenhagen, which is especially rich in this class of remains.

Geological discoveries have recently invested flint implements with a new interest. At Abbeville, at Amiens, at Paris, and elsewhere on the Continent, flint weapons, fashioned by the hand of man, have been found along with remains of extinct species of the elephant, the rhinoceros, and other mammals, in undisturbed beds of those deposits of sand, gravel, and clay to which geologists have given the name of "the drift." They so far resemble the flint implements and weapons found on the surface of the earth, but are generally of a larger size, of ruder workmanship, and less varied in shape. They have been divided into three classes—round-pointed; sharp-pointed; both being chipped to a sharp edge, so as to cut or pierce only at the pointed end; and oval-shaped, with a cutting edge all round. The first and second classes vary in length from about 4 inches to 8 or 9 inches; the third class is generally about 4 or 5 inches long, but examples have been found of no more than 2 inches, and of as much as 8 or 9 inches. In no instance has a flint implement yet discovered in the drift been found either polished or ground. The French antiquary, M. Boucher de Perthes, was the first to call attention to these very interesting remains, in his *Antiquités Celtiques et Antédiluviennes.* But it has since been remembered that implements of the same kind were found in a similar position at Hoxne, in Suffolk, along with remains of some gigantic animal, in 1797, and at Gray's Inn Lane, in London, along with remains of an elephant, in 1715. Both these English examples are still preserved,—the first in the Museum of the Society of Antiquaries at London, the second in the British Museum,—and they are precisely similar in every respect to the examples more recently found in France.

To what age these remains should be assigned is a question on which Geology seems scarcely yet prepared to speak with authority. But, in the words of Mr. John Evans in his essay on "Flint Implements in the Drift," in the *Archæologia*, "thus much appears to be established beyond a doubt, that in a period of antiquity remote beyond any of which we have hitherto found traces, this portion of the globe was peopled by man; and that mankind has here witnessed some of those geological changes by which the so-called diluvial beds were deposited. Whether these were the result of some violent rush of waters, such as may have taken place when "the fountains of the great deep were broken up, and the windows of heaven were opened," or whether of a more gradual action, similar in character to some of those now in operation along the courses of brooks, streams, and rivers, may be matter of dispute. Under any circumstances, this great fact remains indisputable, that at Amiens, land which is now 160 feet above the sea, and 90 feet above the Somme, has, since the existence of man, been submerged under fresh water, and an aqueous deposit from 20 to 30 feet in thickness, a portion of which, at all events, must have subsided from tranquil water, has been formed upon it; and this, too, has taken place in a country the level of which is now stationary, and the face of which has been little altered since the days when the Gauls and the Romans constructed their sepulchers in the soil overlying the drift which contains these relics of a far earlier race of men." See *Elf-arrow-heads*.

FLINT-LOCK.—A very modern firelock, invented about 1635. It was suggested, no doubt, from the snaphaunce, and from which it only differed by the cover of the pan forming part of the steel or hammer, which retained its furrows until the eighteenth century. Before the invention of the *flint-lock*, the wheel-lock was frequently called the firelock. It does not appear to have been employed in England until 1677.

FLISSA.—An Oriental sword without a hilt or cross-guard. The handle is straight and forms with the blade a Latin cross.

FLO.—An ancient name for an arrow used in war. Seldom used at present.

FLOAT.—The wooden cover of the *sponge* or *tar-bucket* used with field-gun carriages.

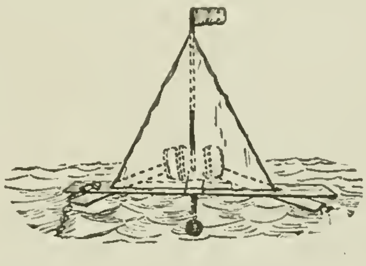
FLOATING BATTERY.—A hulk very heavily armed, made as invulnerable as possible, used in defending harbors, or in attacks on marine fortresses. The most remarkable instance of their employment was by the French and Spaniards against Gibraltar, in the memorable siege which lasted from July, 1779, to February, 1783, when ten of these vessels, carrying 212 large guns, were brought to bear on the fortress; they had sides of great thickness, and were covered with sloping roofs, to cause the shot striking them to glance off innocuously. But their solidity and strength were unavailing against the courage and adroitness of the defenders, under the gallant General Elliot, who succeeded in destroying them with red-hot cannon-balls. Steam floating batteries of iron were constructed for the war with Russia in 1854, both by the British and French governments; but, notwithstanding that they rendered good service before Kinburn, they have since been generally discarded for other than purely defensive purposes, as too cumbrous for navigation, and too suffocating from the smoke that collected between their decks during action. Indeed, vessels of this class may be regarded as having been superseded for all purposes both of attack and defense by the newer kinds of gunboats and armor-clad frigates, as well as by the turret-ships, which are among the more recent contrivances of skill in naval engineering.

FLOATING BRIDGE.—A variety of double bridge, the upper one projecting beyond the lower one, and capable of being moved forward by pulleys, used for carrying troops over narrow moats in attacking the outworks of a fort. See *Flying Bridge*.

FLOATING DERRICK.—A mechanical contrivance used for the same purposes as the crane, but recently so improved in size, strength, and mechanism as to be able not only to raise a body of 1000 tons in weight, but to transport it from one place to another. The following description of the *Great Floating Derrick*, built in 1859, will convey an idea of the powers of this machine, and of the principles upon which it works. This derrick was built by the Thames Iron Ship-building Company, at Blackwall. It consists of a flat-bottomed vessel, 270 feet long, and 90 feet across the beam, and is divided throughout into a number of water-tight compartments, which can be filled so as to counterbalance any weight on an opposite side. From the deck of this floating steam crane rises an iron tripod 80 feet high, on the top of which revolves a gigantic boom, 120 feet long, and above the boom the "king-post," a continuation of the tripod, rises to the height of 50 feet. One arm of the boom is furnished with ten fourfold blocks; the chains attached to these blocks are all passed across the king-post, brought over the other arm of the boom, and so descend to the other side of the vessel, where they are connected with two powerful steam engines, by means of which the weights are raised. This derrick is capable of being propelled by means of a series of bucket-paddle floats at the rate of 4 miles an hour. It is the invention of Mr. Bishop, an American. Derricks have been long in use in America, and have proved much more expeditious and economical than any other species of lifting-power. They are chiefly used for lifting machinery or other great weights, and for raising wrecks. See *Cranes*.

FLOATING RAVES.—A light open frame of horizontal bars, attached along the top of the sides of wagons, and sloping upwards and outwards from them. They are very convenient for supporting and securing light bulky loads.

FLOATING TARGET.—The best and most readily constructed target is composed of three stout boards twelve feet long and a foot broad, forming a triangle. A fourth board extends from one of the angles to the middle of the opposite side. The whole is fastened together with spikes, or, better, with screw-bolts. At the center of the triangle, a hole is cut in the last-mentioned board; this hole is about four inches in diameter; through it passes a pole projecting about twelve feet above and three feet below. A 10-inch shot, or equivalent weight, is secured to the lower end of the pole, and rope guys are led from the top to the angles of the platform to keep the pole upright. To these ropes are fastened triangular pieces of canvas. A bull's-eye four feet in diameter is painted on the middle of this screen, upon each side. On each side of the pole, underneath the platform, an empty water-



tight barrel is lashed to the athwart-board, and a small red flag is placed on the top of the pole. This target is suitable for even the roughest water. To hold it, under such circumstances, requires an anchor weighing not less than two hundred pounds. This is attached to the target by a chain or heavy rope, secured to one angle of the base by an eye on the under end of the bolt holding the planks together. When a single anchor is used, the chain or rope is liable to wind itself around and trip the anchor, causing it to drag. To obviate this, it is advisable to moor the target with two anchors, placed in the direction of the current. The distance of the anchors apart must depend upon the depth of the water, and should be such as to form, with the mooring-chains, about an equilateral triangle.

An empty water-tight barrel, painted some dark color, forms a good target or point at which to aim. The cask is secured in position by means of a small anchor or a kedge attached to it by a stout rope fastened to secure lashings on the cask. Instead of an anchor, any heavy body, such as a stone or bars of iron, may be used. If the current is swift, the weight should never be less than the flotation of the cask. This latter is obtained by multiplying the number of gallons contained in the cask by ten—the approximate weight of a gallon of water. A spar, similar to the spar-buoys to be seen about harbors, forms a good target and one of easy construction. When a spar or cask is used, a small flag of some bright-colored stuff, attached to the target, makes it more conspicuous and easy to aim at. The target is moored in position at the commencement of the season's firing, and is left out until the firing is completed. Its distance from the two *stations* and from the gun is determined by ordinary trigonometrical methods, or by plotting from plane-table observations. After the table is set up at its station and adjusted, the officer in charge marks upon it the line to the target, to the gun, and to the other station. These lines form the basis for the subsequent plotting of the shots. The officer at each station is accompanied by a flagman to signal to the piece whether the shots are *short* or *over*. By this means the error, for all subsequent shots, is approximately corrected.

The officer in charge of the firing attends to the loading and aiming, sees that the charges and projectiles are weighed, and that the pressure-plug (when used) is properly attached to the cartridge; also that the fuses for the shells are of the proper length. When everything is in readiness, he directs his signal-flag to be raised to inform the observers at the stations that he is about to fire. The piece is then discharged. The other officers at the battery attend to the stop-watch and telemeter. When the gun is fired, the officer at each station, sighting through the alidade, catches the point on the water where the shot strikes, or, in case of a shell, the point in the air where it explodes. He then draws a fine line to mark the direction, and gives it a number corresponding with the number of the shot. The observations thus obtained are plotted. A suitable scale is assumed (one of 1 inch to 100 yards is convenient), and the line joining the two stations is laid off on the plotting-sheet according to the scale. From this all the other lines are laid off, usually by the method of chords. The intersection of the lines to the target establishes its position, and those to the gun its position also. The distance from the gun to the target is ascertained from the scale. The lines of observation to each shot having been carefully numbered by the observers at the plane-tables, the intersection of corresponding numbers on the plot gives the striking-points of the shots or bursting-points of the shells. See *Artillery-practice* and *Target*.

FLOATING WAREHOUSES.—The danger that attends the storing of petroleum and other inflammable and explosive chemicals has led in France to the construction of warehouses, storehouses, or magazines that will float in a dock or basin, and can be moored at a distance from buildings on land. So far as concerns England, an Act of Parliament was passed in 1866 relating to the carriage and storing of dangerous substances; this law was amended and considerably extended by an Act passed in 1875, applying to gunpowder and other explosive substances (including nitro-glycerine, dynamite, gun-cotton, blasting-powders, fulminate of mercury, fire-works, percussion-caps, etc.). This Act requires such substances to be marked "gunpowder" or "explosive," and to be conveyed or stored with special precaution; it leaves much power to the Secretary of State to intervene in special cases and arrange the precise conditions. The storing of petroleum is regulated by the Act of 1871. In France, as we have said, floating warehouses have been constructed, two being finished in 1864, and others added in later years. The construction of the floating fabrics is remarkable. Each warehouse or magazine consists essentially of one hundred hollow iron cylinders, arranged in four rows of 25 each, firmly lashed or strapped together to form a kind of raft. Each cylinder, 16 feet long by 6 or 7 in diameter, has hemispherical ends, with a man-hole at one end. They are placed upright when in position, so as to be filled with petroleum, glycerine, gunpowder, or any other substance, through the man-hole. As they will hold 25 tons each, their united capacity is 2500 tons. There is a wooden covering to the top of the collected mass of cylinders, and round the sides as far down as the line of flotation, to shield the iron from fluctuations of temperature. This covering is made of thick planking, fastened to the cylinders by angle-irons which have been riveted to the latter. At the head and stern are large hawser-holes, to admit hawsers for towing and mooring the floating fabric, bringing it into and taking it out of a basin or dock, and warping it to a quay or dock wall: or, when the vessel is moored in the middle of a basin, far away from buildings, a barge may deliver or receive the dangerous cargo, and thus the vessel may be kept altogether away from quays and wharves.

FLOGGING.—Corporal punishment has existed from time immemorial in the British army and navy; formerly having been inflicted upon slight occasion, and often with barbarous severity. In deference, however, to public opinion, it has been much less resorted to during recent years, and promises almost to disappear under a regulation of 1866. A man must now be convicted of one disgraceful offense against discipline before he can be liable to flogging for the next such offense; and even after one such degradation, he may be restored to the non-liable class by a year's good conduct. The punishment of flogging, which is generally administered with a whip or a "cat" of nine tails on the bare back, cannot, under existing rules, exceed fifty lashes.

Corporal punishment is never recognized in the French army; but then the soldiers in that country are drawn by conscription from all ranks of society, and have, on an average, a higher moral tone than the British recruits, who, attracted by a bounty, volunteer usually from the lowest orders. On the other hand, the discipline in the French army, and especially during war on a foreign soil, is universally admitted to be inferior to the strict rule preserved among British troops. Soldiers and sailors being men unaccustomed to control their passions, and any breach of insubordination being fatal to the *esprit* of a force unless summarily repressed, it is considered necessary to retain the power—however rarely exercised—of inflicting the painful and humiliating punishment of flogging. The French soldier, though escaping the ignominy of personal chastisement, is governed by a code harsher than our Articles of War as actually administered; and the punishment of death, scarcely known during peace, is not unfrequently visited in France upon offenders against discipline.

The practice of flogging was long ago discontinued by the United States Government. It may be noted, however, that under the statutes of one State (Delaware) it exists as a punishment for petty crimes.

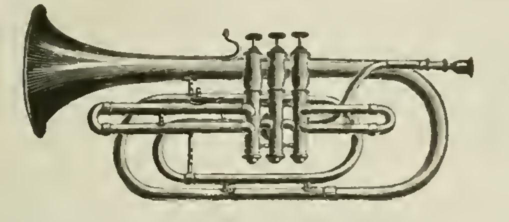
FLOODGATE.—In fortified towns, a structure composed of two or four gates, so that the besieged by opening the gates may inundate the environs so as to keep the enemy out of gun-shot.

FLOTANT.—A term employed in Heraldry to express that the object is flying in the air as, for example, a banner-flotant. See *Heraldry*.

FLOURISH.—1. To execute an irregular or fanciful strain of music, by way of ornament or prelude; as, a *flourish of trumpets*. 2. The waving or brandishing of a weapon.

FLOURISH OF TRUMPETS.—The sounding used by regiments having no bands in receiving a General Officer on parade, viz., by the trumpets or bugles sounding the "flourish."

FLUGELHORN.—The introduction of the flügelhorn into bands in this country is of comparatively recent date, though in the larger bands of Europe the very pleasing effect of this instrument is generally recognized, and is in consequence commonly used. Its key is B flat, and in size it is between the B*b* cornet and E*b* alto. It usually takes the parts given the 3d and 4th B*b* cornets, perfecting the harmony at this point where it is often weak. It can also be used with very pleasing results in certain solo parts and cadenzas, or in duos with the cornets. In fact, the flügelhorn to a band is what a French horn is to the orchestra. A band of 12 or 14 pieces should include



at least one, and of 15 to 20 pieces two of these horns. The drawing shows the E♭ alto, bell front.

FLUGELMAN.—The leader of a file; the one who stands in front of a body of soldiers, and whose motions in manual exercise they all simultaneously follow. Also written *Fugelman*.

FLUSHED.—A term frequently applied when men have been successful, as in the expression *flushed with victory*.

FLUTE.—This wind-instrument, so frequently used in military bands and so well known to the ancient Greeks, has a soft and pleasant quality of tone. It is commonly made of boxwood or ebony, but sometimes of ivory or silver. Its form is that of a taper tube, formed in four pieces, with six holes for the fingers, and with from one to fourteen keys, which cover or open other holes. The sound is produced by blowing from the mouth into the embouchure, an oval kind of hole at one side of the thick end, which is done by the lips covering a part of the hole, so that the air in its passage from the mouth is broken against the opposite edge of the hole, which causes the column of air inside the tube to vibrate. The notes of the gamut are produced by the opening or shutting of the holes by the fingers of both hands. The compass of the flute is from D to A sharp, nineteen diatonic intervals. For solo-playing, the flute with a compass from G to C is sometimes used. For orchestral purposes there are also the *tierce* flute, the octave flute, the E flat and F piccolo flute; and the highest of all, the C piccolo. Improvements on the flute have been made from time to time by Quantz, Ribock, Trommlitz, and especially by Böhm in Germany, and by Rudell and Rose in London.

FLUX.—The term given to the substances employed in the arts which cause or facilitate the reduction of a metallic ore and the fusion of the metal. *White flux* is an intimate mixture of 10 parts of dry carbonate of soda and 13 parts of dry carbonate of potash, and is mainly instrumental in withdrawing the silica or combined sand from mineral substances; *black flux* is prepared by heating in close vessels ordinary cream of tartar (bitartrate of potash), when an intimate mixture of finely divided charcoal and carbonate of potash is obtained. The latter flux, when mixed with finely divided metallic ores, and the whole raised to a high temperature in a furnace, is not only useful in removing the silica, which the carbonate of potash it contains enables it to do, but the charcoal withdraws the oxygen from the metallic oxide and causes the separation of the pure metal. Limestone is employed as the flux in the smelting of iron ores. The other fluxes are fluor spar, borax, protoxide of lead, etc. See *Iron*.

FLUXIONS.—The method of fluxions invented by Newton was intimately connected with the notion of velocity uniform and variable; and extended that notion, derived from the consideration of a moving point, to every species of magnitude and quantity. It proposed to determine in all cases the rate of increase or decrease of a magnitude or quantity whose value depends on that of another, which itself varies in value at a uniform and given rate. If x and y represent two such quantities, and $y = F(x)$ represent the law of their dependence, and if x be supposed to be the velocity with which x increases, and $\dot{y}$ that with which y changes value. Newton undertook by his method to express $\dot{y}$ in terms of $\dot{x}$ and of x, or to find $\dot{y} = F_1(x) . \dot{x}$. The quantities x and y, which in modern language we call the variables, he called *flowing* quantities or *fluents*, and $\dot{x}$, $\dot{y}$, which we should represent by dx and dy, and call differentials, he called the *fluxion* of x and y. See CALCULUS. To illustrate his notation: Suppose $y = x^n$, it may be shown that $\dot{y} = nx^{n-1}\dot{x}$. Regarding now $\dot{y}$ as a quantity depending on x and $\dot{x}$, and supposing x to increase uniformly, in which case $\dot{x}$ is constant, and $\overset{+}{(\dot{x})}$ its fluxion zero, we observe that $\dot{y}$ may have a fluxion, for it depends on the value assumed by $nx^{n-1} . \dot{x}$, when x further changes. We find $\overset{+}{(\dot{y})} = n . (n-1) . x^{n-2} . (\dot{x})^2$. Thus, second fluxion or velocity of $\dot{y}$, or $\overset{+}{(\dot{y})}$, Newton wrote $\ddot{y}$. If x had a second fluxion, or did not change uniformly, then that fluxion he wrote $\ddot{x}$. The third fluxion of y he wrote $\dddot{y}$; and so on, pointing as many points over the fluent as there are units in the order of the fluxion. For the fluent he had no special symbol. Instead of $\int nx^{n-1}\,dx = x^n$, according to the modern notation, he wrote $\underline{nx^{n-1} . \dot{x}}|$, putting the expression in an inclosure. Imagine a point to move uniformly in the direction of a fixed line, and, at the same time, to have a variable transverse motion depending upon a law which determines the character of the curve or line thus generated. The indefinite part of the curve up to any point is the *fluent*, and the exceedingly small element of the curve that is generated in the next infinitesimal, but constant, period of time is the *fluxion*. These are both variable except in the case of straight lines. Passing from the consideration of the motion of a point in a plane to that of a point in space, it is evident that the generating point will describe a straight line, or a curve of single or double curvature. Equations can be constructed formulating laws of motion which will cause the general point to trace any curve whatever, and from these equations the natures of the curves can be discovered. The science of fluents and fluxions is based upon the above principles. Any plane figure can be generated by the motion of a straight line, and any volume by the motion of a plane figure. In all cases, the portion of a plane figure or volume generated in the time t is the fluent, while that generated in the time dt is the fluxion. In practice, the method of integrals and differentials has superseded the system of fluents and fluxions, chiefly because the notation of the latter is too cumbersome.

FLY.—The length of any flag. The dimension at right angles to the staff, the other dimension being the *hoist*. The term is also applied to the outer canvas of a tent. See *Tent*.

FLYING ARMY.—A strong body of cavalry and infantry which is always in motion, both to cover its own garrisons and to keep the enemy in continual alarm. The *flying artillery* is also trained to very rapid evolutions.

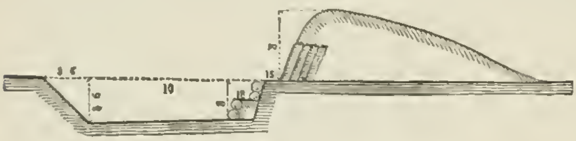
FLYING BRIDGE.—A flying bridge is an arrangement by which a stream with a good current may be crossed when, from a want of time or a deficiency of materials, it may not be possible to form a bridge. It consists of a large boat or raft firmly attached by a long cable to a mooring in the center of the stream, if the channel be straight, or on the bank, if the channel be curved. By hauling the boat or raft into proper positions, it will be driven across the stream in either direction as may be desired. The bridge is made usually of two, three, and sometimes six boats, connected together and very solidly floored over, the beams being fastened to the gunwales of the boats with iron bolts or bands, and the flooring-planks nailed down upon them. The floor is sometimes surrounded with a guard-rail. The most suitable boats are long, narrow, and deep, with their sides nearly vertical, in order to offer greater resistance to the action of the current. At the end of the rope is fixed an anchor which is moored in the channel, if this is in the middle of the stream. If the channel is not in the middle, the anchor is placed a little on one side of it towards the more distant shore. By means of the rudder, the bridge is turned in such a direction that it is struck obliquely by the current, and the force resulting from the decomposition of the action of the current makes it describe an arc of a circle around the anchor as a center, and this force acquires its maximum effect when the sides of the boats make an angle of about 55° with the direction of the current. See *Bridges* and *Trail-bridge*.

FLYING CAMP.—A camp or body of troops formed for rapid motion from one place to another.

FLYING COLORS.—Colors unfurled and left to wave in the air. Hence, *to return or come off with flying colors* is to be victorious, or to succeed in any undertaking.

FLYING PARTY.—A detachment of men employed to hover about an enemy and observe his movements.

FLYING SAP.—In all siege-operations, when the trenches have been pushed forward to within destructive range of case-shot, the construction by the simple trench has to be abandoned, and one which will afford more speedy shelter resorted to. This is effected by placing a row of ordinary gabions in juxtaposition along the direction of the trench; these being filled with the earth from the trench, the parapet is completed by throwing the remaining earth over and beyond them. This process is termed the flying sap, from the rapidity with which the work is



Section of Parallel with Flying Sap.

done. It is also executed by troops of the line, each man bringing two gabions on the ground, which he is required to fill, and also to complete the portion of the trench, in the rear of them, assigned to the relief to which he belongs. The requisite height is given to the parapet either by heaping up the earth above the top of the gabions, or by placing three ordinary fascines upon the gabions, two being in the bottom course and the other on top, and throwing up the earth at least as high as the top fascine. In positions where the earth cannot be obtained in sufficient quantity to afford a speedy cover, as in a shallow stratum of soil on rock, etc., two rows of gabions, placed in juxtaposition, may be used for the flying sap. The troops for constructing both this and the simple trench are divided into three parties or reliefs. The first digs the trench to the requisite depth and to the width of 5 feet. The second widens it 4 feet 6 inches. The third finishes what remains, giving the requisite slopes to the front and rear. See *Sap*.

FLYING-SHOT.—A shot fired at any object in motion, as a horseman, or a ship under sail, etc. The term is also applied to the marksman who fires thus.

FLYING-TORCH.—An important article of signal-equipment. This torch is attached to a long staff, and is used in night-signaling.

FLY-WHEEL.—A heavy wheel attached to machinery to equalize the movement. By its inertia it opposes any sudden acceleration of speed, and by its momentum it prevents sudden diminution of speed; in the latter case it acts as a store of power to continue the movement when the motor temporarily flags, or in passing dead-centers when the motor is inoperative. In the Cummer engine, when the fly-wheel is used, instead of having heavy weights moving back and forth with a variable velocity, there is a wheel with a heavy rim revolving continuously in the same direction with great velocity and thus storing up a large amount of energy. The work done by the steam at the commencement of a stroke, in excess of the mean work, is so small compared with the energy stored in the fly-wheel, that no great increase in velocity can take place: the fly-wheel simply absorbs the excess without a perceptible increase of speed. A similar state of things exists at the latter part of a stroke, when the steam-pressure has rapidly fallen and less work is done; the fly-wheel then yields up a part of its energy to supply the deficiency and still does not visibly retard its speed. The varying effort of the crank-pin and the varying resistance of the load are also met in the same way, and the result is to approximate very closely to a uniform tangential pressure upon the crank-pin, with only very slight variations in the velocity of the fly-wheel. Just at this point comes in the office of the governor, for the slightest change of speed is instantly met by a change in the point of cut-off and standard speed restored. But it is important to have a fly-wheel so proportioned that it does not admit of any sudden or a great change of speed. If the rim is not heavy enough, any slight change of pressure or load causes considerable change of speed, and when the governor acts to correct this there is caused a variation in the other direction; thus with a sensitive governor and a light fly-wheel there is a continual and quite unnecessary fluctuation of speed. This does not occur with such a weight of rim as the fly-wheels of the Cummer engine have; with them the permissible variation from standard speed is very small, and the governor is depended upon for the rest of the regulation.

As a matter of interest in connection with fly-wheels, we have made a diagram which shows the variations of power, above and below the mean work done in a revolution, with a steam-pressure of 90 lbs. and a cut-off of $\frac{1}{5}$ stroke. The mode of constructing this diagram is very simple and it may be briefly explained:

We constructed an ideal diagram, such as Fig. 1, for steam at 90 lbs., cut-off at $\frac{1}{5}$ stroke, and then expanded to the end. The length of the diagram representing the stroke, we may construct a semicircle upon this line and divide the half-circumference into equal parts, representing successive positions of the crank; if the connecting-rod be infinitely long, lines drawn from these points, at right angles to the base-line, will give the corresponding positions of the piston, and, being ordinates of an indicator-diagram, will show by their length the pressure upon the piston for each of these positions of the crank. These

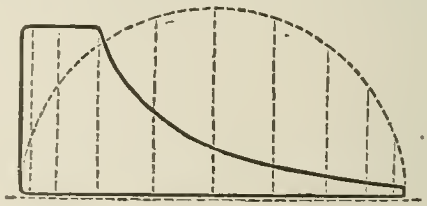


Fig. 1.

pressures, however, are not just those which propel the crank; it is the tangential pressures upon the crank which we desire to have; these are different for each angle of the crank with the line of centers; and, since in practice the connecting-rod has a definite length, its modifying influence must be allowed for. We made then a table of tangential pressures for forty equal divisions of the circle, supposing the radius to represent a pressure of one pound per square inch on the piston, and allowed for a connecting-rod of six cranks' length. Then from the diagram were found the effective steam-pressures corresponding to each crank-position, which, multiplied by the tangential crank-pressures for one pound pressure on the piston, gives the tangential pressure for each division, with 90 lbs. initial steam-pressure, and the various effective pressures for successive points as taken from the diagram. Referring to Fig. 2, the inner circle has a diameter equal to the length of the diagram, and it is subdivided into a number of equal parts, and radial lines are drawn extending beyond the cir-

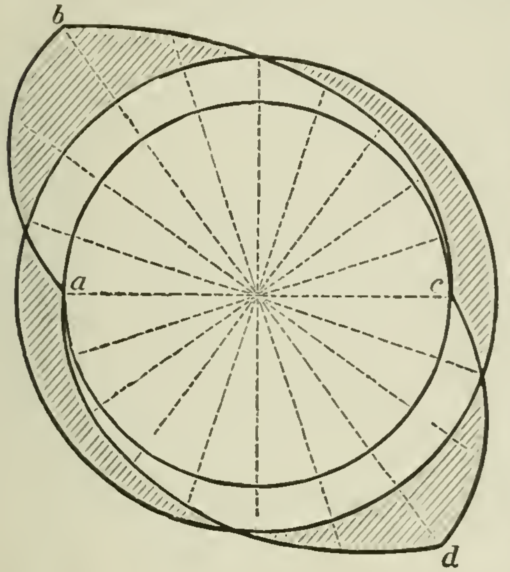

Fig. 2.

cle; upon each line is laid off the corresponding tangential pressure, and the extremities joined by a line makes the curve *a b c*, starting from *a*, where the pressure is 0, and ending at *c*, where the pressure is also 0. The return-stroke gives a corresonding curve, *c d a*. We now find the mean tangential pressure, which is, of course, the average of all these other pressures, and represent it by the outer circle. It will be seen that the area inclosed between the two circles represents the work done in a revolution; also that the sum of the areas included between the two curves *a b c*, *c d a* and the inner circle represents the same work. These two curves cross the circle of mean pressure, a part of the curve being above and a part below the line; for that part of a revolution where the curve extends above the circle the work is in excess, and for that portion where the curve goes below there is a deficiency of work done. Two phases of a revolution show an excess, and two phases a deficiency, and the excess balances the deficiency for an entire revolution, as we find on calculating the areas. Comparing the whole excess or deficiency with the work done in a revolution, which is represented by the mean pressure upon the crank-pin, exerted through 360°, or the complete circle, we find a variation of 37.5 per cent for a whole revolution. If we take the greatest area, which is the excess during the first quadrant, and compare it with the work for a stroke, or a half-revolution, we will have a variation of 45.4 per cent. See *Steam-engine*.

FOCUS OF EXPLOSION.—The center of the chamber of a mine. See *Crater* and *Mines*.

FOCUS OF IGNITION.—The point at which the powder-hoses or the *saucissons* are brought together when several mines are to be fired simultaneously.

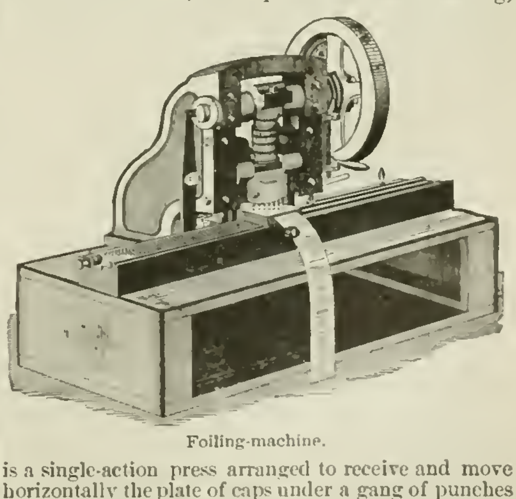
FODDER.—The food collected by man for the use of the domestic herbivorous quadrupeds. In English, the term is commonly restricted to dried herbage, as hay and straw; but in other languages it is more comprehensive, and includes all the food of stock except what they gather for themselves in the field. The principal part of the food of all the domestic herbivora is furnished by grasses, almost all of which are eaten by them when fresh and green. Besides the supplies which they receive of all the kinds of corn cultivated for human food, they are also, to a considerable extent, dependent on the *straw* or dried herbage of the corn-plants for their winter provender; and that of many other grasses, cultivated on this account alone, is converted into *hay* for their use. Hay, being cut and rapidly dried whilst the plant is still full of sap, contains more nutritious matter than the ripened straw of the cereals. The most important fodder-grass is rye-grass, next to which must be ranked timothy-grass; but all the meadow-grasses and larger pasture-grasses also contribute to the supply of hay. Next to the grasses must be ranked different kinds of *leguminosæ*, affording food for stock in their seeds—as beans, peas, lentils, lupines, etc.—and in their herbage, on account of which many of them are cultivated, as clover, medick, melilot, vetch, tare, sainfoin, etc., of some of which there are numerous species. Some of these also often enter pretty largely into the composition of hay, being cut and dried with the grasses along with which they have been sown; which is the case also with some plants of other orders, as the ribwort plantain, etc. Some of the *cruciferæ* are cultivated to a considerable extent as forage-plants, cattle being fed on their green herbage, although they are not suitable for drying as fodder. In portions of the world, stock are not unfrequently fed on the leaves of trees, as in the Himalayas, where the leaves of different species of *aralia*, *grewia*, elm and oak, are chiefly employed for this purpose, and are collected, dried, and stacked for winter fodder. See *Forage*.

FOE.—An enemy in war; a national enemy; a hostile army; an adversary. Also written *Foeman* and *Fone*, but the latter is now obsolete.

FOGEY.—1. A term sometimes applied to an invalid soldier or sailor. 2. The common expression for extra pay for long service.

FOIL.—1. A thin bar of elastic steel, mounted as a rapier, but without a point, and additionally blunted at the end by the presence of a button covered with leather. See *Fencing*. 2. A general name for thin metal intermediate in thickness between *leaf-metal*, such as gold, silver, and copper leaf, and *sheet-metal*. There are two distinct kinds of foil in common use—the tin-foil used for silvering and for the conducting coatings of electrical apparatus; and the bright foils employed by the jewelers for backing real or artificial gems, and thereby increasing their luster or modifying their color.

FOILING-MACHINE.—A machine employed in the fabrication of cartridge-primers. The one used at Frankford Arsenal, and represented in the drawing,



Foiling-machine.

is a single-action press arranged to receive and move horizontally the plate of caps under a gang of punches and dies. The strip of foil is fed between these tools, and by them cut into disks. The punches press the disks through the dies into the caps, and the ends of the punches, being concave, press the edges of the disks around the charges against the bottoms of the caps, and at the same time the punch gives the charge a uniform conical shape, that its height may permit the insertion of the anvil far enough into the cap to prevent any premature explosion in this operation and that of inserting the completed primer in the pocket of the shell, while leaving no unnecessary space between the anvil and the apex of the charge. See *Cartridge-primer* and *Center-primed Metallic-case Cartridge*.

FOISSONNEMENT.—A term used in fortification to signify the increase in bulk of earth after its excavation. This increase varies from one eighth to one twelfth generally. For all ordinary sand it is one twentieth.

FOLDING-BOAT.—A boat having a jointed framework covered with canvas, used in campaigning and by travelers.

FOLLOW-BOARD.—A board beneath the pattern, in the foundry, and on which the pattern lies while the loam is being rammed. See *Bronze Guns*.

FOLLOWER-WEIGHT.—A weight employed in the *feed-drums* of certain machine-guns to force the cartridges downward towards the barrels when firing. See *Gatling Gun* and *Feed-drum*.

FOLLOW UP.—To pursue with an additional vigor some advantage which has already been gained.

FOOD.—Although very nearly sixty elementary substances are known to chemists, only a comparatively small number of these take part in the formation of man and other animals; and it is only this small number of constituents which are essential elements of our food. These elements are carbon, hydrogen, nitrogen, oxygen, phosphorus, sulphur, chlorine, sodium, potassium, calcium, magnesium, iron, and fluorine.

Carbon, hydrogen, nitrogen, and oxygen are supplied to the system by the albuminous group of alimentary principles, viz., albumen, fibrine, and caseine, which occur both in the animal and vegetable kingdoms, and the gluten contained in vegetables. Animal flesh, eggs, milk, corn, and many other vegetable products contain one or more of these principles. The gelatinous group also introduces the same elements into the system when such substances as preparations of isinglass, calves' feet, etc., are taken as food. Carbon, hydrogen, and oxygen are abundantly introduced into the system in the form of sugar, starch (which occurs in large quantity in the cereal grains, leguminous seeds, roots, tubers, etc., used as food), and organic acids (which, as citric, malic, tartaric acid, etc., occur in numerous vegetables employed as food). Carbon, with a little hydrogen and oxygen, occurs abundantly in the oleaginous group of alimentary principles, as, for instance, in all the fat, suet, butter, and oil that we eat; in the oily seeds, as nuts, walnuts, cocoa-nuts, etc.; and in fatty foods, as liver, brain, etc. Phosphorus is supplied to us by the flesh, blood, and bones used as food (the flesh of fishes is especially rich in phosphoric matter), and in the form of various phosphates it is a constituent of many of the vegetables used as food. The system derives its sulphur from the fibrine of flesh, the albumen of eggs, and the caseine of milk, from the vegetable fibrine of corn, etc., from the vegetable albumen of turnips, cauliflowers, asparagus, etc., and from the vegetable caseine of pease and beans. Most of the culinary vegetables contain it, especially the *cruciferæ*. Chlorine and sodium, in the form of chloride of sodium, are more or less abundantly contained in all varieties of animal food, and are taken separately as common salt. Potassium is a constituent of both animal and vegetable food; it occurs in considerable quantity in milk, and in the juice that permeates animal flesh; and most inland plants contain it. We derive the calcium of our system from flesh, bones, eggs, milk, etc. (all of which contain salts of lime); most vegetables also contain lime-salts; and another source of our calcium is common water, which usually contains both bicarbonate and sulphate of lime. Magnesium in small quantity is generally found in those foods that contain calcium. Iron is a constituent of the blood found in meat; and it occurs in smaller quantity in milk, in the yolk of egg, and in traces in most vegetable foods. Fluorine occurs in minute quantity in the bones and teeth. This small quantity is accounted for by the traces of fluorine found by Dr. George Wilson in milk, blood, etc.

These simple bodies are not, however, capable of being assimilated and converted into tissue; they must be previously combined, and this combination is primarily conducted by the vegetable kingdom. The number of combined elements varies: thus water contains only 2; sugar, starch, fat, and many organic acids contain 3; caseine contains 5; and fibrine and albumen contain 6.

It would be impossible, and it is quite unnecessary, to mention in this article the different animals and plants that are used as food by different nations. The subject is, however, an interesting one, and those who desire to study it may be referred to Moleschott's *Physiologie der Nahrungsmittel* (1850), and especially to Reich's *Nahrungs- und Genussmittelkunde* (1860-61), which is the most learned and elaborate work on the subject in any language. See *Dietary*.

FOOT.—1. The most common unit of lineal measure all over the world. It has been evidently taken originally from the length of the human foot, and as that varies in length, so does the measure; each country, and at one time each town, having a foot of its own. The three foot-measures that occur most frequently are the Paris foot, or *pied de roi*, the (German) Rhenish foot, and the English. Compared with the French *meter* (= 3.28090 feet English), they stand thus:

		Meters.			Inches.
English foot	=	0.30479	Paris foot	=	12.78912
Paris "	=	0.32484	Rhenish foot	=	12.35652
Rhenish "	=	0.31385			

In round numbers, 46 French feet = 49 English feet, 34 Rhenish or German feet = 35 English, and 57 French feet = 59 Rhenish. The Russian foot is equal to the English. Almost every German State has or had a different foot. The Rhenish foot is that used in Prussia. The longest foot occurring is the old Turin foot = 20 inches English. Many local feet are only about 10 inches. The foot has almost uniformly been divided into 12 inches; the inch into 12 lines, often into tenths. The Frence *pied usuel* is the third part of the meter.

2. A term often applied to foot soldiers. The infantry is usually designated as the *foot*, in distinction from the cavalry.

FOOT-ARTILLERY.—Artillery soldiers serving on foot. The name is also applied to heavy artillery.

FOOT BOARDS.—The transverse boards on the front of a limber, on which the cannoneers rest their feet when mounted.

FOOT-FIGHT.—A conflict by persons on foot; in opposition to a fight when mounted or on horseback.

FOOT-GUARDS.—The flower of the British infantry, and the garrison ordinarily of the metropolis, comprise three regiments, the Grenadier, Coldstream, and Scots Fusilier Guards, in all 7 battalions and 6307 officers and men. See *Guards*.

FOOT-LEVEL.—A form of level used by gunners in giving any proposed angle of elevation to a piece of ordnance.

FOOT-POUND.—The unit by which the *work done* by a force is estimated; thus (taking 1 lb. and 1 foot as the units of weight and distance), if 1 lb. be raised through 1 foot, the *work done* is equal to 1 foot-pound; if 10 lbs. be raised 9 feet, the *work done* is 90 foot-pounds; and generally, if W represent the *work done*, P the *weight in pounds*, and h the *height in feet*, then W (in foot pounds) = Ph.

FOOT-TON.—In England the power of modern ordnance is estimated by the energy of the shot in foot-tons, divided by the number of inches in the shot's circumference. The expression for the energy is

$E = \frac{WV^2}{2\pi r . g}$, in which W is the weight of the shot in tons, V is the velocity, $2\pi r$ the circumference of the shot in inches, and g the force of gravity. $\frac{WV^2}{g}$ is the living force of the shot, and is equal to twice the quantity of work it is capable of doing.

FORAGE.—1. To collect supplies both for man and stock, from an enemy by force, and from friends by impressment. In the latter case receipts are given and the claims are paid ultimately.

2. The hay, corn, fodder, oats, etc., required for the subsistence of the animals in an army. It is of two kinds, green and dry; the former consists of green grass, tares, vetches, etc.; the latter of oats, hay, and sometimes of corn, fodder, barley, etc., according to circumstances and the country in which the animals may be serving. In India the daily food given to horses consists of grain and grass. Generally 4 seers or 8 pounds per horse is given of the former during the warm season, and 5 seers throughout the cold weather and when on the march. Grass, about 30 pounds daily, is provided by grass-cutters, of whom there is usually one to every two animals. On the march, should it be difficult to obtain grass, a requisition is made on the Civil Authorities to collect it at any named place. The forage for bullocks in India consists of 6 pounds of grain and 14 pounds of chopped straw, called *bhoosa.* Camels feed on the leaves of the pepul-tree. Elephants are fed on wheaten cakes mixed with molasses, called in India *gour.* The daily ration is from 15 to 30 pounds according to the size of the animal. The green food consists of sugar-cane or green leaves of different trees. Where troops are together, in England, the provision of forage devolves on the Commissariat: Officers of the Staff, etc., who are entitled to horses, but whose duties are at stations where bodies of horse are not collected, receive a money allowance, in lieu of forage in kind, varying according to the place and price of provender, but usually about 1*s.* 10*d.* to 2*s.* per horse per day. When a soldier is *en route* away from his regiment, the innkeeper with whom he stops is bound, under the Mutiny Act, to provide his horse with the specified ration of forage—viz., 10 pounds oats, 12 pounds hay, and 8 pounds straw, for the payment of 1*s.* 9*d.* a day, which must also include stabling. The daily ration in the United States army is for each horse 14 pounds hay and 12 pounds oats, barley, or corn. For a mule the same amount of hay with 9 pounds grain. Leaves of Indian corn are used in default of hay. The consumption of forage during active army operations is enormous, and the weight is four and a half times as much as that of all other subsistence supplies. During the War of the Rebellion there were issued from the depot of Washington 4,500,000 bushels of corn, 29,000,000 bushels of oats, and 490,000 tons of hay. Partial reports of the Quartermaster General show issnes of forage during the war as follows:

22,816,271 bushels of corn, costing	$29,879,314
78,663,799 bushels of oats, costing	76,362,026
1,518,621 tons of hay, costing	48,595,872
Total	$154,837,212

The weight of these supplies in pounds was—

Corn	1,277,711,176
Oats	2,517,241,568
Hay	3,037,242,000

—making a total of 6,832,194,744 pounds: numbers interesting as showing the magnitude of the operations necessary to provide and distribute these few items of the expenses of war.

The endurance and capabilities of the stock in the field will depend upon the proper supply of nutritious forage, and it is incumbent upon the soldier to instruct himself as to the properties and chemical constituencies of the different articles of forage.

Oats contain about three fourths their weight of nutritious matter. When good they should be dry, sweet, heavy, and rattle like shot. They are most nutritious when about one year old. New oats are difficult to digest, and often occasion colic and staggers. All such, or those that are wet and musty, should be kiln-dried before feeding. Oats possess an invigorating principle not found in any other grain. Oat-meal, in the form of gruel, constitutes one of the most satisfactory articles of food for the sick and tired horse. Hay should be one year old, if procurable, when fed. New hay acts as a purgative. Old hay becomes dry, tasteless, innutritive, and often mow-burnt, in which condition it becomes really poisonous. Horses fed on such soon become languid, hide-bound, worthless, and often victims of diabetes. Hay must not be fed in too large quantities. Many diseases of the horse are the results of over-feeding with hay. Horses are prone to eat more than they should, hence it is necessary to add grain containing more nutriment in a smaller compass. Barley contains about nine tenths its weight of nutritious matter, but is not so good as oats as an article of food. Animals fed upon it are subject to mange, surfeit, and inflammatory complaints. Barley-straw induces diseases of the skin. Wheat contains more nutritious matter than barley and more gluten than any other grain. It should be fed in small quantities, or colic and fomentation will result. It is difficult of digestion, and the horse fed on it should have but little hay and water soon afterwards. Under certain conditions the addition of other articles to the forage ration is very beneficial. Peas and beans, in small quantities and about one year old, are excellent articles of food for horses. They should be well crushed before feeding, and generally fed with hay. If fed alone they might produce the meagrims or staggers. Carrots when sliced and mixed with grain make a splendid provender for the horse, and are found to be very beneficial in all breathing and skin disorders, coughs, and broken wind. They should be fed in small quantities, as they are slightly laxative and diuretic at first. Potatoes possess great virtue as an article of horse-food. If they are slightly steamed before feeding, horses will prefer them to oats. If they are mixed with other provender, there is a great saving in expense and an increased capability for work. One acre of potatoes is equivalent to four acres of hay.

FORAGE-CAP.—The small, low cap worn by officers and enlisted men when not in full dress. In the United States army the following patterns are worn: *For General Officers.*—Of dark blue cloth, chasseur pattern, with black velvet band and badge in front; cap-cord of gold lace. *For all other Commissioned Officers.*—Of dark blue cloth, chasseur pattern, with badge of corps or regiment in front, and top of badge

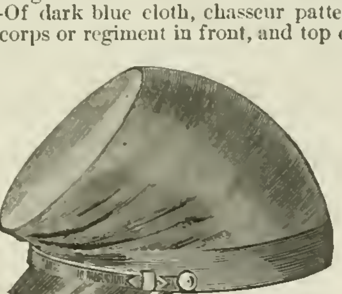


Fig. 1.

to be even with top of cap; cap-cord of gold lace. *For all Enlisted Men.*—Of plain blue cloth, same pattern as for officers, with badge of corps or letter of company of yellow metal, worn in front as for officers. The following are the authorized forage-cap badges for officers and men: *For General Officers.*—A gold-embroidered wreath on dark blue cloth ground, encircling the letters U. S. in silver, old English characters. *For Officers of the Adjutant General's Department.*—A solid shield of silver bearing thirteen stars, according to pattern in the Adjutant General's Office. *For Officers of the Engineers.*—A gold-embroidered wreath of laurel and palm encircling a silver turreted castle on dark blue cloth ground. *For Officers of Ordnance.*—A gold-embroidered shell and flame on a dark blue cloth ground. *For Officers of the Signal Corps.*—According to the pattern deposited in the office of the Chief Signal Officer.—*For Officers of the other Staff Corps.*—The same as prescribed for General Officers. *For Officers of Cavalry.*—Two gold-embroidered sabers, crossed, edges upward, on dark blue cloth ground, with the number of the regiment in silver in the upper angle. *For Officers of Artillery.*—Two gold-embroidered cannons, crossed, on dark blue cloth ground, with the number of the regiment in silver at the intersection of the cross-cannon. *For Officers of Infantry.*—Two gold-embroidered rifles without bayonets, barrels upward, on dark blue cloth ground, with the number of the regiment in silver in the upper angle. *For Light Artillery and Cavalry Soldiers.*—

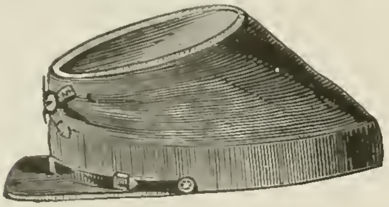

Fig. 2.

The numbers of their regiments in the upper, and the letters of their companies in the lower, angles of the badges of their respective arms upon the forage-caps. *For Ordnance Sergeants and Soldiers.*—The "shell and flame" on the dress and forage caps. *For Hospital Stewards.*—The letters "U. S." in white metal, inclosed by wreath, on dress and forage caps. *For Commissary Sergeants.*—Crescent in white metal, the points in a vertical line, on the dress and forage caps. *For Engineers.*—The castle, with letter of company above it, on dress and forage caps. *For Artillery.*—The crossed cannons, with number of the regiment in upper, and letter of company in lower, angles, on dress and forage caps. *For Infantry.*—The crossed rifles, with the numbers of regiment and the letters of company placed as for artillery, upon dress and forage caps. *For Field and Band Musicians.*—Bugle, with numbers of regiment in the center, and the letters of the company above the bugle. See Figs. 1 and 2.

FORAGE-GUARD.—A detachment sent out to secure foragers. They are posted at all places where either the enemy's party may come to disturb the foragers, or where they may be spread too near the enemy, so as to be in danger of being taken. This guard consists both of horse and foot, who must remain on their posts till the foragers are all off the ground.

FORAGE-MASTER.—A person in charge of the forage; his duties being to provide the necessary forage and its means of transportation. The Quartermaster General is authorized to employ from time to time as many Forage-masters as he may deem necessary for the service, not exceeding twenty. See *Wagon-master.*

FORAGING.—The collection of forage or other supplies systematically in towns or villages, or going with an escort to cut nourishment for horses in the fields. Such operations frequently lead to engagements with the enemy. Foraging-parties are furnished with reaping-hooks and cords. The men promptly dismount, make bundles with which they load their horses, and are prepared for anything that may follow. The word *foraging* is sometimes inaccurately used for marauding. When foraging is effected in villages, it is best not to take the party into the village, but to send for the chief persons and stipulate with them that the inhabitants shall bring the required forage and other stores out to the troops. If the inhabitants do not promptly comply with this moderate command, it is necessary to take the troops into the village. In this event all possible means must be taken to prevent disorder, as for instance: 1. A certain number of houses are assigned to each company, so that the Commander of the detachment may hold each company responsible for the disorders committed within its limits. 2. Guards are posted and patrols sent out, who arrest any foragers guilty of disorder. 3. If the form of the village permits, a part of the detachment remains at the center to pack the horses and load the wagons as fast as the other men bring the forage from the houses. In places where an attack may be expected, the foraging is conducted as follows: Either fatigue-parties are sent with wagons, or parties of cavalry with their own horses; in both cases a special escort is added for the protection of the foragers. In all cases the strength of the escort depends upon the degree of danger, the space over which the foraging is to extend, and the distance from the enemy. During the march of foragers to and from the foraging-ground, if they consist of a fatigue-party with wagons, an escort is added, which acts in conformity with the rules for escorting convoys. If the foragers consist only of cavalry with their own horses, then on the outward march they move in one body, observing the precautions prescribed for movements near the enemy; on the return-march, if the horses of the foragers are packed and led, the detachment acting as escort should not pack more than forty pounds on their horses, so that the load may not prevent them from acting against the enemy. Sometimes the escort, or a part of it, may be sent out early to the foraging-ground to take measures for the security of the foragers before they arrive. For the safety of the foragers when at their work, the escort is divided into two or three parts, according to circumstances; one part places a chain of outposts and sends out patrols to guard the whole ground; another furnishes the supports of the outposts, and if there are infantry or mounted rifles with it they occupy the points which cover the approaches; the third part is placed in reserve near the center of the ground, that it may easily reach any point attacked. If the enemy attacks while the foraging is going on, the escort should go to meet him or defend itself in position, endeavoring to stop him until the foragers have finished their work and are drawn out on the road for their return-march; then the escort commences its retreat, acting as a rear-guard, and endeavoring to keep the enemy as far from the foragers as possible. If it is impossible to hold the enemy in check long enough to finish the work, they should at least send forward and protect all the foragers who have packed their horses or loaded their wagons; the rest join the escort. If there is a probability of driving off the enemy by uniting all the foragers to the escort, it is best to abandon the forage already packed, and to begin foraging anew after having repulsed the enemy. It is permitted to abandon the forage entirely only in extreme urgency, when there is absolutely no other way of saving the foragers. If the enemy is repulsed, we must not be induced to pursue him except far enough to prevent a renewal of the attack, but must endeavor to complete the foraging. The foraging must not be extended over any ground not guarded by the escort. If the escort is too weak to cover the whole space designated for foraging, the ground is divided into parts, and the foraging effected in the different portions successively. If the foraging-ground is at a considerable distance from the camp, it will be a proper precaution to post a special detachment in support half way. Foraging in places occupied by the enemy is undertaken only upon the entire exhaustion of the ground occupied by our own troops. Such foraging is covered by offensive operations, so that, having driven in the enemy's advanced troops or other parties, we may rapidly seize all the supplies to be found in the vicinity. This is called *forced foraging.* The strength and composition of a detachment for forced foraging must be such that it can overwhelm the enemy's troops, and remain long enough in position to enable the accompanying detachment of foragers to complete their work and retreat out of danger. The main conditions of success in such an enterprise are suddenness, rapidity, and determination in the attack, promptness in the work of the foragers, and tenacity in holding the position taken from the enemy as long as necessary. Success will be greatly facilitated by partial attacks made upon different points of the enemy's position while the foraging is going on. Attacks upon foragers should be sudden and rapid, in order, by not giving the escort time to defend the points attacked, to produce confusion among the foragers and thus prevent them from working. The approach of the attacking party should be concealed, rapid, and compact; that is, it should not send out parties to any great distance in front or on the flanks, and, as a general rule, should not divide its force prematurely, but only the moment before the attack. The force of a detachment sent to attack foragers depends chiefly upon the object of the attack—that is, whether it is designed to capture the foragers, or only to prevent them from foraging by alarming them, or to prevent them from carrying off forage already packed. It is in all cases advantageous to begin with several simultaneous false attacks by small parties, to perplex the enemy and oblige him to divide the escort; then to direct the main party of the detachment upon the principal point of the enemy's arrangements, overthrow his weakened escort, and penetrate to the road of retreat, so as either to cut off and destroy a part of the escort and foragers, or to force them to abandon their work and fly, by threatening to cut them off. If from the disproportion of force it is impossible to prevent the foraging entirely, the attacking party confines itself to delaying the work; its operations, therefore, should consist in partial attacks upon several points, in order to alarm and disperse the foragers by breaking through the outposts at several points. Upon meeting any considerable force of the enemy these attacking parties should at once retreat, and renew the attack in a different place. In such operations a portion of the attacking detachment should be kept together and held in reserve, as a support and rallying point for the small parties. If they do not succeed in preventing the foraging, they may try to attack the foragers on the return-march; observing in this case the rules laid down for attacks upon convoys. See *Convoy*.

FORCAT.—A rest for the musket, used in very ancient times. It is now obsolete.

FORCE.—Until we know what matter is, if there be matter, in the ordinary sense of the word, we cannot hope to have any idea of the absolute nature of force. Any speculations on the subject could only lead us into a train of hypotheses entirely metaphysical, since utterly beyond the present powers of experimental science. If we content ourselves with a definition of force based on experience, such a definition will say nothing of its nature, but will confine itself to the effects which are said to be due to force, and in the present state of our knowledge it is almost preposterous to aim at more. Our first ideas of force are evidently derived from the exertion required to roll, or lift, bend, or compress, etc., some mass of matter; and it is easy to see that in all such cases where muscular contraction is employed, matter is moved, or tends to move. Force, then, we may say generally, is *any cause which produces, or tends to produce, a change in a body's state of rest or motion.* The amount or magnitude of a force may be measured in one of two ways: 1. By the pressure it can produce or the weight it can support; 2. By the amount of motion it can produce in a given time. These are called respectively the statical and dynamical measures of force. The latter is, as it stands, somewhat ambiguous. What shall we take as the quantity of motion produced? Does it depend merely on the velocity produced, or does it take account of the amount of matter to which that velocity is given? Again, is it proportional to the velocity itself, or to its square? This last question was very fiercely discussed between Leibnitz, Huyghens, Euler Maclaurin, the Bernouillis, etc.; Leibnitz being, as usual with him in physical questions, on the wrong side. Newton, to whom we owe the third law of motion, had long before given the true measure of a force in terms of the motion produced. This law is an experimental result—that when pressure produces motion, the *momentum* produced is proportional to the pressure, and can be made (numerically) equal to it by employing proper units. Hence, momentum is the true dynamical measure of force, which, therefore, is proportional to the *first* power only of the velocity produced. What is properly measured in terms of the *square* of the velocity we shall presently see.

It is obvious that in order to produce any effect at all, or to do WORK, as it is technically called, a force must produce *motion*, i.e., must move its point of application. A weight laid on a table produces no effect whatever unless the table yields to the pressure; i.e., unless that weight descends, be it ever so little. We do no work, however much we may fatigue ourselves, if we try to lift a ton from the floor; if it be a hundred-weight only, we may lift it a few feet, and then we shall have done work—and it is evident that the latter may be measured as so many pounds raised so many feet—introducing a novel unit, the *foot-pound*, which is of great importance, as we shall shortly see, in modern physics. This is evidently, however, a statical measure of work, since no account is taken of velocity. Have we then for work, as we had for force, a *dynamical* measure? Let us take a simple case, where the mathematical investigation is comparatively very easy, and we shall find we have. We know that if a particle be moving along a line (straight or not) and the distance moved (in the time t) along the line from the point where its motion commenced be called s, its velocity is $v = \frac{ds}{dt}$. Also we know that the force acting on it (in the direction of its motion) is to be measured by the increase of momentum in a given time—this gives (just as the last equation was obtained) $F = m\frac{dv}{dt}$. From these two equations, we have, immediately, $mvdv = Fds$, or, as the rudiments of the differential calculus give at once, $\frac{mv^2}{2} = \int_0^s Fds = F.s$ if the force be uniform. The quantity on the right-hand side is the sum of the products of each value of F by the corresponding space ds through which the particle moved under its action. It is therefore the whole work done by the force. On the left hand we find half the product of the mass, and the square of the velocity it has acquired; in other words, the vis-viva. Hence, in this case, the vis-viva acquired *equals* the amount of work expended by the force.

It appears from a general demonstration (founded on the experimental laws of motion, and therefore true, if they are), but which is not suited to the present work, that if, in any system of bodies, each be made up of particles or atoms, and if the forces these mutually exert be in the line joining each two, and depend merely on the distance between them, then we can express the required proposition in the following form: *Any change of vis-viva in the system corresponds to an equal amount of work gained or lost by the attractions of the particles on each other.* What is spent, then, in work is stored up in vis-viva; and conversely, the system, by losing some of its vis-viva, will recover so much work-producing power. If we call the former, as is now generally done, *kinetic*, and the latter *potential*, *energy*, we may express the above by saying, that in any system of bodies where the before-mentioned restrictions are complied with, *the sum of the kinetic and potential energies cannot be altered by the mutual action of the bodies.* The most simple and evident illustrations of this proposition are to be found in the case of the force known as gravitation. The potential energy of a mass on the earth's surface is zero, because, not being able to descend, it has, in common language, no work-producing power. If it be raised above the surface, and then dropped, it is easy to see that the work expended in raising it will be exactly recovered as vis-viva after its fall. For a mass falling through a space h to the earth acquires a velocity v, such that $v^2 = 2gh$; or if m be the mass, $\frac{mv^2}{2} = mg.h$. The left-hand side gives the vis-viva acquired by the fall; the right is the product of the weight (mg) and the height fallen through —or is the work required to elevate the mass to its original altitude. Hence we may calculate the amount of work which can be obtained from a *head* of water in driving water-wheels, etc., remembering, however, that there is always a *loss* (as it is usually called) due to friction, etc., in the machinery. That there is a loss in useful power is true, but we shall find presently that in energy there is none, as indeed our general result has already shown. *Where* the apparently lost energy goes is another question. Another good example of potential energy is that of the weights in an ordinary clock. It is the gradual conversion of potential into kinetic energy in the driving weight which maintains the motion of the clock, in spite of friction, resistance of the air, etc.; and we have in the kinetic energy of sound (which depends on vibrations in the air) a considerable portion of the expended potential energy of the striking weight. A coiled watch-spring, a drawn bow, the charged receiver of an air-gun, are good examples of stores of potential energy which can be directly used for mechanical purposes. The chemical arrangement of the different components of gunpowder or gun-cotton is such as corresponds to enormous potential energy, which a single spark converts into the equivalent active amount. But here *heat* has a considerable share in the effects produced; it may then be as well, before proceeding farther, to consider how we can take account of it and other (so-called) physical forces as forms of energy.

The physical forces that require to be carefully noticed in this work may be thus classified: 1. Gravitation; 2. Molecular Forces, including Cohesion, Capillarity, Elasticity, and Chemical Affinity; 3. Heat and Light; 4. Electricity, including Magnetism. Of these, classes 1 and 2, and some forms of class 3, are more immediately connected with *matter* than the others—that is to say, that the remainder almost necessitate the hypothesis of the existence of some medium unlike ordinary matter, or, in popular language, an *imponderable*. The almost universal opinion of physicists, however, seems to be that even the former must be accounted for in some such way. Of what that medium might consist we cannot, of course, hazard even a conjecture; but if it be composed of separate atoms—i.e., not continuous—it is evident that a second medium will be required to help the particles of the first to act on each other (for without this the first medium would be merely obstructive), and so on. This must stop somewhere; why not, then, at the first? But in the present state of our understanding of mechanics a continuous medium is barely conceivable, and its motions, etc., present considerable difficulties to even plausible mathematical treatment. If we take the view opposed to Newton's, as Mosotti and others have done (their ideas are considered farther on), we can, in a very artificial manner, however, account for gravitation and molecular action; but, as before said, the foundations of this attempt at explanation are hardly tenable. Just as sound depends on the elasticity of the air and vibrations thereby maintained and propagated, light and radiant heat, which are certainly identical, most probably consist in the vibrations of some very elastic fluid. This has been provisionally named ether. If it be continuous, it may help us to account for the first two categories of force also, as we have already seen; if not so, as is more likely, fresh difficulties arise. Light and heat, however, undoubtedly depend on motion, and correspond, therefore, to so much of vis-viva or actual energy. Even heat in a liquid or solid body must correspond to some vis-viva in the material particles, since a hot body can give out both light and heat, and a body may be heated by luminous or calorific rays which are vibratory, as we have seen. Class 4 contains perhaps the most puzzling of all these forces. That there is something in common in all the forms of electricity, and that magnetism is nearly related to them, is certain; it is probable, also, that frictional electricity, when statical, consists in something analogous to a coiled spring, or is one form of potential energy—the others being forms of kinetic energy. Some have supposed magnetism to be also a form of potential energy, but Ampère's discoveries have materially lessened the probability of the truth of this hypothesis. We shall consider this again.

These forces can be transformed one into another. Take the potential energy of gravitation to commence with. We can employ it to drive a water-wheel. This turns a shaft, to which, if a tight brake be applied, heat will be produced by friction, and light also, if a rough wheel on the shaft be made to rotate against a piece of flint or pyrites; or electricity may be produced by employing the moving power to turn an ordinary electrical machine, or a magneto-electric one; and from the electricity so produced electrical charges and currents may be derived; from them heat and light again. Or the currents may be employed to magnetize a needle or a piece of soft iron, or to produce chemical decomposition. Again, heat may be employed by means of a steam-engine as a substitute for the water-power or potential energy of gravitation, and the above effects be produced. It may also be employed in raising weights, and therefore in producing the potential energy in question; or it may be employed to produce thermo-electric currents, and thence all the ordinary effects of electricity, including the motion of a magnetic needle. Light may be employed to produce chemical combination or decomposition, as we see in photography; it may also by the same means be made to produce electric currents, and consequent *motion* of a needle. It is not yet proved that light can produce magnetism *directly*, though there can be little doubt that, if properly applied, it is capable of doing so. Chemical action in a voltaic battery can be made to produce motion, heat, light, electricity, electrical charges and magnetism, and to overcome other chemical affinity. Capillary action has been employed to produce electricity and mechanical effects, etc., but we need not go through the whole category. In these experimental results, then, consist what is called the correlation of the physical forces—i.e., the transmutability of one of the latter into another or others. The idea is old, but the proofs of its truth have only become numerous within the last half-century. Grove has published an excellent treatise with the above title; to this we refer the curious reader for further detail on this interesting subject.

A far more important principle, being, in fact, the *precise* statement of the preceding—which is somewhat vague—is that of the conservation of energy. It is simply the extension (to all physics) of the principle which we have given in full, and proved in a particular case, at the beginning of this article—i.e., that the sum of the potential and kinetic energies of any set of moving bodies cannot be altered by their mutual action. Let us now suppose heat, light, etc., to consist in the energy of vibratory movements of particles, and in their relative states of distortion, etc., and make the supposition that these particles act on each other—no matter by what means—in the line joining each two, and with forces which depend on their distance, and we have at once the theorem that the sum of the potential and kinetic energies is a quantity unalterable in any system, save by external influences. Hence, when mechanical power is said to be lost, as it is by the unavoidable friction in machinery, etc., it is really only changed to a new form of energy—in general, heat. Thus, when a savage lights his fire, he expends animal energy in rubbing two pieces of dry wood together. If these pieces of wood were not in contact, no force would be required to move them past each other—more and more is required as they are more strongly pressed together. The equivalent of the energy so expended is found in the heat produced. Davy showed that two pieces of ice might be melted by rubbing them together. A skillful smith can heat a mass of iron to redness by mere hammering. Here the energy actually employed is partly given out in the shape of heat, and partly stored up in the iron as potential energy due to the compression of the mass, or the forcible approximation of its particles. Amongst the earliest, and certainly the *best* experiments on this subject, are those of Joule. He determined the relation between the units of heat and potential energy of gravitation by various methods, which gave very nearly coincident results. One of these we may mention. A paddle-wheel is so fixed as to revolve in a closed vessel full of water. The wheel is driven by the descent of a known weight through a measured space, and precautions are taken against losses of energy of all kinds. The water agitated by the paddle-wheel comes soon to rest, as we know; but this is due to friction between its particles; and the final result is the heating of the water The quantity of water, and also the number of degrees by which its temperature is raised, being measured, a simple proportion enables us to find how many foot-pounds of mechanical energy correspond to the raising by one degree the temperature of a pound of water. The result is that the heating a pound of water one degree Fahrenheit is effected by 772 foot-pounds—and this number is called Joule's equivalent. In other words, if a pound of water fall to the ground through 772 feet, and be then suddenly arrested, its temperature will be raised one degree; and, conversely, the heat that would raise the temperature of a pound of water one degree would, if applied by a steam-engine or otherwise, raise 772 pounds one foot high. Now we know the amount of heat which is produced by the burning (in air) of any material whose composition is known. It follows, then, that from the mere quantity and composition of a substance we can tell the amount of mechanical work due to its combustion; that is, supposing it all to be effective.

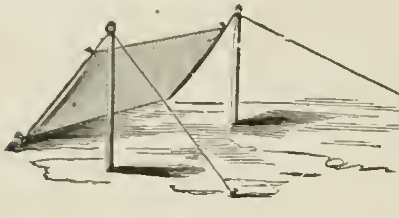
An immediate consequence of the truth of the conservation of energy is the impossibility of what is usually understood by the perpetual motion; for it is to be carefully remembered that perpetual motion, in the literal sense of the words, is not only possible, but very general. If there were no such thing as friction, or if we had a perfectly smooth body, in the form of a teetotum, for example, it would spin forever in vacuo with undiminished speed. The earth in its axial rotation affords a good example. Were it a perfect sphere, and of uniform material, the other masses of the system could produce no effect whatever on its rotation, and the latter would remain forever unchanged. And even, as we have already seen, when one form of kinetic energy, as electricity, or ordinary vis-viva, is lost, we find it reappearing in other forms of kinetic energy, such as heat and light. But this is not the technical acceptation of the term, the perpetual motion; it is popularly understood to mean a source of motion which will not only preserve its own vis-viva unchanged, but also *do work*. This is, of course, incompatible with the conservation of energy, for wherever work is done, equivalent energy in some form or other is consumed. The ordinary attempts to obtain "the perpetual motion" which are still being made in thousands by visionaries are simply absurd, based as they are for the most part on ignorant applications of mechanics. There is absolute impossibility here; and a "perpetual motionist" of the common herd is far more infatuated than a "squarer of the circle;" for the latter's problem *may* be solved, although certainly not by the means usually employed, or in the form usually sought for. There are, in mechanics, several other quantities which retain a fixed value under certain circumstances. We may briefly consider a few of them.

Conservation of Areas.—We have seen in the article CENTRAL FORCES that if a particle move about a center of force, its motion is confined to a plane, and its radius vector traces out equal areas in equal times. Similar theorems hold in any system of particles acted on only by their mutual attractions. If in such a system we suppose the positions of the respective particles to be continually projected (orthogonally) on *any* fixed plane, and radii vectores to be drawn from *any* point in that plane to the projections—*the sum of the areas swept out by all those radii vectores will be equal in equal times.* Also, this being true of all planes, there is one for which this sum is a maximum, and *this plane is fixed in space.* It is thence called the invariable plane of the system. Similar propositions hold for a system of bodies each of finite size, their several axial rotations being taken into account; hence what is called the invariable plane of the solar system.

Conservation of Momentum.—When two masses attract or impinge, the forces they exert on each other are evidently equal and opposite. Now, the measure of a force is the momentum it produces; hence equal and opposite momenta, in addition to their original quantities, will be communicated to the masses, and therefore the sum of the momenta of the two, resolved in any direction, will be unaltered; hence *the sum of the momenta of any number of bodies will be unaltered by mutual actions either of the nature of attraction or impact.*

Conservation of the Motion of the Center of Gravity.—Again, in such a system, the momentum of the whole collected at its center of inertia, resolved in any assigned direction, is the sum of the momenta of the separate bodies in that direction; hence *the center of inertia of a system subject to none but the mutual actions of its components either remains at rest or moves uniformly in a straight line.* See *Center of Gravity, Central Forces, Couples, Energy, Falling Bodies, Gravity, Mechanical Powers, Motion, Parallelogram of Forces, Velocity, Virtual Velocities*, and *Work*.

FORCED MARCHES.—Whether forced marches are offensive or defensive, the important considerations are to travel rapidly without encumbrance and to have at hand all things necessary for the comfort and safety of the command. The matter of proper equipment for the forced march is frequently a difficult one, when the element time is an uncertain factor, and the character of the country to be traveled over is unknown. Assuming that, in case of necessity, the country will afford the necessary supplies, the question of most proper equipment may be easily disposed of in particular cases. Whether the troops are mounted or not, the equipment should be selected so as to avoid all strains and unequal pressures; and, with a constant view to comfort and convenience, the useful points should be most numerous and the weight *in toto* a minimum. Of course, the time will never come when regular troops will scout or campaign without tents; but there is no doubt as to the bivouac, a temporary makeshift, being far preferable to tenting in a dangerous or rugged mountainous country. Bivouacking is not only healthier, in consequence of the soldier inhaling purer air, but he is enabled to better see and hear, and does not indicate to sneaking hostiles the exact spot where he is lying and enable them to move accordingly. A mound of sand or earth, covered by a cloth or blanket, will make an excellent pillow; whilst a blanket judiciously pitched over a little turned-up earth or an accumulation of twigs, leaves, or grass, serving as a comfortable bed, will afford a shelter surprisingly complete so far as protection from cold winds or drifting rains is concerned. This plan of flying camps could be very advantageously carried out by transporting extra *combination-blankets*, so made as to admit of being worn as aprons when moving through wet bushes or during rainy weather, and to be packed, when not in use, singly or in great numbers (as horse-blankets) upon any loose stock that may accompany the command. The blankets will prove invaluable for many purposes after the march is completed, even if it is not desirable to adjust them as shelters. The Indians of the Northwest, when traveling rapidly, invariably



transport extra blankets on the led-horses, and make such uses of them as the nature of the weather necessitates. When not engaged in forced marches, and when not compelled to leave the means of transportation, the men should bear only their rifles, ammunition, intrenching-tools, and at times canteens. The haversack and contents are useless and burdensome. It is not needed during an ordinary march, and is certainly in the way about the time of an engagement. A few pieces of hard bread placed in the hip-pocket of the soldier do not incommode him and are always attainable, whereas the haversack is often lost, and oftener abandoned before the soldier has had an opportunity to attend to his hunger. See *Farrow Combination-tent* and *Route-marches.*

FORCES.—An army of all branches—artillery, cavalry, and infantry. The word is sometimes used in the singular number, but with the same signification. The *effective forces* comprise all the efficient parts of an army that may be brought into action, with their necessary appendages, such as Hospital Staff, Wagon-train, etc. The Navy of a country must be looked upon as part of the effective force of the country, to which is added the Marines.

FORCING.—As applied to a projectile, forcing is the operation by which it is made to take hold of the grooves of a rifled barrel and follow them in its passage through the bore. It may be accomplished in various ways, most of which depend upon the soft and yielding nature of lead, the material of which small arm projectiles are made, viz.: 1. By the action of the ramrod. 2. By the action of the powder. 3. By the action of ramrod and powder combined. 4. By the form of the bore or projectile, as in breech-loading arms, etc.

When rifles were first made, forcing was effected by making the projectile a little larger than the bore, and driving it down with a mallet applied to the point of the ramrod; although this caused the lead to fill the grooves completely, converting the projectile into a screw, whereof the barrel was the nut; the operation was slow and laborious, and the accuracy of the projectile was impaired by the consequent disfiguration. The form of the grooves then used is shown in Fig. 1. They were liable to be injured by the ramrod, and were difficult to clean.

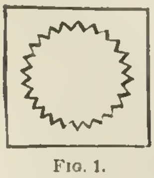


Fig. 1.

The foregoing plan was improved by making a projectile a little smaller than the bore, and wrapping it with a patch of cloth, greased, to diminish friction in loading. The thickness of the cloth was greater than the windage; this caused the patch to press upon the projectile with so much force as to compel it to follow the winding of the grooves without materially altering its shape. The patch is still used in sporting-rifles, and gives excellent results; but the loading is too slow and difficult for a military arm.

M. Delvigne, an officer of the French infantry, appears to have been the first person who overcame the difficulty of loading rifles, thereby removing the principal obstacle to their introduction into the military service. The plan proposed by him, in 1827, was to make the projectile small enough to enter the bore easily, and to attach it to a *sabot*, or block of wood (*a*) (as shown in Fig. 2), which, when in position, rested

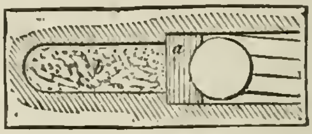

Fig. 2.

upon the shoulders of a cylindrical chamber (*b*) formed at the bottom of the bore to contain the powder. In this position the projectile was struck two or three times with the ramrod, which expanded the lead into the grooves of the barrel. To the bottom of the sabot was attached a piece of greased serge, which served to soften the residuum of the powder and facilitate the loading. By this plan the accuracy of the round projectile was increased, but its range was diminished.

In 1742 Robins pointed out the superiority of the oval or elongated form of projectile, and since this many attempts have been made to employ it in rifled arms, especially in this country; but it remained for M. Delvigne, followed by MM. Thouvenin and Minié, of the French service, to apply it successfully to the military service. The form of projectile proposed by these officers was composed of a cylinder and conoid. The cylinder served as the base of the projectile, and gave it stability in the bore of the piece; the conoidal surface, which formed the point, was well adapted to diminish the effect of the air, by increasing the penetrating power of the projectile. A single groove was formed around the cylinder, to contain a greased woolen thread, in place of the woolen patch of Delvigne. It was shown by the trials which followed that the presence of this groove improved the accuracy of the projectile—a fact which gave a new turn to the investigations, and led to the adoption of two additional grooves. The theory advanced in explanation of the action of these grooves was, that they oppose a resistance to the air which, acting on the rear portion of the projectile, tends to keep the point foremost in flight, thereby rendering the resistance of the air uniform, and at the same time a minimum. The correctness of this theory may be well questioned;

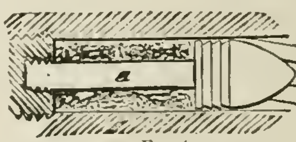

Fig. 3.

but that the grooves exert a beneficial effect, by diminishing adhesion to the surface of the bore, and by facilitating expansion, can scarcely admit of a doubt.

Colonel Thouvenin proposed to replace the chamber of Delvigne by a spindle of iron, screwed into the center of the breech-screw (see *a*, Fig. 3). This was found to be an excellent point of support for the base of the elongated bullet when forced by the blows of the ramrod. The expansion of the lead into the grooves secured the bullet in place, and protected the powder from moisture. Considerable difficulty, however, was experienced in cleaning the space around the spindle; and, like all plans of forcing by the ramrod, it is subject to variation, arising from the particular care and strength exercised by the soldier.

The method of forcing by form of projectile is illustrated in the Whitworth rifle. The form of the bore, as in the cannon, is a twisted hexagonal prism, making a complete turn in 20 inches. The projectile is made nearly of the exact form and size of the bore, and is about three diameters in length. To prevent disfiguration and stripping, which are very liable to occur in bullets of this length, fired with high velocities, the lead is hardened by alloying it with tin and manganese; and to obviate fouling a greased wad is placed between the powder and bullet. As might be expected from the length of the bullet, the amount of twist, and the extreme accuracy with which the bullet fits the bore, the results obtained with this arm are much superior to those obtained with service-arms.

It appears that the first attempt to force a projectile by the action of the powder was made by Mr. Greener, an English gunsmith, in 1836. The plan which he tried consisted in forming a cavity at the base of an oblong bullet, and partially inserting in it a conical pewter wedge, which was driven in by the force of the powder in such manner as to expand the outer part of the bullet into the grooves of the barrel. Some years after this Colonel Minié produced a projectile constructed on the same principle, but, instead of a solid wedge, he used a cup of sheet-iron, which was inserted into a conical cavity (as seen in Fig. 4), at the base of the bullet. The point of the ball was cut off to prevent disfiguration by the flat head of the ramrod. This projectile, when fired from a rifle of service-caliber, generally possessed great range and accuracy; but it had certain defects which prevented it from being extensively used in the military service, viz.: it was compound in its structure; the cup was sometimes forced in obliquely, producing unequal expansion; and, from the large size of the cavity, the top was occasionally blown off, leaving the cylindrical portion adhering to the sides of the bore.

Fig. 4.

Not long after the introduction of the Minié bullet it was discovered that, by giving a suitable size and shape to the cavity, the wedge could be dispensed with. The projectile thus obtained was simple in its structure, and gave better and more reliable results than the one from which it was derived. The particular form and mode of expanding bullets varies in most military services; in general terms, however, all modern small-arm projectiles are *cylindro-conoidal* in shape, and a majority of them are forced by the action of the powder. The effect of the powder may be direct, as in the case where it acts in the cavity of a bullet; or it may be indirect, as when it compresses the bullet lengthwise, or, as it is technically termed, "upsets" it. See *Small-arm Projectiles.*

FORD.—When a river or rivulet is crossed without the aid of either a bridge or ferry, it is said to be forded, and an established place for this crossing is called a ford. Thus we have Oxford, Stratford, Deptford, Hungerford, etc., towns built around ancient fords. To the military engineer and the traveler in wild countries the selection of the safest place for fording a river is a matter of some practical importance. In the first place, the *widest* part of the river should be chosen, as, wherever a certain quantity of water is flowing, the wider its bed—the rapidity of the flow being the same—the shallower it must be. At the bend of a river the line of shallow water does not run straight across, but extends from a promontory on one side to the nearest promontory on the other. The stream usually runs deep along hollow curves, and beneath steep perpendicular and overhanging banks, whilst it is always shoal in front of promontories, unless the promontory is formed by a jutting rock. For safe fording on foot the depth of water should not exceed 3 feet; on horseback, 4 feet; or a foot less for each if the current be very strong. The bottom of a ford should be firm and even; weeds, blocks of stone, etc., are serious obstacles, especially for cattle. When a caravan, a number of troops or of cattle, have to cross, a sandy bottom is very bad, for the sand is stirred up and carried away by the stream, and renders the ford impracticable for the hindmost. For a small party hard sand or gravel is the safest bottom. The inhabitants of a district generally know the safest fords, and their experience affords a better guide than the best rules that can be given. Fords are continually varying, either from the swelling of the river or the shifting of its bed or banks, and therefore it does not follow that the place set down by one traveler as a safe ford will continue so for the next that succeeds him.

The best ford seldom leads directly across a stream, but must be selected at a point where the width of the stream is greater than usual, with the point of egress some distance down stream, in order that those crossing may secure the advantage of the current. In certain cases, however, owing to the formation of the river-banks, it is necessary to ford obliquely up the stream. This is always attended with much labor and difficulty, and frequently in the struggle with the current the footings of men and animals are lost. In such cases it will accomplish much if mounted men are placed at suitable points, to urge forward with whips any animals that do not work properly. To insure reaching the proper point of egress, some of the animals will need frequent assistance by means of attached lariat-ropes. When the river is deep and rapid, in consequence of the body's buoyancy diminishing its power to resist the action of the current, it might be well to place a heavy rock in the arms before entering the ford. When the different arms cross a ford separately, the infantry should precede the cavalry and artillery; otherwise they would destroy the bottom and render the crossing for the infantry difficult or impossible. While fording, it is important to direct the eyes to some fixed point upon the shore and not look at the water, and particularly when the water-course is broad or the current rapid. See *Bridges.*

FORE CARRIAGE.—That portion of a wagon consisting of the frame (formed by the sweep-bar, the splinter-bar, and futchells), the axletree together with its connections, and the front wheels.

FOREIGN ARMIES.—Looking at the armies of Europe from every point of view, their strength, the rapidity with which they can be mobilized, and the means of feeding them, they may be classed as follows:

First class...	1. Germany.
	2. France.
	3. Russia.
	4. Austria.
Second class.	5. Italy.
	6. England.
Third class..	7. Belgium.
	8. Turkey.
Fourth class.	9. Sweden and Norway.
	10. Holland.
	11. Denmark.
	12. Spain.
	13. Portugal.
	14. Switzerland.
	15. Greece.

The four armies of the first class can place together in the field, in round numbers, a combatant force of 3,400,000 men and 8652 guns, whilst they can count twice that number of men on paper. The expense of these armies exceeds £67,000,000 per annum. Russia, Turkey, and Austria keep their troops at least cost, viz., from £25 to £29 a year per man; the maintenance of the British soldier is by far the dearest, as it amounts to close upon £100 per annum. In Germany the cost is £38 11*s.* per man. Of the above-named fifteen States of Europe, seven have introduced the compulsory service as the means of raising their armies—Germany, Russia, Austria, France, Italy, Denmark, and Switzerland. Seven are recruited by conscription, or conscription and enlistment, viz., Spain, Turkey, Sweden and Norway, Holland, Belgium, Portugal, and Greece. The British army alone is solely dependent on voluntary enlistment. In the following armies the age for joining the Colors is 20, viz., Austria, France, Russia, Spain, and Switzerland; 21 in Germany and Sweden; 19 in Belgium; 18 in Italy; and 22 in Denmark and Norway. In England men enlist between 18 and 25. The term of service in Austria, Germany, Italy, and Greece is 12 years; in Russia, 15; in France and Turkey, 20; in England, 12; in Denmark, 16; and in Switzerland, 10. The direct term of army service—that is to say, the term the recruit or the conscript has to remain in the active army before entering the Reserve (exceptions omitted)—is, in Austria, Denmark, France, Germany, and Italy, 3 years; in England, 6; in Sweden and Norway, 5; in Turkey and Russia, 4. The training of a recruit lasts in Austria 8 weeks; Germany and Italy require but 6; Russia deems 26 requisite; France finds 13 sufficient; England, 16; whereas Turkey considers 12 weeks necessary for the drill-education of her soldier. The active army in Austria is composed of the Line, Reserve, and eventually of the *Landwehr*, together with the Substitute Reserve. In Germany the active army is composed of the same parts. Russia forms hers of the Line, Reserve, and Militia, who have served but 4 years in that branch of the army. France has her Active Army and her Reserve, followed by the Territorial Army and the Reserve of the Territorial. As in the case of Russia, her Reserves as well as her Territorial Armies are but on paper, as sufficient time has not elapsed for the new system to mature. Italy has the Line and the *Mobile Milizia*. In Turkey the active army is followed by three reserves, the *Idatyal*, the *Rédif*, and the *Ilyade*, the latter being a kind of *Landsturm*. In the six principal armies of Europe the proportion of guns and cavalry on active service to the strength of infantry is as follows:

Austria has....	103 cavalry	and 4 guns		per 1000 men.
France	119 "	" 3 "		
Germany	117 "	" 3 "		
Russia (Europe).	178 "	" 4 "		
" (Asia) ..	910 "	" 3 "		
England.......	133 "	" 4 "		
Italy	57 "	" 3 "		

The Austrian infantry is armed with the Werndl rifle, the Bavarian with the Werder, and the remainder of the German infantry with the Mauser rifle. France is gradually providing her troops of the line with the modified Chassepot called the Gras rifle, from the name of the officer who has improved this weapon. Denmark, Norway and Sweden use the Remington rifle. Italy and Switzerland have adopted the Vetterli rifle, Russia the Berdan, and Spain the Remington. Belgium has found the Albini-Braende rifle superior to all, and England and Turkey the Martini-Henry. The American troops are armed with the Springfield rifle. Before closing this article on the small-arms of the several foreign armies, a statement of the guns used by the four largest Continental powers may be considered interesting. The field-batteries of the German army are armed with the 8.8-centimeter B.L.R. gun, firing a shrapnel of 17 lbs. weight; the horse-artillery with the 7.85-centimeter B.L.R. gun, firing a shrapnel weighing 12.2 lbs. These guns are made of cast-steel, with polygrooved rifling and wedge-break action. For siege purposes the Germans use the 12-centimeter (4.68-inch) bronze gun, firing a 29-lb. shell, and steel and bronze guns of 15-centimeter (6.85-inch) caliber, firing a 54-lb. shell. A 21-centimeter shell gun is soon to be added to this arm. The field-artillery of Austria is composed of 8-pdr. and 4-pdr. bronze rifled guns, having calibers of 3.9 inches and 3 inches, firing 14-lb. and 8-lb. shell respectively. Steel B.L.R. guns of the Prussian type are, however, being gradually introduced. The mountain-batteries are armed with 3-pdr. rifled bronze guns; and for siege and garrison purposes the guns in use are B.L.R. 15- and 21-centimeters and 8-inch bronze guns. The Russian field-artillery is now armed with both cast-steel and bronze B.L.R. guns, 4-pdrs. and 9-pdrs. of 3.3-inch and 4-inch calibers, firing 12-lb. and 24-lb. shell respectively. For siege and garrison artillery they use 12-pdr. and 24-pdr. guns, throwing 30-lb. and 63-lb. shells, and 8-inch bronze and steel guns. The mountain-gun is a 3-pdr. bronze rifled gun, and fires a 9-lb. projectile. The field-guns of France are the 14-pdr. steel and 10-pdr. bronze B.L.R., the former the production of Colonel Reffye, the latter made by Major Pothier, and a steel 7-pdr. B.L.R. gun of a new pattern.

FOREIGN AUXILIARIES.—In the early periods of English history, the Foreign Auxiliaries were by no means uncommon. Harold had a body of Danes in his army when he defeated the Norwegian King, and to their refusal to march against the kindred Normans he owed not the least among the complications which ultimately overwhelmed him. Passing to modern times, William III. had for some time a body of Dutch troops in his pay as King of England; throughout the eighteenth century, Hessian and Hanoverian regiments were constantly in the pay of the English Government for temporary purposes. Hessians fought for the English in the first American war; and the Landgrave of Hesse, who sold his troops at so much a head, received upwards of half a million for soldiers lost in the campaign. During the Irish Rebellion, again, in 1798, many Hessian troops were employed.

On the outbreak of the Continental War in 1793, it was determined to recruit the British army by the addition of a large body of foreigners; and accordingly, in 1794, an Act was passed for the embodiment of the "King's German Legion," consisting of 15,000 men. These troops, who were increased in the course of the war to at least double that number, distinguished themselves in various engagements, and formed some of the regiments on which the Generals could best rely. Corps of French *Emigrés*, as the York Rangers and others, were also organized. The whole of the Foreign Legions were disbanded in 1815, the officers being placed on half-pay.

During the Russian War, in 1854, the British Government again had recourse to the enlistment of foreigners; special provision being made, in the Act authorizing their employment, that the arms of the Legionaries were in no case to be used against British subjects, in the event of internal discord. The numbers to be raised were 10,000 Germans, 5000 Swiss, and 5000 Italians; the pay to be the same as to British troops, but temporary service to convey no claim to half-pay. About half the number of men were enrolled, and were said to have reached great efficiency, when the stoppage of hostilities arrested their progress, and caused them to be disbanded at a great cost for gratuities, etc.

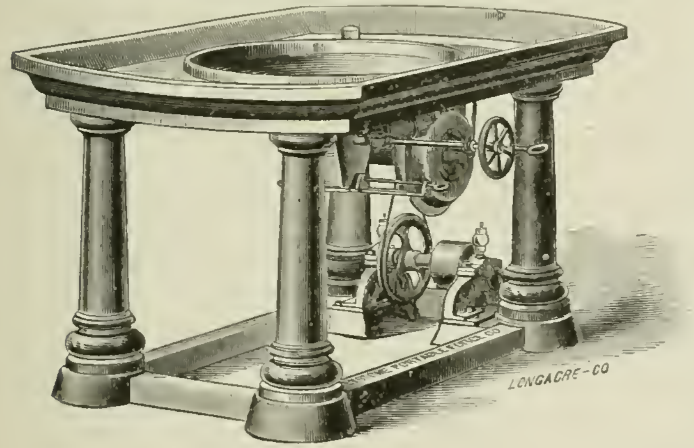
The Swiss Auxiliaries used to form a regular contingent in many of the armies of Europe, especially of France and of Italy. Over 1,000,000 served in France from the time of Louis XI. to that of Louis XIV. (1465–1715). See *Gardes Suisses*. Usually the Swiss served only on condition of being commanded by their own officers, and occasionally these officers obtained distinction and fame. But the privates returned home poor and often demoralized; and the Cantons which supplied most mercenaries suffered severely by their absence. After the French Revolution, the Cantons ceased publicly to hire out their subjects; and after 1830 most of the Cantons forbade foreign enlistment. In 1859 the Confederacy passed a severe law against recruitment for service abroad. There is still, however, a large contingent of Swiss as mercenaries in the Dutch East Indian Colonies. The Papal Swiss troops have shrunk to a body-guard of about 100 men.

FOREIGN-ENLISTMENT ACT.—In the law of England there was a statutory prohibition of enlistment in the service of a Foreign Prince. It provides that if any British subject shall agree to enter the service of any Foreign State, either as a soldier or a sailor, without the license of her Majesty, or an Order in Council or Royal Proclamation, or if any person within the British Dominions induces any other person to enlist in the service of a Foreign State, such a person shall be guilty of a misdemeanor. The Officers of the Customs, on information on oath, may detain any vessel having persons on board destined for unlicensed Foreign Service. Masters of vessels, knowingly having such persons on board, are punishable by fine or imprisonment, or both. Persons building any vessel for Foreign Service, without license, are guilty of a high misdemeanor, and the ship and stores are forfeited. Even to assist a Foreign State with warlike stores, without license, is a misdemeanor punishable with fine and imprisonment. These penalties are irrespective of any consequences that may follow to the individual for having committed any breach of international law.

FORELAND.—In fortification, the piece of ground between the wall of a place and the moat.

FORE-SIGHT.—1. A sight *forward* at the leveling-staff or through the sights of the circumferentor. 2. The muzzle-sight of a gun. See *Front Sight*.

FORGE.—The process of hammering red-hot iron or steel into any required shape is called forging, and the workshop in which the operation is performed, a forge. The principal tools of the common smith's forge are the forge-fire or hearth, with its bellows, the anvil, and the various hammers, swages, etc. For large work, an air-furnace, blown by steam-bellows, supplies the place of the simple hearth of the blacksmith, powerful cranes swing the work to its place on the anvil, and a steam-hammer strikes the blows that squeeze the red-hot mass into shape. Besides these, there are portable forges of various sizes and forms, used for military and other purposes. They usually consist of an iron frame, to which a bellows, worked by the foot, is attached; and above the bellows is an iron tray, with a hearth, etc., upon which the fire is made; and the anvil is either attached to this frame or has a separate stand.



Power-forge.

For the largest work to which hand-hammers are still applied, two gangs of from six to twelve hammermen are employed; they swing the large hammers with such wonderful precision and regularity that the instant one hammer is withdrawn another falls upon the same place. A foreman, with a wand, directs the hammering. The two gangs relieve each other alternately, on account of the great severity of the labor. Shovels, spades, mattocks, and many other tools and implements, are partly forged under the tilt-hammer.

The drawing shows a power-forge weighing 500 pounds, with a fire-pan 36×54 inches. It is well adapted for armory work, excelling in the arrangement of the gearing, strength of blast, and general working capacity. It is furnished with the Keystone fan-blower and revolving tuyere. This forge is well arranged for rapid work, and in all processes of forging it is of primary importance to obtain the greatest possible rapidity in the succession of the blows. There is a double reason for this: first, and simply, that the work is cooling, and the more slowly it is forged the more frequently it must be reheated; and secondly, that percussion generates actual heat, and when the blows are sufficiently heavy and rapid, the temperature of the work may be fully maintained out of the fire for some considerable length of time. The hammer used for tilting steel not only maintains the heat of the bar, but it raises it from a dull to a bright red heat. See *Cavalry Forge*.

FORGE-WAGON.—A wagon consisting of the body of an ammunition-wagon, carrying a movable frame for the bellows, hearth, anvil, etc., and the limber in which the necessary tools are conveyed.

FORLORN HOPE.—The body of men selected to attempt a breach or to lead in scaling the wall of a fortress. The name (which in the French, *enfants perdus*, is even more expressive) is given on account of the extreme danger to which the leaders of a storming-party are necessarily exposed. As, however, the honor of success is proportionate to the peril of the undertaking, there is ordinarily no lack of volunteers for this arduous service. The forlorn hope is called by the Germans *Die verlornen Posten*.

FORM.—In a general acceptation of the term, to assume or produce any shape or figure, extent or depth of line or column, by means of prescribed rules in military movements or dispositions. To *form on* is to advance forward, so as to connect with any given object of formation, and to lengthen the line.

FORMATION.—A term applied to that particular arrangement of the troops composing any unit when this latter is waiting for battle or is prepared to execute a movement. That portion of the formation upon the side towards the enemy is known as the *front;* the side opposite to the front is designated the *rear;* the lateral extremities are known as *flanks*. Any row of soldiers placed parallel to the front is known as a *file;* the number of ranks measures the depth of the formation.

FORMERS.—Round pieces of wood that are fitted to the diameter of the bore of a gun, round which the cartridge-paper, parchment, lead, or cotton is rolled before it is served. *Cartridge formers* are wooden shapes for cutting out the form and size of cannon cartridge-bags; their size and shape depend on the nature of the cartridge to be made. *Port-fire-formers* are used for making port-fire cases. They are made of wood, of a diameter slightly larger than the port-fire setting-drift. *Signal-rocket-formers* are used for forming the cases of signal-rockets. They have a movable piece from two to three diameters in length, which is termed the nipple, the smaller end of which fits into a hole made in the *former*, and when slightly drawn out keeps the neck of the case open while the choke is being formed and secured. *Wad-formers* are flat circular pieces of wood, hollowed out and grooved. They are employed for making up grummet-wads for guns.

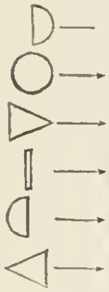
FORM OF PROJECTILE.—When a body moves through the air the gaseous particles in front are crowded upon each other until they meet with a certain resistance, after which they move off laterally, and finally pass around and arrange themselves in rear of the moving body. It is evident that the difference of the densities, or pressures, front and rear, depends on the velocity with which the displaced particles rearrange themselves after displacement; and this in turn depends on the shape and extent of the surfaces of the moving body. The best form for a projectile can only be determined by experiment, as theory and experiment do not agree in their results. According to theory, if a plane of given area be moved through the air, it meets with a resistance which is proportional to the square of the sine of the angle which its direction makes with that of motion.

The experiments of Hutton with low velocities show that this is only true in cases of 0° and 90°; that from 90° up to 50° or 60° the resistance is nearly proportional to the sine; beyond this it decreases a little more rapidly than the sine, but not so rapidly as the square of the sine:

For an angle of 22° it is only ½ }
14° " " " ⅓ }
9¼° " " " ¼ } the resistance proportional to the sine.
4° " " " ⅕ }
2° " " " ⅙ }

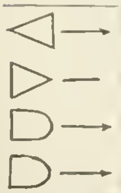
The following are the results of the experiments made by Hutton and Borda on the resistances experienced by different forms of solids moving through the air with velocities varying from 3 to 25 feet per second:

HUTTON'S EXPERIMENTS. VELOCITY, 10 FEET.



Kind of surface.	Experimental resistance.	Theoretical resistance.
No. 1, Hemisphere (convex surface in front)	119	144
No. 2, Sphere	124	144
No. 3, Cone, elements inclined to the axis 25° 42′	126	53
No. 4, Disk	285	288
No. 5, Hemisphere (plane surface in front)	288	288
No. 6, Cone (base in front)	291	288

BORDA.



Kind of surface.	Experimental resistance.	Theoretical resistance.
No. 1, Prism, with triangular base	100	100
No. 2, " "	52	25
No. 3, " semi-ellipse	43	50
No. 4, " ogee	39	41

The foregoing experiments show: 1st. That the results of theory do not agree with those of practice. 2d. That rounded and pointed solids suffer less resistance from the air than those which present flat surfaces of the same transverse area; but at the same time the sharpest points do not always meet with the least resistance. 3d. That where the front surfaces were the same the resistance was least with those in which the posterior surfaces were the flattest. 4th. That the ogeeval form, or the form of the present rifle-musket bullet, experiences less resistance than any of the others tried.

These experiments, as before remarked, were made with low velocities compared to those which ordinarily actuate projectiles, and the conclusions which have been drawn from them may not be strictly applicable in practice. Now that oblong projectiles are used in all kinds of fire-arms, it is important to determine that form which will be least affected by the resistance of the air. See *Projectiles*.

FORT.—A term technically applied to an inclosed work of the higher class of field-fortifications; but the word is often used in military works much more loosely. Detached works, depending *solely on their own strength*, belong to the class of works termed forts, and should have a revetted scarp and counterscarp of sufficient height to present great difficulties to an open assault, and have their ditches flanked either from the parapet of the work itself, or by caponieres, or by counterscarp-galleries. Their principal use is to occupy ground like commanding heights, which, although not within good sweep of the fire of the main work, is still within range of the heaviest calibers of the assailant, and which if occupied by him would prove a source of serious annoyance to the work. These detached works are also sometimes called *independent defensible works*, or simply independent works. In British North America the term *fort* is applied to a trading-post in the wilderness with reference to its indispensable defenses, however slight, against the surrounding barbarism. It has thus been often employed to designate merely a palisaded log-hut, the central oasis of civilization in a desert even larger, it may be, than Scotland. See *Advanced-works* and *Fortification*.

FORT ADJUTANT.—An officer holding an appointment in a fortress—where the garrison is often composed of drafts from different Corps—analogous to that of Adjutant in a Regiment. He is responsible to the Commandant for the internal discipline, and the appropriation of the necessary duties to particular Corps. Fort Adjutants are Staff Officers, and so receive a certain allowance per day in addition to their ordinary regimental pay.

FORTALICE—FORTELACE.—A small outwork of a fortification. The military power of the State is intrusted by the Constitution of England to the Sovereign. After having been unconstitutionally claimed by the Long Parliament in the time of Charles I., it was again vindicated for the Crown. This branch of the royal prerogative extends not only to the raising of armies and the construction of fleets, but to the building of forts, fortalices, and all other places of strength. Sir Edward Coke lays it down that no subject can build a house of strength embattled without the license of the King; and it was enacted by Henry VII. that no such place of strength could be conveyed without a special grant.

FORTIFICATION.—The records of history and the vestiges of remote civilization show that the art of fortification, in some guise or another, has been in practice throughout all nations, even in the lowest stages of social progress, and that, wherever it has been cultivated, its character has been more or less influenced not only by the natural features of the country, but by the political and social conditions of its inhabitants. There are three distinct epochs; namely, ancient, that of the Middle Ages, and modern. In its earliest applications, we find men resorting to one or more simple inclosures of earthen walls; or of these surmounted by stakes placed in juxtaposition; or of stakes alone firmly planted in the ground, with a strong wattling between them; or of timber in its natural state, having its branches and the undergrowth strongly interlaced to form an impervious obstruction, with tortuous paths through it only known to the defense. A resort to such feeble means shows not only a very low state of this branch of the military art, but also of that of the attack; as defenses of this kind would present but a slight obstacle, except against an enemy whose habitual mode of warfare was as cavalry, or of one not yet conversant with the ordinary plans for scaling. This class of fortifications for the defense of entire frontiers has been mostly met with in the east of Europe, and was doubtless, at the time, found to be a sufficient protection against those nomadic tribes that for ages have

roamed over its vast plains, and who are only formidable as a mounted force. The next obvious, and, in humid countries, necessary step, was to form walls either of rough blocks of stone alone, or of these interlaced with the trunks of heavy trees. Obstructions of this kind could only be used to a limited extent, and were confined to the defenses of places forming the early centers of population. As human invention was developed, these, in their turn, were found to present no serious obstacle to an assault by escalade; giving to the assailed only the temporary advantage of a more commanding position; and they gave place to walls of dressed stone, or brick, whose height and perpendicular face alike bade defiance to individual attempts to climb them, or the combined effort of an escalade. From the tops of these inaccessible heights, sheltered in front by a parapet of stone, and, in some cases, by a covered corridor behind them, the assailed could readily keep at bay any enemy, so long as he could be attained by their missiles; but having reached the foot of the wall, he here found shelter from these, and, by procuring any cover that would protect him from objects thrown from above, could securely work at effecting a breach by mining. It was probably to remedy this defect of simple walls and towers, which at first were nothing more than square or semicircular projections built from distance to distance in the wall itself, that flanking towers were first devised, and which subsequently were not only inclosed throughout, but divided into stories, each of which was provided with loop-holes to flank the adjacent towers and the straight portions of the wall between them. Each tower could be isolated from the straight portion of the walls adjacent to it by an interruption at the top of the wall, over which a communication between the tower and wall could be established by a temporary bridge. These formidable defenses were, in their turn, found to be insufficient against the ingenuity and skill of the assailant, who, by means of covered galleries of timber, sometimes above ground and sometimes beneath, gradually won his way to the foot of the wall, where, by breaking his way through it, or by undermining and supporting it on timber props to be subsequently destroyed by fire, he removed the sole obstruction to a bodily collision with the assailed. These methods of assault were in some cases supported by means of high mounds of earth which were raised in an inclined plane towards the walls, and sometimes carried forward to them, from the top of which the assailant, by the erection of wooden towers covered with raw hides to secure them from being burnt, could command the interior, and, driving the assailed from the walls, gain a foothold on them by lowering a drawbridge from the wooden tower.

These changes in the attack led to new modifications in the defense, which consisted in surrounding the place by wide and deep ditches, of which the walls formed the scarp, the counterscarp being either of earth or revetted. This placed a formidable obstacle to the mode of attack by mining, and also to the use of earthen mounds, as these last had to be constructed across the ditch before they could gain sufficient proximity to the wall either to form a communication with its top, or to breach it by means of the battering-ram; the ditches also were filled with water whenever this obstruction could be procured, and when dry they formed a defile through which the assailed often sallied upon the assailant with success when found at a disadvantage in it. The gigantic profile often given to the fortifications of antiquity seems almost incredible, as well as their extent. In many cases a double wall of stone or brick was filled in between with earth, forming a wide rampart upon which several vehicles could go abreast. Not only was the space inclosed by some of these fortifications sufficient for the habitations, but ground enough was taken in to add considerably to the food of the inhabitants and cattle, for the long periods to which blockades were in many cases extended when all other means of reducing the place had failed. The wall built by the Romans between Carlisle and Newcastle to restrain the incursions of the Picts into the southern portions of the Island was 16 miles in extent, about 12 feet in height, and 9 feet in thickness. The extent and dimensions of this work sink almost into insignificance when compared with those of the celebrated wall of China, built to restrain the incursions of the Tartars. This structure is about 1500 English miles in length; has a height of 27 feet; its thickness at top is 14 feet. The lower portion of it is built of dressed stone, the upper of well-burned brick. It is flanked at distances of about 80 yards apart by towers in which iron cannon are found. In the great extent it embraces it necessarily crosses hills and valleys, and in many places important defiles. An examination of its parts has shown that in its plan there was an evident design to adapt it to those features of its site, as it is well thrown back to the rear of difficult passes; and at points where there is most danger to be apprehended from attempts of invasion there are several walls in succession. The mode of attack of fortified places resorted to by the ancients was reduced to settled rules, and brought to the highest state of perfection by the Greeks, about the epoch of Alexander the Great and the immediate successors to his vast conquests. An essential feature in it, whether in the sieges of inland fortresses or those on the seaboard, was to cut off all communication between the place and the exterior by hemming it in by sea and land with stationary forces, covered themselves by lines of intrenchments strengthened by towers, and, in the case of sea-coast places, also by fleets, from all assaults both from without and from the place invested. Having selected the portions of the place on which the attack was to be directed, a second line was formed parallel to the first, which was covered, and constructed of timber and wicker-work, and secured with raw hides to prevent its being set on fire. From this sheltered position, which served also the purpose of a lodging for the besiegers, the besieged were annoyed with missiles thrown from all the artillery known in that day, consisting of the ordinary bow, the cross-bow, and the various machines for projecting heavy stones and other projectiles. The defense was mostly of a passive character; the besieged trusting mainly to the strength of their defenses, under cover of which they resorted to all the means used by the besiegers for assailing the latter when they came within reach of their missiles; using cranes and other devices to seize upon the implements planted at the foot of the wall, and carrying out galleries of countermines to overwhelm the artificial mounds and their towers. The Romans evinced their decided military aptitude not only in the employment of the ordinary systematic methods of the attack and defense of fortified places, but in their application of the cardinal principle of mutual defensive relations between the parts of a fortified position, obtained by advanced and retired portions of the enceinte, and also in the adaptation of intrenchments to the natural features of the site, as shown in the fortifications of some of the permanent frontier camps of their military colonies. These principles have also been noticed in some of the fortified positions of India, which consist of a mural enceinte with the earthen ramparts flanked by round towers, and of round towers in advance of the enceinte connected with it by caponieres.

The remains of the structures raised for defensive purposes during the prosperous days of the Empire were probably the sole means of protection afforded to the inhabitants of the towns that still maintained a nucleus of population, until the rise of the Western Empire under Charlemagne; and it was the necessity felt by this conqueror not only of securing his conquests, but of checking the irruptions of the barbarous tribes along his extended frontier, which led him to erect *têtes-de-pont* on the frontier rivers, and a line of strong towers, for garrisons of a few men, upon the most inaccessible and prominent points of this frontier; the latter being a means which was subsequently resorted to for a like purpose in the Spanish Peninsula. Henry I. of Germany introduced a more important and more systematic addition to these permanent frontier defenses by surrounding the frontier towns and villages, occupied by military colonists, with walls and ditches, to secure them from such attacks as they might be exposed to, and subsequently adding a second line of strongholds within the frontier, by which an irruption through the frontier line might still be checked. During the general disorganization of States under the feudal system, the free cities, which depended for their defense on the burghers composing the different crafts, every individual who could maintain a few retainers in his pay, and the Clergy, even, resorted—each according to their separate views—to such means of defense as would best secure them from the attacks of others in a like condition, and would enable them to carry out that system of pillage which had become general among the nobles and other military chieftains. From this state of society sprang up those castles placed in the most inaccessible positions on the lines of communication which the little inland commerce that was still carried on was obliged to traverse. These were provided with every possible device for an obstinate passive defense, being surrounded by a wide and deep ditch, or moat, over which a drawbridge was the only communication to the main entrance, which was flanked by towers on the exterior, and closed with massive doors; the tortuous passage which led from them to the interior of the castle being further secured by a grated portcullis, which could be let drop at a moment's notice, to arrest a sudden assault. To these means were often joined, besides the ordinary measures of loop-holes and machicoulis in the walls and towers for annoying the assailant, a high interior tower, termed a keep, or donjon, which, commanding the exterior defenses, was also a watch-tower over the adjacent country. The keep, which was the last defensible point, was in some cases provided with a secret subterranean passage, having its outlet in some distant concealed spot, through which succor could be introduced into the beleaguered castle, and, in the last extremity, the garrison find safety in a stealthy flight. The fortifications of towns partook of the same characteristics as those of castles. From the old custom of assigning to the different burgher crafts, each of which had an independent military organization, the exclusive guardianship of portions of the enceinte, as well as their erection and repairs, great diversity, and frequently a whimsicality, in the defensive arrangements was the natural result; the evidence of which still exists in the remains of the walls of some of the old Continental cities. The art, for the most part, was practiced by ambulatory engineers, who, like the secret orders by whom the bridges and churches of the same period were built, offered their services wherever they were wanted. Many ideas were also introduced from the East by the Crusaders, as exhibited in the fortifications of castles and cities belonging to the Templars and other religious military orders.

With the invention of gunpowder and its application to military purposes, a gradual revolution took place in the general forms and details of fortification. It was soon seen that naked walls alone did not offer either suitable conveniences for the new military machines, or sufficient protection against the projectiles thrown from them. This led to the introduction of earthen ramparts and parapets, which were placed against the walls and suitably arranged to meet the exigencies of the moment. The art received something like a scientific basis about this time in Italy, from which the names and forms of most of the elements of fortification now in use are derived. The Italian engineers, like their predecessors, went from State to State to offer their services wherever they were needed, and in this way disseminated the principles of their School throughout Europe. It was at this epoch that the bastioned form of fortification first appeared, but the precise date and the author of the invention are both unknown. With its introduction the importance of separating the parts of a line of fortification into advanced and retired parts, the latter flanking and defending the former, seems to have been recognized as an essential principle of the art. With these changes in the form of the enceinte, the art was gradually improved by the addition of the outworks to increase the amount of cross- and flank-fire; the introduction of bomb-proof shelters for the troops and other purposes; the substitution of earthen for stone parapets; and the attempt to conceal the scarp-walls from the enemy's batteries by decreasing the command and deepening the ditches of the enceinte. By these gradual changes stone walls, which in the old fortifications were the essential defensive features, came at length to be regarded in their true character, simply as passive obstacles to an open assault by escalade. The property of earthen parapets, of resisting without material loss of strength the long-continued fire of the assailant's heaviest guns, showed that the same defensive means were applicable both to work of a permanent and of a temporary character; and were equally available for the purposes of the assailant and the assailed. The measures for the attack and the defense of positions were thus reduced to the same general principles, differing only in the forms and dimensions of the elementary parts, as circumstances seemed to demand. From the discussions of and the variations made in the bastioned system by engineers of this period, there arose *four* distinct Schools of Fortification—the Italian, Dutch, French, and Spanish, all belonging to this system. As above stated, the first employment of bastions as they now exist was made by the Italian engineers, and, as far as has been ascertained, towards the close of the fifteenth or the commencement of the sixteenth century. To whom the credit of their invention is due is not known. In the earlier fronts of the Italian School the bastions are very small, and they are connected by curtains varying from 250 to 500 yards in length. The bastion flanks, which were perpendicular to the curtains, were divided into two portions; that next to the curtain, which was one third of the entire flank, was thrown back and covered by the portion in advance, which thus formed what received the name of the orillon. The lower part of the retired portion was casemated for cannon; and behind this, and separated from it by a dry ditch, rose a second flank, having the same command as the other parts of the enceinte parapet. In some cases a small and very obtuse bastion was erected at the middle of long curtains. The defects of these early fronts were soon felt, and a more complicated but improved method adopted, in which the bastions were enlarged and the curtains diminished. The retired flanks were still retained, but the orillon instead of being angular was rounded. To these improvements, cavaliers were sometimes added to the bastions, which in those cases were made without retired flanks; or placed on the curtains, when, from the configuration of the site, some portion of the ground within cannon-range could not be swept from the enceinte parapet. The covered-way was introduced and became an integral part of the front; and a small demi-lune or ravelin was placed in advance of the enceinte ditch, forming a *tête-de pont* to cover the communication, at the middle of the curtain across the main ditch, between the enceinte and the exterior.

The Dutch School took its rise in the political necessities of the times in which the national spirit was aroused to throw off an onerous foreign yoke. The aquatic character of the country, and the want of time and pecuniary means, led to those expedients of defense which are never wanting under like circumstances. The deficiency of earth led to the formation of low parapets for the main enceinte and wide ditches filled with water. The main enceinte was usually preceded by a second one with a very low parapet to sweep the surface of the wet ditch; and this second enceinte was separated from the first by a dry ditch, which favored sorties, and which was provided with all the means, as palisades, tambours, and block-houses, for offensive returns and surprises. The second enceinte was generally covered from an exterior command by a glacis in advance of the main ditch. The covered-way between the glacis and the ditches was, to a great extent, deprived of its essential offensive feature by an exterior wet ditch made at the foot of the glacis and inclosing it, over which communication with the exterior was kept open by temporary bridges. The works were usually very much multiplied and their combination complicated; features the less objectionable where their defense chiefly rested upon the inhabitants who had become familiar with all their turnings, and as offering obscurity of design to an assailant who might force his way into them. The whole of the defensive measures of this School seem to have had solely for their object a strictly passive resistance. With this view long lines of intrenchments, supported from distance to distance by forts, connected their frontier towns and villages, affording a sufficient obstacle to marauding expeditions, and requiring the efforts of a strong force to break through them. What may be termed the characteristics of the French School are to be seen rather in the method of Cormontaigne than in the practice of Vauban, although his authority has exercised a preponderating influence throughout Europe, and is still appealed to, in all great problems of the art, by each side in polemical disputes. This School is characterized by the retention of the profile of the Italian School, combined with the outworks of the Dutch, and a systematic arrangement of all the parts. The French have evinced in this, as in all the other arts, that spirit of systematic combination which forms one of their most striking national traits. From the existing fortifications of Spain the influence of the Italian School may be traced, but modified by national characteristics. The works seem organized more for a purely passive defense; the covered-way, that essential outwork to an active defense, being in many cases omitted, the means of annoying the besiegers by fires being greatly multiplied, and the outworks generally being arranged with a view to a purely passive defense. Besides this, the dimensions of the profile and height of scarp were increased as a greater security against escalade; interior retrenchments were multiplied, sometimes inclosing a bomb-proof keep to render the defense more obstinate. The Spaniards, although resorting but little to sorties, show great skill and pertinacity in the defense of breaches, and in availing themselves of all obstructions for prolonging resistance.

The combinations adopted in fixing the defensive relations, and the proportions of the various parts of the bastioned system, produced a great many methods of fortification. These differ so little in plan from those that characterize the four Schools just named, that they may all be placed under the head of one or the other of these classes. It has been observed how the natural features of the country, like Holland, and the national characteristics of the people, like the Spanish, have modified the plan and profile of their works. This is particularly true in Sweden, and partly so in Germany. We may then form two other Schools based on these peculiarities —that of Sweden and that of Germany. The part played by Sweden upon the theater of Europe, under her two celebrated Monarchs, Gustavus Adolphus and Charles XII., served to develop in this nation every branch of the military art, and produced a number of distinguished Generals and Engineers, who combined, with the practice of their profession, a study of its theory. Among the engineers of this School, Virgin holds the first place. The climate and the nautical habits of the country seem to have led to land-defenses analogous to those of ships, as shown in the uses of casemated batteries in several tiers, both for sea-coast and inland fortifications. In this School the bastioned system seems to have been generally adopted for the enceinte, great attention being paid to covering the faces of the works from enfilading fire; in providing casemates having reverse views on the besieger's works; and particularly in so arranging the interior dispositions that each part should not only contribute to the defense of the others, but be capable of an independent resistance. These dispositions necessarily led to great complication and multiplicity of works, as shown in the writings of Virgin. The Germans reckon a number of original writers on fortification, among the most noted of whom are the celebrated painter Albert Dürer, Daniel Speckle, and Rimpler. In the propositions of these writers are to be found the influence which the Italian School naturally exercised throughout civilized Europe, and the germs of many of the views held by the German School of the present day; which last seem, however, to have been taken more immediately from the propositions of Montalembert and Carnot.

The introduction of cannon, although it led to important changes in the measures both of the attack and defense, still did not, for a considerable period, bring about any very decisive results in the length of sieges. The means which it afforded the defense of reaching the besiegers at a distance, and of destroying all the methods of approaching and annoying the place which had hitherto been used, led to the substitution of the ordinary trenches of the present day for the wooden galleries and other similar expedients for approaching under cover, and to the erection of batteries at distant points to open breaches in the walls. Lines of circumvallation and countervallation, which formed so prominent a feature previously to this epoch, was the only one which still kept its place, as it has done to a greater or less extent to the present day. For the purpose of effecting an entrance into the place, breaching-batteries were erected opposite the points deemed most favorable. They were placed either on natural elevations of the ground or upon artificial mounds, with the object of attaining the wall to be opened near its foot, and to form a breach of easy ascent. These batteries were enclosed in works of sufficient size and strength to hold garrisons to secure them from sorties. The approaches were made as at present, by zigzags along the capitals of the salients to the counterscarp, where a covered descent was made into the ditch opposite the breach preparatory to its assault. When the wall was not exposed to a distant fire, the besiegers were obliged to carry the covered-way by assault, and establish their breaching-batteries on the crest of the glacis. In carrying forward these works the besiegers were subjected to great losses and delays, owing to the magnitude and the multiplicity of the works they were obliged to complete; to the imperfect character of their artillery and the faulty position of their batteries, by which they were unable to keep under the fire of the place; the want of connection between the separate approaches, and the consequent exposure of the workmen in the trenches to sorties, the troops for their support being too distant in the inclosed works in the rear to give them timely succor; besides which, as these inclosed works naturally became the chief objects for the fire of the besieged, this agglomeration of troops in them added materially to the losses of the besiegers. Owing to these imperfections in the measures of attack, the besieged were able to make a vigorous and prolonged defense; and sieges became the most important military operations of this period, in which Captains of the greatest celebrity sought for opportunities of distinction.

But little deviation was made in the methods just described until Vauban appeared upon the scene. Previously to him, Monthic, a distinguished French General and Engineer of his day, had introduced short branches of trenches, which were run out from the angles of the zigzags, to post a few troops for the immediate protection of the workmen; but these were found to be very insufficient in repelling sorties of any strength. The event which seems to have had the greatest influence on the subsequent progress of both the attack and defense was the memorable siege of Candia, in which volunteers from all parts of Europe engaged, and who, after its close, disseminated throughout their respective countries the results of the experience they had there acquired. Whether the idea of the parallels, now in use in the attack, originated there, or with Vauban, this eminent man was the first to establish them in a systematic manner, and to demonstrate by experience their controlling importance in repressing sorties. The introduction of this important element in the attack; the concentration of the fire of batteries, by giving them enfilading positions; the invention of the ricochet, as the most powerful destructive means against the defenses; the avoidance of open assaults, which, even when successful, are made at a great sacrifice of life, preferring to them the less brilliant but slower method of skill and industry, by which the blood of the soldier is spared, and the end the more surely attained, such are the important services which the attack owes to Vauban, which has given it its present marked superiority over the means of defense, and to which the science and experience of engineers since his day have added nothing of marked importance.

From this brief summary, it will be seen that the art of fortification, in its progress, has kept pace with the measures of the attack; its successive changes having been brought about by changes either in the arms used by the assailant, or by the introduction of some new mode of assault. The same causes must continue to produce the same effects. At no past period has mechanical invention, in its bearing on the military art, been more active than at the present day. The improvement that has already been made in the range and accuracy of aim of both small-arms and cannon, the partial adoption of wrought-iron and steel for floating batteries and sea-coast defenses, point to the commencement of another epoch in the Engineer's art. The great improvement in cannon will give to the assailant a still wider range in the selection of positions for his batteries, and will thus increase the difficulties of the engineer in adapting his works to the site, and in giving adequate shelter to the garrison and armament. Whilst the defense will be to this extent weakened, the approaches of the besieger will be rendered more perilous and more difficult from the greater range and accuracy of small-arms. Upon the chief defects and wants of the art there exists but slight divergence of opinion among engineers generally; not so with respect to the remedy; opposite opinions being frequently drawn from the same class of facts, and the same authority being frequently cited to sustain opposite views. Whilst each new disputant denounces systematizing and the systems of others, his remedy for the abuse complained of is usually a system of his own, which not unfrequently is but a combination of the *disjecta membra* from those of others. See *Castle*, *Enceinte*, *Field-fortification*, *Permanent Fortification*, and *System of Fortification*.

FORTIFICATION-DRAWING. — The method now in general use, among military engineers, for delineating the plans of permanent fortifications is similar to the one which had been previously employed for representing the natural surface of ground in topographical and hydrographical maps, and which consists in projecting, on a horizontal plane at any assumed level, the bounding lines of the surfaces and also the horizontal lines cut from them by equidistant horizontal planes, the distances of these lines from the assumed plane being expressed *numerically* in terms of some linear measure, as a yard, a foot, etc. The assumed horizontal plane upon which the lines are projected is termed the *plane of comparison* or *plane of reference*, as it is the one to which the distances of all the lines from it are referred, and as it serves to compare these distances with each other and also to determine the relative positions of the lines.

The numbers which express the distances of points and lines from the plane of comparison are termed *references*. The unit in which these distances are expressed is usually the linear foot and its decimal divisions. As the position assumed for the plane of comparison is arbitrary, it may be taken either above or below every point of the surfaces to be projected. In the French military service it is usually taken above, in our own below the surfaces. The latter seems the more natural and is also more convenient, as vertical distances are more habitually estimated from below upwards than in the contrary direction. Each of these methods has the advantage of requiring but one kind of symbol to be used, viz., the numerals expressing the references; whereas, if the plane of comparison were so taken that some of the points or lines projected should lie on one side of it and some on the other, it would be then necessary to use, in connection with the references, the algebraic symbols *plus* or *minus* to designate the points above the plane from those below it. As the distances of all points are estimated from the plane of comparison, the reference of any point or line of this plane will therefore be zero (0.0); that of any point above it is usually expressed in feet; decimal parts of a foot being used whenever the reference is not an entire number. When the reference is a whole number it is written with one decimal place, thus (25.0); and when a broken number with at least two decimal places, thus (3.70), (15.63). In writing the reference the mark used to designate the linear unit is omitted, in order that the numbers expressing references may not be mistaken for those which may be put upon the drawing to express the horizontal distances between points. The references of horizontal lines are written along and upon the projections of these lines. All other references are written as nearly as practicable parallel to the bottom border of the drawing, for the convenience of reading them without having to shift the position of the sheet on which the drawing is made.

This method of representing the projections of objects on one plane alone has given rise to a very useful modification of the one of orthogonal projections on two planes, and has been denominated *one-plane descriptive geometry;* the plane of comparison being the sole plane of projection, and the references taking the place of the usual projections on a vertical plane. By this modification the number of lines to be drawn is less; the graphical constructions simplified; and the relations of the parts are more readily seized upon, as the eye is confined to the examination of one set of projections alone. But the chief advantage of it consists in its application to the delineation of objects, like works of permanent fortification, where, from the great disparity of the horizontal extent covered and the vertical dimensions of the parts, a drawing, made to a scale which would give the horizontal distances with accuracy, could not in most cases render the vertical dimensions with any approach to the same degree of accuracy; or, if made to any scale which would admit of the vertical dimensions being accurately determined, would require an area of drawing surface, to render the horizontal dimensions to the same scale, which would exceed the convenient limits of practice. Taking for example an ordinary scale used for drawing the plans of permanent fortifications of *one inch* to *fifty feet*, or the scale $\frac{1}{600}$, the details of all the bounding surfaces can be determined with accuracy to within the fractional part of a foot, whereas a vertical projection to the same scale would be altogether too small for the same purposes.

For the convenience of numerical calculation, the position of a line, with respect to the plane of reference, is often expressed in terms of the natural tangent of the angle it makes with this plane; but as this angle is the same as that between the line and its projection, its natural tangent can be expressed by the difference of level between any two points of the line, divided by the hoirzontal distance between the points. Now, as the difference of level between any two points of the line is the same as the difference of the references of the points, and the horizontal distance between them is the same as the horizontal projection of the portion of the line between the same points, it follows that the natural tangent of the angle which the line makes with the plane of reference is found *by dividing the difference of the references of the points by the distance in horizontal projection between them.* The vulgar fraction which expresses this tangent is known as the *inclination* or *declivity* of the line. Thus the fraction $\frac{1}{6}$ would express that the horizontal distance between any two points is six times the vertical distance, or difference of their references; the fraction $\frac{2}{3}$, that the vertical distance between any two points is two thirds the horizontal distance; *the denominator of the fraction*, in all cases, *representing the number of parts in horizontal projection, and the numerator the corresponding number of parts in vertical distance.* When the position of a line is designated in this way, it is said to be a line whose inclination or declivity is one sixth, two thirds, ten on one, etc., or simply *a line of one sixth*, etc.

Knowing the declivity of a line, the difference of reference of any two of its points, the projections of which are given, will be found by multiplying the horizontal distance between them by the fraction which expresses this declivity; in like manner the horizontal distance of any two points will be obtained by dividing the difference of their references by this fraction. To obtain, therefore, the reference of a point of a line, having its projection, the horizontal distance between it and that of some other known point of the line must be determined from the scale of the drawing by which the horizontal distances are measured; this distance expressed in numbers, being multiplied by the fraction which expresses the declivity of the line, will give the difference of reference of the two points; the required reference of the point will be found by subtracting this product from the reference of the known point, if it is higher than the point sought, or by adding if it is lower.

When the projection of a line is divided into equal parts, each of which corresponds to a unit in vertical distance, and the references of the points of division are written, it is termed *the scale of declivity of the line.* In constructing the scale of declivity of any line, the entire references are alone put down; one of the divisions of the equal parts being subdivided into tenths, or hundredths if necessary, so as to give the fractional parts of the references corresponding to any fractional part of an entire division. The true length of any portion of an oblique line between two given points is evidently the hypothenuse of a right-angled triangle of which the other two sides are the difference of reference of the points, and their horizontal distance.

The position of any plane oblique to the plane of reference may be determined either by the projections and references of three of its points; by the projections and declivity of two lines in it oblique to the plane of reference; or by the projection of two or more horizontal lines of the plane with their references. The more usual method of representing a plane is by the projections on the plane of reference of the horizontal lines determined when intersecting it by equidistant horizontal planes. These projections are termed *horizontals of the plane*, those usually being taken the references of which are entire numbers. If in a given plane a line be drawn perpendicular to any horizontal line in it, the projection of this line on the plane of reference will be also perpendicular to the projections of the horizontals. The angle of this line with the plane of reference is evidently the same as that of the given plane with it, and is greater than the angle between any other line drawn in the plane and the plane of reference. This line is, on this account, termed *the line of greatest declivity* of the plane. If the scale of declivity of the line of greatest declivity be constructed, it will alone serve to fix the position of the plane to which it belongs, and to determine the reference of any point of the plane of which the projection is given. For, since the horizontals are perpendicular to the scale of declivity, the point where the horizontal drawn through the given projection of a point in the plane cuts this line will determine upon the scale the reference of the horizontal, and therefore that of the point.

The inclination or declivity of any plane with the plane of reference may be expressed in the same way as the inclination of its line of greatest declivity. Thus *a plane of one fourth, a plane of twenty on one, a plane of two thirds*, express that the natural tangents of the angle between the planes and the plane of reference are respectively represented by the fractions $\frac{1}{4}$, $\frac{20}{1}$, and $\frac{2}{3}$. The horizontal distance between any two horizontal lines in a plane, the angle of which is given, can be found in the same way as the horizontal distance between two points of a line, the inclination of which is given, by dividing the difference of the reference of the two horizontal lines by the fraction representing the declivity of the plane; in like manner the difference of references of any two horizontal lines will be obtained by multiplying their horizontal distance by the same fraction. With the foregoing elements the usual problems of the right line and plane can be readily solved. See *Drawing.*

FORTILAGE.—The name formerly given to a little fort or block-house. The word is now obsolete, as also the word *fortin*, used in the same sense. *Fortlet* is commonly used at present.

FORT MAJOR.—The next officer to the Governor or Commandant in any fortress. He is expected to understand the theory of its defenses and works, and is responsible that the walls are at all times in repair. He is on the Staff, but has to resign his regimental appointment, and receives an addition to his half-pay.

FORWARD.—The word of command given when troops are to resume their march after a temporary interruption.

FOSS—FOSSE.—In fortification, the ditch or moat, either with or without water, the excavation of which has contributed material for the walls of the fort it is designed to protect. The foss is immediately without the wall, and offers a serious obstacle to escalading the defenses.

FOSSANO POWDER.—The "progressive powder of Fossano," made at the Italian powder-mills of Fossano, is of peculiar manufacture. After passing through the first stage of manufacture, and being brought to the condition of *meal-powder*, it is pressed into a cake which has a density of 1.79. The cake is then broken up into irregular grains of about an eighth to a quarter of an inch in thickness. The grains are then mixed with a certain quantity of fine-grain powder, and the whole mass is pressed into a cake which has a density of 1.75. This second cake is then broken up into tolerably regular pieces about $2\frac{1}{8}$ inches square by $1\frac{3}{4}$ inches thick. These grains are therefore composed of a number of small pieces with a higher density placed in a sort of conglomerated powder-material of a lower density, the intention being to produce more gas in a given time, when the powder has been partly burned, than at the commencement of its ignition. This is accomplished by the lighter powder igniting first and producing inequalities or indentations in the grains, when the denser portions will burn with an increasing surface. The Fossano powder has given remarkably high velocities with moderate pressures, and has the great merit of cheapness and simplicity. See *Gunpowder.*

FOSSEWAY.—One of the military Roman roads in England, so called from the ditches on both sides.

FOTHERGILL PROCESS.—This is one of the numerous dry processes in photography which have for their object the preservation of sensitive plates ready for exposure. It is named after the inventor, and consists in the partial removal of the free nitrate of silver which adheres to the collodion film on withdrawing it from the sensitizing bath by washing with water, and the subsequent conversion of the remaining free nitrate of silver into albuminate and chloride of silver by pouring over the plate dilute albumen, containing chloride of ammonium, the excess of albumen being finally washed off by violent agitation with a copious supply of water. The plates being set aside to drain on folds of blotting-paper are, when thoroughly dry, ready for use. See *Photography*.

FOUCADE.—A term formerly and very commonly applied to a small mine. Also written *Fougade*.

FOUGASSES.—Mines are so called when placed at the bottom of small shafts from 9 to 12 feet deep. The powder is lodged in one of the sides of the shaft, and it is fired from a secure spot by means of a powder-hose train, brought up one side of the shaft, and carried in a trough, parallel to the ground, 5 or 6 feet below the surface. When there is no occasion to fear that shells may fall on the part where the trough is laid, it will be sufficient to place it 2 or 2½ feet under the ground. The powder-case and trough should be well pitched, the shaft tamped in the strongest manner, and the earth round about the shaft be dug over, that nothing may indicate to the enemy the position of the fougasse.

The chief difficulty attending the use of fougasses is to explode them at the instant when the enemy is passing over, as any variation in the time of explosion from this instant renders them useless. It is recommended to place an obstacle over them, as an abatis or chevaux-de-frise, so that the fougasses may be exploded while the enemy is occupied in forcing his way over. See *Shell Fougasses* and *Stone Fougasses*.

FOUGETTE.—An Indian sky-rocket, a species of fire-work which is frequently used by the Asiatics. It is made of the hollow tube of the bamboo, of a very large size, filled with the usual composition of rockets. The rod is only a part of the same bamboo, the greater part of which is cut away.

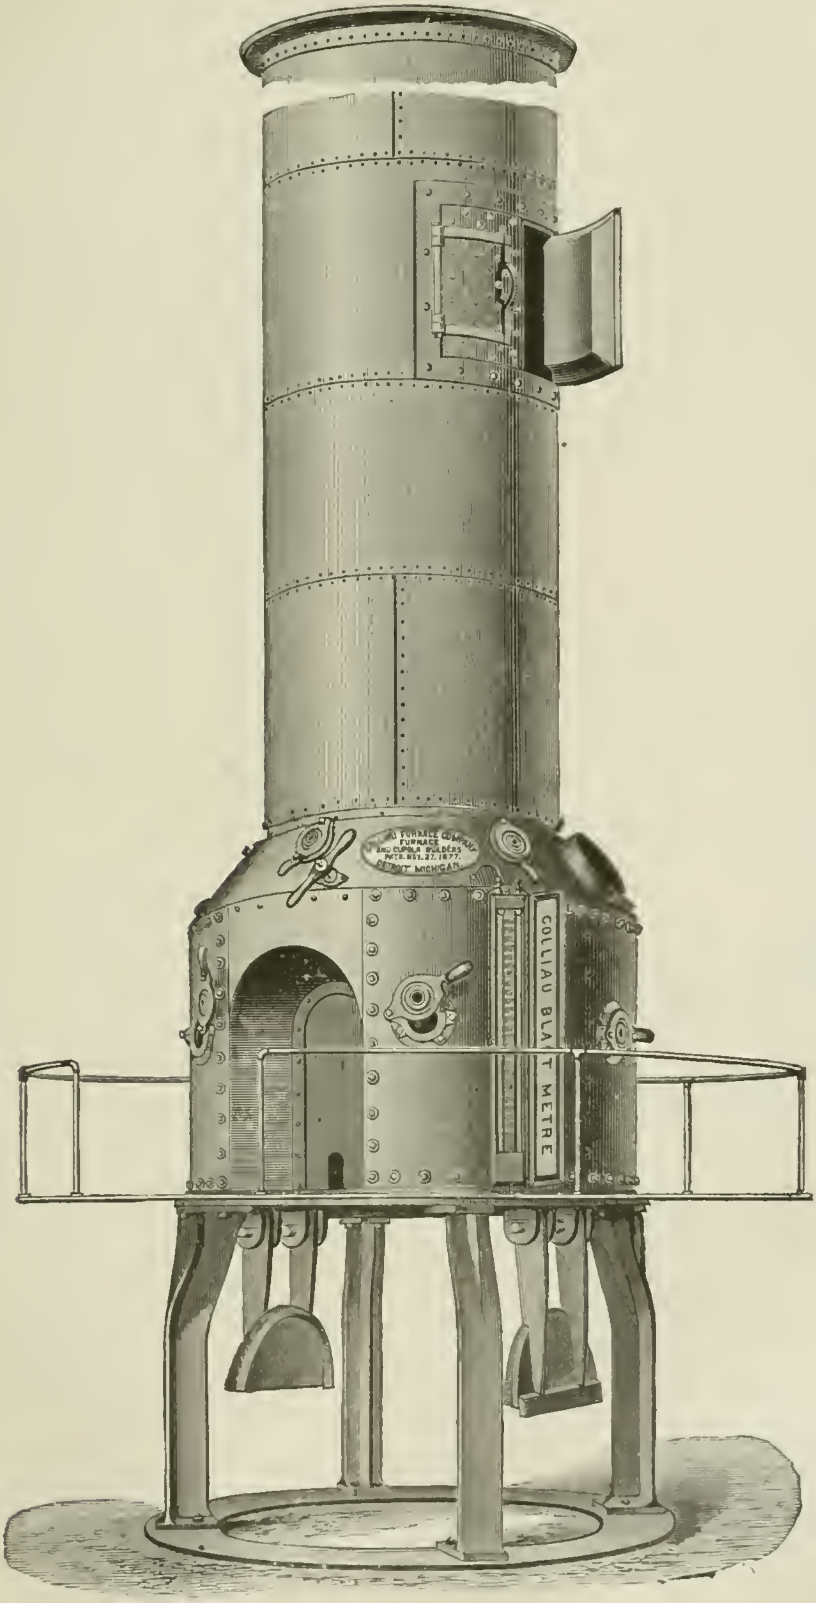
FOUILLER.—In a military sense, to detach small bodies of infantry round the flanks of a column that is marching through a wood, for the purpose of discovering an ambuscade, and of giving timely notice that it may be avoided. The same precaution is necessary when a body of men advance towards or enter a village.

FOULING.—Smoke is a solid product of the explosion in a fine state of division; but at the instant of explosion this product is liquid and a part of it cakes together in the bore and causes *fouling*. Each succeeding round, however, expels a good deal of that which was previously deposited. *Fouling* is more likely to occur in a small-arm than in a large piece of ordnance, and it is best prevented by the use of good powder in the charge and careful sponging. It gradually impairs the accuracy, sometimes makes the breech difficult to open, and increases the recoil, as the resistance to motion of the bullet in the bore becomes greater, and consequently the charge exerts its force for a longer time.

FOUNDATION.—The artificial structure on which the remainder of an edifice rests. The *body* of the foundation is the masonry or timber-work used; the *bed*, the prepared surface on which the body rests. The bed may be a leveled surface of rock, sand, or earth, consolidated by beating or by driving piles into it; if the tops of the piles are bound together by a flooring of timbers—called a grillage—this flooring is deemed the bed of the foundation. Rock is the best foundation, but its bearing power should be tested, and its upper surface should be made normal to the direction of the pressure. To avoid expense, the bearing surface may be left in steps, but the steps should be filled with well-fitted masonry, that there may not be undue settlement upon the filled side, in case the lowest step should be much lower than the highest. Great care should be taken to apportion the load to the supporting power of the foundation; if the latter be found inadequate, the area of the foundation should be increased until the weight distributed to each unit of surface shall be brought within the proper maximum. Engineering science has been severely tested by demands for sure foundations in places where the soil and substrata are by nature yielding, or exposed to the insidious action of running water, or where both evils are united. Except upon solid rock, settlement cannot be avoided. It is enough for the safety of the structure if the settlement can be made uniform in all its parts.

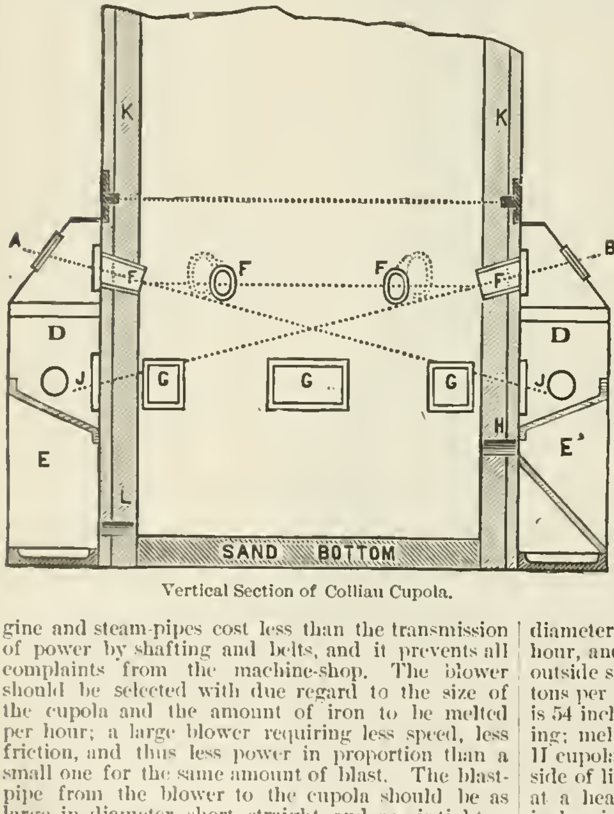
A method of constructing foundations in deep water adopted in late years is called the "pneumatic;" the manner of its application is either that of a "vacuum" or a "plenum," according as the pressure of the air within is below or above the usual pressure of the atmosphere. In either case, an iron cylinder, usually constructed in sections, is lowered into the water until its lower end rests on the bottom, while its upper end extends above the surface. If the vacuum process be used, the cylinder is capped, and an air-pump reduces the pressure of the air within. The weight of the tube with the atmospheric pressure on its head pushes it into the ground, while the water pressing in below the lower end stirs the earth and assists the descent. When descent stops, the air-pump may be reversed, and the water in the pipe will be slowly driven through the earth; a sudden release of the inner pressure will cause a second influx of water, a disturbance of the soil, and a further descent of the tube. If the earth contains bowlders or buried timbers, the movement of the tube may be stopped before reaching the depth desired by the Engineer; or he may wish to remove the interior earth and replace it with masonry, even where the ground is too gravelly to keep out the water. In this case an air-lock is placed upon the top of the tube, air is forced into the interior, driving out the water, and workmen are employed within to excavate the earth, and afterward to lay the masonry. The air-lock is a chamber which serves as a vestibule to the interior, and permits the maintenance of a nearly constant air-pressure within. A man enters the air-lock and closes the door behind him; he then opens communication with the interior of the tube, and when the pressure of air is equalized in the two spaces he passes within.

FOUNDRY.—The principal points to be considered in the erection of a foundry are the proper arrangement of plants for the economical handling of the iron and fuel, and the castings when made. The ground should be well drained, and if in the proximity of water, the lower floor should be several feet above the highest level of the water. The foundry-floor is filled with molding-sand, from five to ten feet deep. Sometimes it is necessary to have pits, made of boiler-iron, set in the ground, twenty to thirty feet deep, as in the car-wheel foundries, for the annealing process. The main building, used for the molding-room, should be at least twenty feet high in the walls, and should be well lighted, especially in the roof, by running a large sky-light the entire length of the building, and so arranged as to be easily opened for ventilation. Additional rooms should be provided for storing and preparing the materials of the molds, such as grinding and sifting the sand, loam, sea-coal, coke, plumbago and the charcoal, and likewise for cleaning the castings and milling them. There should also be a workshop for making patterns, and large ovens for drying the cores. The molding-room should have an area proportionate to the amount of work and kind of castings to be made. For example, the Detroit Car-wheel Company, Detroit, Mich., have a molding-floor with an area of about 10,000 square feet. They cast 360 wheels per day, melting 100 tons of iron. Barney & Smith, Dayton, Ohio, floor-area 6000 square feet, melt 50 tons of iron, making 170 car-wheels per day. Louisville Car-wheel Company, floor-area 9000 square feet, melt 50 tons of iron, making 170 car-wheels per day. Union Foundry and Pullman Car-wheel Works, Pullman, Ill. melt 125 tons of iron per day, making 160 wheels, besides other castings. Area of floor,



The Victor Colliau Cupola.—For Foundry Use.

50,000 square feet. Walter A. Wood Harvester Company, Hoosick Falls, N. Y., melt 40 tons of reaper and mower castings per day. Area of floor, 18,000 square feet. A stove-foundry requires a very large floor-area. The cupolas should be placed as near the center of the building as possible, so as to equalize the distance for carrying the melted iron from the cupola to the molds. This is done very economically, for small castings, in ladles on wheels, running on rails, distributing the iron to small hand-ladles at each separate floor. For heavy castings large cranes are used, for lifting and moving molds and castings, and conveying the melted metal in large ladles. The cupolas should be outside of the molding-room, in a separate building, containing the cupola loading-floor, elevator (if inclined plane is not used), and a mill for cleaning the cupola-droppings. The height of the charging-doors above the bottom plate should be not less than 12 feet; 14 to 16 feet is better. It is a good plan to provide a separate steam-engine to run the blower. This is more economical even in the first construction, as the engine and steam-pipes cost less than the transmission of power by shafting and belts, and it prevents all complaints from the machine-shop. The blower should be selected with due regard to the size of the cupola and the amount of iron to be melted per hour; a large blower requiring less speed, less friction, and thus less power in proportion than a small one for the same amount of blast. The blast-pipe from the blower to the cupola should be as large in diameter, short, straight, and as air-tight as possible. Avoid all bends if possible; if not, make them as long and easy as circumstances permit.



Vertical Section of Colliau Cupola.

The foundry is the basis or starting-point of all machinery and heavy guns, and bad castings spoil the work. The foundry should receive as much, if not more, care and study as the machine-shop, and the best cupola should be used. The records of the Colliau cupola show the most economy in fuel and iron, the greatest rapidity in fusion, and the largest amount of iron melted in a given time and size, as well as the greatest quantity of iron melted at a heat in one cupola without clogging. This cupola is represented complete in the engraving on page 701. The accompanying drawing represents a vertical section. D D is the air-box, G G the lower tuyeres, F F the upper tuyeres. A B is the line of horizontal section, shown below the vertical section. E is the arch over the tap-hole, L. E′ is the arch over the slag-hole, H. The line from F to J shows the inclination of the upper tuyeres, F F. K is the inside brick lining. The peculiar features of the Colliau cupola are the proportions and arrangements of the upper and lower tuyeres. The six lower tuyeres are rectangular and are intended to furnish the air necessary to the combustion of the fuel. They are generally left open during the fusion; but as they are provided with gates inside the air-box, they can be shut more or less during the working, to direct the blast more on one side than the other if necessary, or may be closed altogether (in case of accident to the blower). The six upper tuyeres are round, and point downwards. They are arranged to alternate with the lower tuyeres. Their inclination is proportionate to the diameter of the cupola, in such manner that the blast from them will reach the focus of combustion produced by the lower tuyeres. The upper tuyeres are closed when the blast is turned on, and opened when the iron shows at the tap-hole, and the cupola plugged up to accumulate the first draught of iron. This is accomplished by moving the lever-handle which is shown on the top of the air-box in the figure. The opening of these tuyeres produces a downward blast of air (on the principle of a blow-pipe), and furnishes the oxygen necessary to the combustion of the hydrocarbon gas, which, without it, would be thrown off by the imperfect combustion of the fuel at the level of the lower tuyeres. This combined blast produces a melting-point about 18 inches above the upper tuyeres, and nowhere else, concentrating the heat in the smallest possible compass, so that the metal in fusion has less space to traverse while exposed to the oxidizing influence of the blast, thereby insuring tougher castings and more perfect combustion of the inflammable gases (with corresponding economy of fuel), which is contrary to the usual practice of spreading the blast as much as is possible. In the practical use of this cupola there is no flame at the loading-doors, and no throwing off of combustible gases, carbonic-acid gas (the only product of perfect combustion) alone escaping; little or no flame being seen at the top of the stack until the iron is about all melted. This cupola melts more iron per hour in proportion to its size than any other. B cupola is 73 inches outside diameter of shell, 58 inches diameter inside of lining; melts 12 to 15 tons per hour, and 100 tons at a heat. D cupola is 64 inches outside shell, 49 inches inside of lining; melts 8 to 10 tons per hour, and 50 to 60 tons at a heat. F cupola is 54 inches outside of shell, 42 inches inside of lining; melts 5 to 6 tons per hour, and 40 tons at a heat. H cupola is 47 inches outside of shell, 36 inches inside of lining; melts 4 to 5 tons per hour, and 30 tons at a heat. J cupola is 43 inches outside shell, 32 inches inside of lining; melts 3 to 4 tons per hour, and 20 tons at a heat. L cupola is 35 inches outside of shell, 25 inches inside lining; melts ½ to 1 ton per hour, and 4 to 5 tons at a heat. Meltings of 10 to 12 pounds of iron to 1 pound of fuel are obtained in this cupola, according to quantity of metal melted at a heat. One of the results of the Colliau cupola is a decrease of time in melting as the operation advances, that is to say, a better working of the cupola at the end of the operation than at the beginning; this is the reverse of what generally occurs in cupolas. See *Iron*.

FOUR.—A place of confinement in Paris to which vagabonds and persons who could not give any satisfactory account of themselves were committed; and when once shut up had their names registered, and were enlisted for the old French Government. These Fours added annually 2000 men at least to the King's regular army; and by which means the capital was relieved of a multitude of thieves, pickpockets, etc.

FOURAGE.—A term used figuratively in artillery, to signify hay, straw, or anything else of a vegetable growth which is used to ram into the bore of a cannon for the purpose of cleansing it.

FOURGON.—1. A tumbrel or ammunition-wagon. 2. A French baggage-vehicle, much used in the field.

FOURIER.—A Quartermaster belonging to a cavalry or infantry regiment. In France there were *Fouriers Majors* who composed a portion of the Cavalry Staff. *Sergeant Fourier* and *Corporal Fourier* answer to our Quartermaster Sergeant.

FOURNIMENT.—A horn formerly in use, which held about one pound of gunpowder, to prime cannon. It was likewise used by cavalry and infantry soldiers, who slung it across their shoulders. The artillerists kept it in a belt.

FOURQUINE.—A forked rest, furnished at its extremity with a point or spikes to fix it steadily in the ground. The musket was at first very considerably heavier than the arquebuse, and it was necessary to discharge it from a rest.

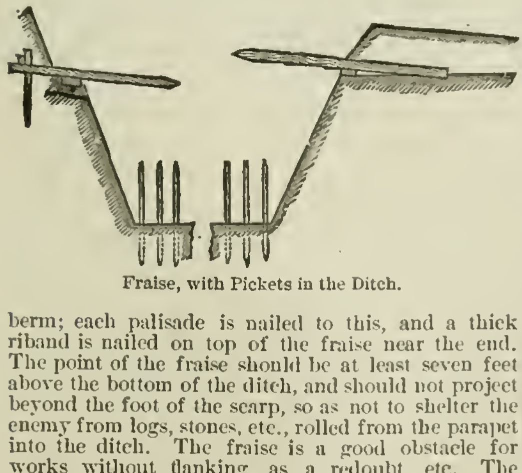
FOWKE'S PONTON.—This ponton is formed of a wooden skeleton, over which is strained strong canvas rendered water-proof. It can be used as a boat and is water-tight. It is readily transported and has a great buoyancy.

FOWLING-PIECE.—A light gun for shooting birds. In constructing the barrels of this sporting-weapon, the maker endeavors to secure the greatest possible lightness, but without detracting from the necessary strength. Formerly wrought-iron only was used, but cast-steel is now very generally preferred. The breech-loading principle has been introduced to a great extent, but many sportsmen are still in favor of the muzzle-loader. The manufacture of the best specimens of fowling-pieces demands a very high degree of mechanical skill.

FOX.—An early and common name given to the old English broadsword.

FRAISER.—To plait, knead, or to drill. In a military sense, to fraise or fence; as, *fraiser un battalion*, to fraise all the infantrymen with pikes, to oppose the irruption of cavalry, should it charge them in a plain. At present it means to secure a battalion by opposing bayonets obliquely forward, or crosswise in such a manner as to render it impossible for horsemen to act against it.

FRAISES.—These obstacles are formed of palisades, placed in juxtaposition, either horizontally or slightly inclined. The best position for a fraise is on the berm, or a little below it, so as to be covered by the counterscarp-crest. The part of the fraise under the parapet is termed the *tail*, and is about five feet long. To make a fraise, a horizontal piece of a four-inch scantling, termed a *cushion*, is first laid parallel to the

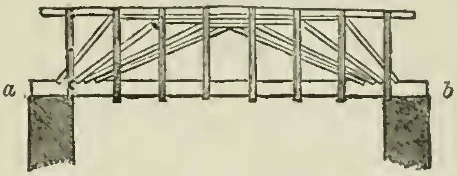


Fraise, with Pickets in the Ditch.

berm; each palisade is nailed to this, and a thick riband is nailed on top of the fraise near the end. The point of the fraise should be at least seven feet above the bottom of the ditch, and should not project beyond the foot of the scarp, so as not to shelter the enemy from logs, stones, etc., rolled from the parapet into the ditch. The fraise is a good obstacle for works without flanking, as a redoubt, etc. The drawing shows the construction of the fraise, also the location of small pickets in the ditch. See *Accessory Means of Defense*.

FRAMEA.—A lance employed by the Franks. The entire head is of one piece, in which the end of the shaft is inserted and riveted.

FRAME-BRIDGE. — A bridge formed of timbers framed together in such a manner as to obtain the greatest possible amount of strength with a given quantity of material. The fundamental principle upon which all such construction is based is that the timbers shall be so arranged that the weight put upon them shall exert a pulling or a crushing strain, instead of a transverse strain, and, if possible, that the greatest strain shall act as a direct pull in the direction of the fibers of the wood. The construction of a frame-bridge is very similar to that of a roof, excepting that in the bridge a considerable outward thrust upon the abutments is generally permissible, while the walls of a house will not stand this; and that for the bridge a nearly level way on the top is desirable, while for a roof a steep incline is not objectionable, or is even desirable. The celebrated frame-bridge of Schaffhausen, constructed in 1757 by Grubenmann, a village carpenter, was built exactly in the manner of a roof, with the horizontal pathway superadded. It was composed of two arches, one 193 feet, the other 172 feet span. It was merely laid upon the piers, and did not abut against them to exert any outward thrust, as will be noticed in the drawing. The weight upon the bridge is transmitted



Bridge of Schaffhausen.

by the oblique beams, which by analogy we may call *rafters*, to the tie-beam *ab*, where it exerts a horizontal pulling strain. These rafters are framed into the tie-beam so as to abut firmly against it in the same manner as roof-rafters (see *Roof*). This kind of frame-bridge is very common in Switzerland, where timber-bridges abound; and it has doubtless originated from the fact that most of the bridges have been built by the local carpenters, who are accustomed to the construction of roofs of considerable span for the commodious square-built wooden cottages with overhanging roofs, so common in that country. Frame-bridges of more complex structure are sometimes built; in some of these the timbers are framed so as to present an arched form. In these cases the structure is very similar to those described and noticed under Centering. The serious defect of all such bridges is their liability to decay from exposure to moisture, etc., especially at the joints, where water is apt to lodge and remain, from want of free circulation of air to evaporate it. In the bridge of Schaffhausen above described, it was found that when it had stood but twenty-six years, the oak beams, where they rested upon the masonry at *a* and *b*, were rotted, and the frames began to settle. This was remedied by a carpenter named Spengler, who raised the whole structure upon piles by means of screw-jacks, and so replaced the decayed wood. Means should be adopted to admit the free circulation of air in those parts where the timber rests upon the masonry, and to prevent water from settling in the timber joints. The covered bridges of Lucerne and other parts of Switzerland are well known as objects of special interest to tourists, who usually imagine that the roofs are constructed for the comfort of travelers, but their main object is the preservation of the bridge.

FRANCHES.—Bodies of men detached and separated from the rest of the army, having each a Chief or a Commandant. They consisted chiefly of dragoons, hussars, etc., and their peculiar duty was to make irruptions into an enemy's country. They may not improperly be called Land-pirates, as their chief occupation was to harass and plunder the enemy and his adherents, in whatever manner they could, without paying any regard to military forms. The persons who composed these corps were termed partisans. They always accompanied the main army in time of war, and were distributed among the different garrisons in France during peace. They were common to every power in Europe. The Pandours and Hulans were of this description. They were the worst afflictions of war; and generally as fatal to their friends as to their enemies.

FRANCISQUE. — A battle-axe generally in use among the Franks. It was either used as a hatchet, or was hurled at the head or at the shield of the enemy. It was made under several varieties of form; and its blows if properly aimed took violent effect.

FRANC-TIREURS.—Bands of French soldiers that sprang into existence during the progress of the Franco-Prussian War (1870–1871). They did not form a part of the regular army, and at first their military organization was very imperfect; but this defect was afterwards in some measure remedied. They exercised a species of guerrilla warfare, attacking small detachments of the enemy, as also single travelers, baggage-trains, etc., their attacks being very often characterized by those savageries incident to this mode of warfare. They consisted mostly of the country population; but their birth, education, clothing, arms, age, and even their aim, were almost in every case different. At first they were not recognized by the Germans as having any military standing at all, and when seized they were shot; but after a time, when they received a better organization, and co-operated with the regular French army, such recognition was accorded them. The name was also applied to French soldiers, during the Crimean War, who were stationed as sharp-shooters, and to certain corps of light infantry in the republican wars.

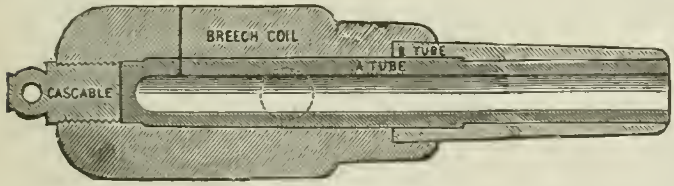
FRANKING LETTERS. — In the United States, established as a system before the adoption of the Federal Constitution, and continued with various modifications until the last day of June, 1873. At first granted only on letters of Revolutionary soldiers who were in actual service, its privilege was afterwards extended to the President, the Heads of Departments, the Chiefs of Bureaus, and certain Clerks designated by the Postmaster General. Public documents were also sent free. It was further extended to Senators and Congressmen for matter addressed by or to them, with certain limitations, before and after the sessions of Congress; Postmasters could *frank* official correspondence; newspapers were exchanged free, and petitions to Congress were sent free, but the weight of packages was limited to 4 ounces each. A further extension included the exchanges of the Smithsonian Institution, medals, and testimonials granted to soldiers. After July 1, 1873, the franking system was in part set aside, and an allowance of stamps was made to the various Departments to cover the expense of correspondence and of the transmission of reports and documents.

In England, on the introduction of the uniform penny-postage on all inland letters in 1840, the privilege formerly enjoyed by Peers and Members of the House of Commons, and many official persons, of *franking* was abolished. The privilege was claimed by the House of Commons in 1660, when the Post-office was first legally established, but it was afterwards dropped upon a private assurance from the Crown that it should be allowed to members. The Postmaster General accordingly constantly issued a warrant directing the allowance, till the privilege was expressly conferred by statute. In the days of *franking*, each Member of either House of Parliament was entitled to send ten letters every day, not exceeding an ounce in weight each, to any place in the United Kingdom, and to receive fifteen, free. As it was not necessary that the letter should be either written by or to the privileged person, the privilege was greatly abused; and most persons whose memories reach back to the period when it existed will remember family arrangements for taking advantage of it, by which the whole correspondence of the kindred, connections, and even the intimate acquaintances of a Peer, or a Member of Parliament, was in general carried on duty free. Up to the passing of the last-mentioned statute, all that was requisite was that the Member should write his name or title on the corner of the letter. From this time, however, till the abolition of the privilege, it was required that the whole address should be written by the Member; that he should add not only his name, but the name of the post-town, and the day of the month; and what was most troublesome of all, that the letter should be posted on the day on which it was written, or the following day, and in a post-town within twenty miles of which the person *franking* was then actually resident. By this regulation the kindly custom of giving franks to friends, or leaving them with them for future use, was rudely interfered with, and the public mind reconciled to the final abolition of what many regarded as a time-honored abuse. See *Official Envelopes*.

FRANKLIN MAGAZINE-GUN.—This gun belongs to that system in which a fixed chamber is closed by a bolt by direct action, and in which the lock is concealed. The receiver has a vertical slot cut entirely through it for the purpose of receiving cartridges from above and affording egress to the empty shells below. It has also a longitudinal slot through which the handle on the breech-bolt slides, with a side-cut at the front end of the slot for the reception of the handle when the bolt is locked. The breech-bolt is composed of three parts, viz., the locking-tube, the bolt-head, and the cocking-piece. To the latter of these the firing-pin, which extends the whole length of the breech-bolt, is secured by a screw. The bolt-head, which supports the cartridge at the instant of fire, is secured to the locking-tube by a pin at right angles to its axis. The firing-pin spring, which is held between the shoulder on the front of the firing-pin and that at the bottom of the locking-tube, serves by its tension to hold in contact the locking-tube and cocking-piece. By means of the spiral surfaces of a projection on the cocking-piece, and a corresponding recess on the locking-tube, the cocking-piece is cammed back, withdrawing the point of the firing-pin within the face of the bolt-head when the piece is unlocked. Accidental explosions are thus avoided in closing the bolt. The form of the cut in the receiver is such as to cam back the handle, and with it the bolt, during the unlocking, starting the empty shell. This is a necessary feature of all bolt guns which are intended to fire copper-case cartridges. The breech-bolt is prevented from being pulled completely out by the nose of the sear striking on the bolt-head. The magazine, which is a metallic tube, lies on top of the barrel. The magazine stop-spring is fastened at its rear to a lever, and its front is inclined to the axis of the receiver. When the handle is turned so as to unlock the breech bolt, a lever one extremity of which enters a groove, while the other is connected with the magazine stop-spring and its lever, is so moved as to cause the stop-spring to move forward, when its inclined front springs through an opening in the side of the receiver and partially covers the mouth of the magazine, preventing escape of cartridges. When the breech-bolt is returned to its locking position the stop-spring is returned to its first position by means of a spring operating its lever; at the same time the inclined face of the stop-spring bearing on the side of the cut in the receiver is pressed out of the way, and a cartridge issues from the magazine into the space above the breech-bolt. It follows, therefore, that a cartridge always occupies the space above the breech-bolt when the piece is locked, provided the magazine has been previously filled. When the bolt is withdrawn, this cartridge, under the influence of gravity alone, falls into a position in line with the axis of the bore. The bullet is supported by a shelf in rear of the chamber. The base of the cartridge is prevented from falling below the line of the axis of the bore by the shape of the slot in the receiver, which is only wide enough for the shell to fall through when its head is behind the extractor. This condition only obtains when the shell is being withdrawn. When the bolt is returned the cartridge is forced into the chamber and another one enters the space above the breech-bolt. A lid covers the opening at the top of the receiver. A catch serves to keep the lid closed except when the breech-bolt is unlocked. If the lid be raised during that time, a shoulder on its interior bearing against a lever prevents the stop-spring returning to its original position. The lid remaining open, the piece may be loaded and fired as a single-loader. No ejector is required with this gun, gravity again being called on to effect the fall of the empty shell through the opening to the ground. As a magazine-gun, three motions are necessary to operate it, viz., opened, closed, fired. As a single-loader, four motions are necessary, viz., opened, loaded, closed, fired. This gun carries ten cartridges in the magazine, one in the space above the breech-bolt, and one in the chamber. See *Magazine-gun*.

FRANKS.—The name assumed by a Confederation of German tribes that appeared on the Lower Rhine in the third century, and afterwards overthrew the Roman dominion in Gaul. It was only the name, however, that was new; the individual tribes composing the Confederation had been known on the Rhine as early as the time of Augustus. The most important of these were the Sigambri, Chamavi, Ampsivarii, Chatti, Chattuarii, and Bructeri of the time of the First Emperors. In the third and fourth centuries hordes of them began to pour through the Low Countries into Gaul, until at last the country became their prey. After the middle of the fourth century they appear divided into two groups, the Salians and the Ripuarians, the former inhabiting Holland and the Low Countries, the latter on both sides of the Rhine as far up as the Main. Each group had its own laws, afterwards committed to writing (*Lex Salica* and *Lex Ripuariorum*). Like the two peoples, these laws differ little even in detail.

FRASER GUN.—This gun is an important modification of the Armstrong gun, from which it differs principally in building up a gun of a few long double and triple coils, instead of several short ones, and a forged breech-piece. The Fraser 9-inch gun is represented in the drawing, where it is readily seen how a great expense is saved by this means of construction, as there is much less surface to be bored and turned. With respect to theory, it may be urged in its favor, in the first place, that a forged breech-piece (which is comparatively expensive, and liable to fly into fragments should the gun burst) is not required with a solid-ended steel barrel and long thick coils, although it is necessary with several short coils to compensate for the longitudinal weakness of their joints. The whole of the wrought-iron, therefore, can be coiled round the barrel, and thus give an extra transverse strength. Again, the trunnion-ring, which had to be shrunk on in the first construction, is welded on to the breech-coil in the Fraser plan, so that there is no fear of slipping. With regard to the second Armstrong principle, although a series of thin coils helps us to distribute the induced strain upon a gun by shrinking on each coil separately, the method is open to the serious objection that it is practically difficult to calculate the respective proportionate amount of extension, and, consequently, the greater the number of pieces in a gun, the more likely that some weakness will exist in the mass, owing to the undue strain on some of its parts. Shrinking on the coils successively was adopted by Sir William Armstrong, as a convenient mode of adhesion, and not on the distribution theory. In the formation of a triple coil, it is generally a manufacturing necessity to have the first coil cold before the second bar is wound round; but the third bar is wound on while the second coil is hot; the second and third layers, therefore, contract nearly simultaneously, and are kept in a state of tension by the first, which they compress to a certain degree, thus carrying out the theory of initial tension.



Fraser 9-inch Gun.

The barrel is made from a solid forged cylinder of cast-steel, drawn by heating and hammering; it is turned, bored, and chambered, then heated to a uniform temperature in a vertical furnace and plunged into a covered tank of rape-oil, where it cools and soaks. The muzzle-coil is constructed of two single coils, welded together endways. Each coil is formed by heating a long bar and wrapping it about a mandrel; this is next heated in a reverberatory furnace and welded under a steam-hammer Before being united, the two cylinders are turned and bored. The breech-coil is composed of a triple coil, a trunnion-ring, and a double coil welded together. The double coil is formed by placing a single coil, when cold, on a mandrel and winding over it, but in the reverse direction to break joints, a second bar; if over this a third bar is immediately wound in the same direction as the first, a triple coil will result. These coils are welded by being heated and hammered on end and on the sides. The trunnion-ring is made by welding slabs of iron together on the flat end of a bar, and gradually forming a ring by driving through the center wedges and mandrels increasing in size; the trunnions, one of which comes from the bar, are at the same time hammered into shape. The coils and the ring having been turned and bored, the latter is placed on a shoulder of the triple coil, the double coil is dropped through the trunnion-ring on to the triple coil, and the joints welded in this position. The cascabel is forged of good scrap-iron.

The different parts having been formed are accurately turned and bored with a slight taper. The B-tube, being heated, is dropped over the barrel, which is stood in a pit, a stream of cold water circulating through the bore. The half-formed gun is then placed on its muzzle, water forced through the bore, and the breech coil heated and slipped into position. The cascabel is screwed into the breech-coil abutting against the barrel, great care being taken that the contact is perfect. A tell-tale hole is cut along the thread on the cascabel to give warning by the escape of gas should the barrel break in firing. The vent is bored through hardened copper; it enters at near the center of the service-cartridge. This gives greater velocity, but also greater pressure. The large guns have from seven to ten grooves. The twist is uniformly increasing; the shape of the grooves is circular, with curved edges. Larger cannon are built up of a greater number of pieces. In some a coil (the belt) is placed between the muzzle and breech coils, with an additional coil (the waistcoat) under the breech-coil. Shoulders also are used, by which the parts when hot are hooked together. See *Armstrong Guns*, *Ordnance*, and *Woolwich Gun*.

FRAUD.—Any person in the military service of the United States who makes or causes to be made any claim against the United States, or any officer thereof, knowing such claim to be false or fraudulent; or who presents or causes to be presented to any person in the civil or military service thereof, for approval or payment, any claim against the United States, or any officer thereof, knowing such claim to be false or fraudulent; or who enters into any agreement or conspiracy to defraud the United States by obtaining, or aiding others to obtain, the allowance or payment of any false or fraudulent claim; or who, for the purpose of obtaining, or aiding others to obtain, the approval, allowance, or payment of any claim against the United States, or against any officer thereof, makes or uses, or procures or advises the making or use of, any writing, or other paper, knowing the same to contain any false or fraudulent statement; or who, for the purpose of obtaining, or aiding others to obtain, the approval, allowance, or payment of any claim against the United States or any officer thereof, makes, or procures or advises the making of, any oath to any fact or to any writing or other paper, knowing such oath to be false; or who, for the purpose of obtaining, or aiding others to obtain, the approval, allowance, or payment of any claim against the United States, or any officer thereof, forges or counterfeits, or procures or advises the forging or counterfeiting of, any signature upon any writing or other paper, or uses, or procures or advises the use of, any such signature, knowing the same to be forged or counterfeited; or who, having charge, possession, custody, or control of any money or other property of the United States, furnished or intended for the military service thereof, knowingly delivers, or causes to be delivered, to any person having authority to receive the same, any amount thereof less than that for which he receives a certificate or receipt, shall, on conviction thereof, be punished by fine or imprisonment, or by such other punishment as a Court-Martial may adjudge. And if any person, being guilty of any of the offenses aforesaid, while in the military service of the United States, receives his discharge, or is dismissed from the service, he shall continue to be liable to be arrested and held for trial and sentence by a Court-Martial, in the same manner and to the same extent as if he had not received such discharge nor been dismissed.

FRAYS.—All officers of what condition soever have power to part and quell all quarrels, frays, and disorders, though the persons concerned should belong to another regiment, troop, or company, and either to order officers in arrest, or non-commissioned officers or soldiers into confinement, until their proper superior officers shall be acquainted therewith; and whosoever shall refuse to obey such officer (though of an inferior rank, and of a different regiment, troop, or company), or shall draw his sword upon him, shall be punished at the discretion of a General Court-Martial.

FREEBOOTER.—A term commonly applied to one who wanders about for plunder; a robber; a pillager; a plunderer.

FREEDMEN'S BUREAU.—The branch of the War Department of the United States, established in 1865, to which was committed the supervision and management of abandoned lands, and the control of all subjects relating to refugees and freedmen from any district embraced within the territory covered by the operations of the army. It was managed by a Commissioner, with a number of Assistants. It was created to meet a special exigency: much of the work was long ago accomplished, and the principal functions of the Bureau ceased in 1870. During its existence the Bureau exercised a general supervision over the freedmen and other loyal refugees, protecting their rights, finding work and providing education for them, and furnishing medical treatment. More than 2100 day- and night-schools were in operation in 1869, with 2455 teachers and 114,552 pupils. The Bureau was instrumental in establishing institutions for the higher education of freedmen, such as Howard University at Washington, Atlanta University, Claflin University in South Carolina, and others. The number of rations issued to freedmen was over 15,000,000, and nearly 600,000 sick persons were cared for.

FREE-LANCES.—Roving companies of knights and men-at-arms, who, after the Crusades had ceased to give them employment, wandered from State to State, selling their services to any lord who was willing to purchase their aid in the perpetual feuds of the Middle Ages. They played their most prominent part in Italy, where they were known as Condottieri.

FREEMAN GUN.—A breech-loading rifle having a fixed chamber closed by a movable breech-block, rotating about a vertical axis at 90° to the axis of the barrel, and lying in the plane of the axis of the barrel. It is opened by cocking the piece and pulling back the horn of the breech-block; and is closed by pushing the horn forward with the right hand, a bevel on the left face of the breech-block pushing the cartridge home. When locked by the position of the breech-block it is also kept from turning by the front segment of the hammer engaging with a corresponding groove in the back of the block. It is fired by a center-lock of the usual pattern.

Extraction is accomplished by a bent lever pivoted below the chamber and struck by the ejector-cam, which, turning with the breech-block in opening the piece, rides over the curved horn of the extractor and draws back its upper end, carrying with it the cartridge-shell. Ejection is caused by a flat spring riding on a cam formed on the hub of the extractor, and thereby accelerating its action on the cartridge-shell when the latter has been started from its seat in the chamber in the act of opening the piece.

The arm has been modified so that the horn of the breech-block, instead of being solid with the block, is pivoted to it on a vertical axis, and has its lower portion cam-shaped, with a bearing on the side of the frame, so that a lever power is obtained in the first movement of opening the piece, when, if at all, the block is likely to stick. The hammer also has a projecting tooth on its forward surface, which engages with a notch in the under side of the firing-pin and retracts it when the hammer is cocked. The point of the firing-pin may thus be withdrawn from its impression in the cartridge-head, in order to allow the block to open freely.

FRENCH ARMY.—One of the chief Continental armies of Europe. Early in 1868 a Bill was carried through the French Chambers which raised the force of that country, nominally, to 800,000 men. The term of service was increased from seven to nine years. The rate of recruiting per annum was fixed at 100,000 men, selected by conscription; the proportion of which to the population (37,000,000) being about 1 to every 370. The nine years' service men were divided (as regards the 70,000 men who were called for service out of the 100,000) between five years passed under the Regimental Colors and four years in a General Reserve, called the Second Reserve. The remaining 30,000 men were enrolled in the First Reserve, and were not required to perform any military service in peace-time, except five months' drill in each of the five years. Those who were not drawn by conscription had to serve five years in the *Garde Mobile*, being called upon to take the field on emergency. Such was the military system of France when the war of 1870–71 broke out. It proved inefficient to produce a trained Second Reserve; and in order to insure the French army an ample and constant supply of recruits, the law of general military service of the First Republic was restored in its fullest vigor, in a Bill passed by the French Assembly in July, 1872. The present system alters entirely the military recruiting of that country, and is similar to the German one, as will be seen by the following principal clauses: Every Frenchman is liable to military service, and must serve personally, the system of substitute being abolished. He is called upon to serve from the age of 20 (instead of

21, as by the former law) to the age of 40, the period of service being thus distributed: five years in the Active Army; four years in the Reserve of the Active Army; five years in the Territorial Army; six years in the Reserves of the Territorial Army. Every man enrolled in each yearly contingent has to serve for twelve months at least, except those for the service of special arms—artillery, engineers, and cavalry, which require a longer training—and they have therefore to serve a much longer time. Notwithstanding all permanent exemption being abolished, there are certain strictly determined cases of a temporary kind which exempt men from the service, such as supporters of families, eldest brother of orphans, only son or grandson of widows, etc. Young men who have obtained university and college degrees, and those who belong to government schools, and who desire to continue their studies, may volunteer for one year. They are called *Volontaires d'un an*. The men of this class must defray at their own expense the cost of their uniform, equipment, and horse, if in the cavalry. After one year they have to pass an examination, and, if not successful, have to remain another year in the ranks. At the end of their term, they receive, as a rule, certificates of qualification as Non-commissioned Officers or Officers in the Territorial Army. Like all others, they are liable to be called upon to serve on the outbreak of war. The rate of recruiting by this new law is computed to give France a yearly contingent of 150,000 men, deductions being made on account of the "dispensed with" class. Each contingent is therefore, in different ways, subject to serve for twenty years, and consequently at the end of that period the forces of France will amount to an aggregate of twenty contingents of 130,000 each, with deductions for deaths and casualties, giving a total of 2,423,164 men. In addition to these levies, France has a Permanent Army of 81,722 men, belonging to the permanent effective, not recruited by means of the conscription, composed of Officers, Staff, Administrative Corps, *Gendarmerie*, etc. The active army in time of peace has (1875) a strength of 480,000 men, and in time of war, by calling in the trained contingents of 780,000 men, organized in corps, and ready to take the field at once on the outbreak of a war, has behind it "Troops of Reinforcement" amounting to 279,000 men, who have all served at least one year in the army. These Troops of Reinforcement will be distributed in the corps depots, together with the 150,000 men of the last class called up and not yet fully instructed. Thus the fighting army of 780,000 men may be increased by 429,000 men ready to fill up vacancies in the fighting corps.

The organization of these forces was the subject of the Bill passed by the Assembly, and promulgated in March, 1875; it is known as the *Loi des Cadres*. By this law, France is divided into 18 military regions, each garrisoned by an Army Corps, besides a special Corps (19th) for Algeria. Each Army Corps has 2 infantry divisions, 1 brigade of cavalry, 1 brigade of artillery, 1 battalion of engineers, and 1 squadron of field-train, besides staff and auxiliary services. The several Army Corps are recruited indifferently from the whole contingent, and during peace may be moved from region to region; but the Reserves are organized in their own regions. On the outbreak of war, the men of the Reserve will be mobilized near their homes, clothed and armed at depots already known to them, within a day's walk, and sent to swell the ranks of that Corps which happens to be stationed in the region at the time. The Territorial Army will, at all times, belong to its own region. Its duties in war will be to garrison fortresses, defend strategic points, work the lines of communication, and set the active army free for field-operations, but, when urgent, will also co-operate in the field with it. The French army is composed as follows: 144 regiments of the line, each regiment consisting of 4 battalions, and each battalion of 4 companies, with 2 depot companies; 30 battalions of foot-chasseurs (*chasseurs à pied*), each battalion of 4 fighting companies and 1 depot company. In addition, the 19th *Corps d'armée*, quartered in Algeria, comprises four regiments of *zouaves*, each regiment of 4 battalions, consisting of 4 fighting companies and 1 depot company; three regiments of Algerian sharp-shooters (*turcos*), organized like the *zouaves;* one foreign regiment of 4 battalions, each 4 companies strong; five discipline companies (*zéphyrs*). Each fighting company consists of 1 Captain, 1 Lieutenant and 1 Sub-lieutenant, 1 Sergeant Major, 4 Sergeants, 1 Quartermaster Sergeant, 8 Corporals, 2 drummers or buglers, and 66 privates; total per company on peace-footing, 3 officers and 85 rank and file. At 16 companies per regiment, this gives an aggregate of 48 officers and 1312 rank and file. The two depot companies present an effective of 6 Officers, 32 Non-commissioned Officers, and the number of men remains unknown. On the war-footing, each company is increased by 1 Lieutenant or Sub-lieutenant, 1 Quartermaster Corporal, 4 Sergeants, 8 Corporals, and 2 drummers. The cavalry branch of the service consists of 77 regiments, viz.: 12 regiments of cuirassiers, 26 regiments of dragoons, 20 of *chasseurs*, 12 of hussars, 4 of *chasseurs d'Afrique*, and 3 regiments of *spahis* (native cavalry of Algeria). The 70 home regiments form 18 brigades of 2 regiments each, one of which is attached to each *Corps d'armée*. This leaves 34 regiments available to form independent cavalry brigades and divisions. Each of the 70 home regiments consists of 5 squadrons, having on peace-footing 45 officers, 830 men, and 740 horses. The African regiments are 6 squadrons strong, and their effective amounts to 59 officers, 978 men, and 930 horses. In addition there will be 19 squadrons of cavalry volunteers, who will supply the Generals and Staff Officers with men capable, from previous instruction, of performing, efficiently, duties as guides, escort, orderlies, etc. The artillery consists of 38 regiments quartered in France, forming 19 brigades, 2 per Army Corps. The first regiment of each brigade consists of 3 batteries *à pied* (without guns), 8 batteries *montées* (with guns), 2 *montées* depot batteries (provided with guns for drill and practice purposes); in all 65 Officers, 1349 Non-commissioned Officers and men, and 635 horses. The second regiment of each brigade consists of 8 mounted batteries, 3 batteries of horse-artillery, and 2 mounted depot batteries; 68 officers, 1369 men, and 878 horses. There are 2 regiments exclusively intrusted with the Bridge and Ponton Department, 10 companies of Artillery Artisans, 3 Rocket Companies, and 57 companies of the Artillery Train. The Engineering Department consists of 4 regiments of sappers and miners, and that of the Military Train of 20 squadrons.

Besides the above forces, there are certain auxiliaries, viz.: Military Clerks and Artisans; Ambulance Staff and Attendants (*infirmiers militaires*); Military Chaplains; the *Gendarmerie* and a regiment of Firemen of the City of Paris, who are picked men from the army; a Corps of Military Interpreters, a Telegraphic Staff and Corps, a Railway Staff and Corps, the three latter being borrowed from the German system. The various railway lines in the rear of the army are to be worked by these Corps, under military superintendence in front of the lines. To secure a competent military Railway Staff, a certain number of sappers and miners, after one year's service with the Colors, will be told off to the various railways to complete their professional instruction.

The French army is officered partly from the ranks, partly from the Military Colleges, specially from the latter. Major Brackenbury, in the preface to his translation of the law on the general organization of the French army, adverts to the subject of the principles on which it has been remodeled, as follows: 1st. General obligation to military service. 2d. A peace organization approaching as nearly as possible the organization for war. The Corps are always ready with their Staffs and administrative services, and only require the addition of their Reserves—always close at hand—in order to go into the field. Their stores are also on the spot. 3d. Decentralization. Each General mobilizes his own Corps, is responsible for his own first supplies, and can have no one but himself to blame if he is slow or wants anything. 4th. On the other hand, the Government has a Corps of Inspectors, who will during peace detect the incompetence of a Commander. 5th. The Control is carefully separated from the Administration, and the Generals are expected to be good administrators as well as good leaders of troops. 6th. Recruiting, remounts, hospitals, etc., are managed by the Territorial Staff in each region, but always under the General Commanding the Corps then present. When a Corps is mobilized and quits its region, the command of the region and its territorial troops is handed over to an officer previously appointed by the Minister. In order to act up to the spirit of the new law, the War Office has been reconstituted under conditions more in accordance with the organization of the army; and the Department of the Chief of the General Ministerial Staff comprises now a Ministerial Cabinet and five Bureaux, namely: First Bureau—general organization and mobilization of the army; positions and strength; general correspondence; Second Bureau—military statistics; historical office; Third Bureau—military operations; instruction of the army; topographical office; Fourth Bureau—*Etappen* and railway service; execution of movements of troops; transport of troops by land and sea; Fifth Bureau (or war depot)—technical services; collections; material and accounts of the General Staff. Two Deputy Chiefs of the Staff are attached to the Chief of the Staff.

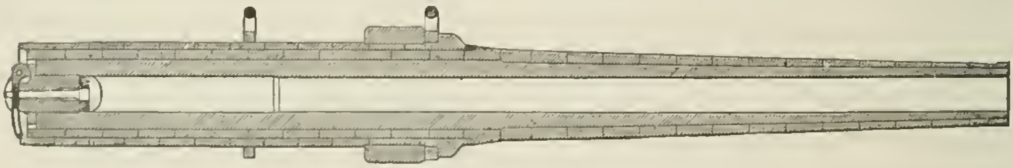
FRENCH ARMY ORDNANCE.—The broad features of construction of the army heavy ordnance are essentially those finding place in the naval guns, but the power deemed necessary for land purposes is much more limited, of course, than for marine and sea-coast uses; and hence we find that a 24^{cm} gun is the highest type introduced into this branch of the service. The steel guns are known as the Modèle de Bange. The body of the gun is composed of a tube of cast-vice of France. There are no novelties to point out in this construction other than those stated. The charges are 84 lbs. of powder and 336 lbs. weight of projectile for the 24^{cm} steel; and 62 lbs. and 265 lbs. for the 24^{cm} cast-iron and steel constructions. The former gives (it is reported from official sources) a velocity of 1598 feet, and a resulting muzzle-energy of 6000 foot-tons.

The Modèle de Bange, 24^{cm}, it will be seen on an inspection of the accompanying drawing, is a well-proportioned gun of extreme simplicity in design; the only part of any moment in a constructive point of view being the body. The weight of the entire gun is only 13.75 tons. The frettes, trunnion-bands, and other parts outside of the core weigh 7 tons. All these parts are small in size, hence readily handled, the rough-turned steel forgings from steel-works are readily obtained, the only prominent part being the body. The assembling and finishing of the gun is simple work, and within the capacity of ordinary machinery and appliances. The only question is if it has sufficient longitudinal (breech) strength. However this may be, it is a construction well worthy of consideration.

The following table gives the charges, etc., of the more important guns of the French service, and also shows their relative energies per ton of metal:

Caliber	Charge	Projectile.	Initial velocity.	Muzzle-energy.	Energy per ton of metal.	Kind.
	Lbs.	*Lbs.*	*Feet.*	*Ft-tons*		
42^{cm}....	617.3	1,726	1,738	36,628	485.8	Navy.
37^{cm}....	545.6	1,177	1,955	31,180	415.7	Navy.
34^{cm}....	462	924	1,955	24,482	415	Navy.
27^{cm}....	237.6	464	1,955	12,294	396.6	Navy.
31^{cm}....	440	935	1,950	24,647	493	Schultz.
24^{cm}....	84	336	1,600	6,033	430	Army steel.

It will be seen that the views of the French engineers on construction are about the same as those now existing amongst English constructors, and that

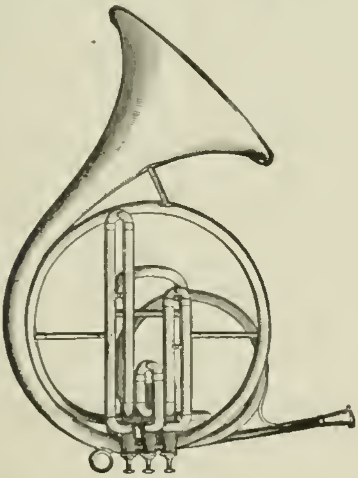


Modèle de Bange, 24^{cm}.

steel (tempered in oil and annealed), reinforced by frettes of puddled steel (tempered in oil or water). The breech-frette is prolonged in rear of the base of the tube, forming a protection for the breech-mechanism. The trunnions, except in field-guns, are hollow. Pieces of a heavy caliber have carrying-handles. The frette first placed in position abuts against a shoulder on the tube, which prevents any forward sliding. (In the 180^{mm} and 240^{mm} guns, fretted all the way to the muzzle, it is the last cylindrical frette.) The extremity of the chase is strengthened by a swell of the muzzle shaped like a band. The seat of the breech-mechanism has nearly the same diameter as the bore. The threads of small dimensions have a very short pitch. Their section is a rectangular isosceles triangle, the top of which is flattened. The cylindrical powder-chamber, with a diameter nearly the same as that of the bore, is connected with the latter by a truncated surface of short length where the grooves commence and against which the projectile abuts when seated home. The ordinary screw fermeture, but with the De Bange gas-check, is used. The 24^{cm} gun, model 1876, is a cast-iron gun similar in construction to the model of 1870 for the body of the gun, the fermeture differing, however, in the substituting of the De Bange gas-check, which is universally used in the land-ser-they are striving to reach results in power combined with lightness which are gradually rendering *imperative* the ultimate discarding *in toto* of cast-iron in their models. A brief summary may here be added in closing this notice of French heavy ordnance. 1. A long and patient test of, and an experience (in breech-loading systems) with, steel-fretted cast-iron has resulted in failure and abandonment. 2. The adoption of the model of 1870, cast-iron hooped and tubed, has given good results, warranting the introduction of this type in service. 3. That with the development of the steel interests of France, the French Authorities are not satisfied with cast-iron entering into their constructions, and are resorting to steel entirely, and that they contemplate the disuse of the former. 4. That wire guns are being persistently experimented with, and are looked to as promising to be introduced as the guns of the future. 5. That constructions looking to the "division of strains" are regarded as the probable solutions of the dangers arising from the combination at the breech of the longitudinal (breech) and tangential (breech) stresses; and that the Schultz plan is preferred. 6. That a new, simple, and an apparently effective fermeture, other than the Broadwell, has been tested with success, approved and adopted at least in the land service of France. This fermeture is known as the De Bange. 7. The undoubted tendency in France, in England, and in other countries is to resort to steel constructions for ordnance. This leaves us to remark that the use of this metal in some form or other—as developments in production in our country may decide—is a foregone conclusion; and that some plan looking to its speedy, *practical* introduction in our fabrications cannot too soon be inaugurated. See *Ordnance.*

FRENCH FRICTION-TUBE.—The French primer, of which ours is a modified and improved form, was adopted in the French army in 1847. The large tube with a cross-head at the top to prevent its entering the vent too far, is stopped at the top by a wooden plug held in place by an indented girdle. Below this and inside the large tube is a smaller tube, the upper part of which is filled with a fulminating powder composed of $\frac{1}{3}$ chlorate of potassa and $\frac{2}{3}$ sulphuret of antimony mixed with gummed water or alcohol. This is pierced through the axis to give passage to the friction-wire, the lower end of which is flattened and serrated. This serrated part remains in the empty part of the small tube, the lower end being clinched around the end of the tube. The small tube being prepared with the fulminate, the wire is introduced into the large tube, passing out through the hole in the axis of the wooden plug. The wire is then twisted on itself and bent down along the tube. The primer is then finished by filling the lower ends of both tubes with musket-powder, and closing the end of the large tube with a mixture of wax and pitch. The opening around the wire where it passes through the wooden plug is closed with a drop of wax.

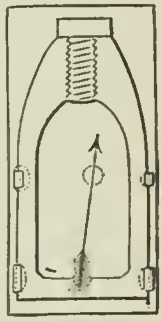
FRENCH HORN.—A wind-instrument, commonly called in the United States *horn;* in Italy, *corno;* in France, *cor de chasse.* Its form is that of a lengthy tube of brass, with a large bell-shaped ending. For greater convenience the tube is coiled up into continuous circles, lying side by side, the coils being soldered together, to keep them in their position.



French Horn.

It is sounded by means of a mouth-piece, in form like a little hollow cup. The thinner the sheet-brass is of which the horn is made, the more easily can the sound be produced. The sounds obtained on the French horn are the harmonics of the sound of its whole length, a fundamental sound which cannot be produced by the mouth. As those sounds form only a limited scale, the notes wanting are artificially made, by the hand being inserted into the bell, so as to flatten a higher note down to a lower one. These flattened notes are called stuffed notes, as the sound of them is muffled. The French horn in its natural state can only be played in one key; but by means of crooks, which are added to increase the length of the tube, it can be transposed into any key. When at its greatest length it measures, from the mouth-piece to the end of the bell, 16 feet. The music for the French horn is always written in the key of C, with the key of the composition marked at the beginning of each movement; thus, corno in D, etc., guides the performer as to the crooks he must use in order to play the notes in the key indicated. The stuffed notes on the French horn being very defective in quality of sound, in comparison with the great beauty of the open notes, many inventions have been from time to time tried to remedy them, the most successful of which is the valve-horn, which is constructed so that the performer can, by means of three valves, lengthen or shorten the tube so as to produce any note in the chromatic scale, as a harmonic of the length of the tube, and consequently all the notes are of the same quality of sound, and open notes. The valve-horn is now generally used as a solo instrument with greater effect than the common French horn. As a band and orchestral instrument the French horn is of great importance. There are never less than two French horns in an instrumental score, and in many great works four are absolutely necessary. The date of its invention is lost in antiquity. See *Band.*

FRENCH PROJECTILE.—The projectile used in the French field-service is made of cast-iron, and has twelve zinc studs on its sides, arranged in pairs, so as to fit the six grooves of the gun. For the larger cannon-projectiles but three studs are used, and these are cast on the projectile, nearly opposite to its center of gravity; the bearing sides of the studs are faced with white metal to diminish friction against the grooves of the bore. The shape of the grooves is such as to center the projectile. The latter projectile is used with increasing, the former with grooves of uniform, twist. Russian, Austrian, and Spanish artillery-projectiles belong to this studded or button class, but differ from each other in the details of their construction. See *Compression-projectiles* and *Projectiles.*



FRENCH SIGHTS.—In this system, employed when the target is invisible, specially constructed sights (used in the ordinary sight-slots) are provided, having cross-bars on their heads, divided into scales of equal parts, and parallel to the axis of the trunnions.

The whole of the rear bar can slide laterally through the head of the rear sight, and there is a scale of degrees and minutes on the cross-bar which registers the amount of sliding or "deflection." The other bar is a fixture. Each bar carries a sliding sight-leaf.

If the target can be seen at any time from the battery, the piece is laid in the ordinary way, both sliders being clamped at the same graduation near the middle of each bar. A plumb-line and a vertical chalk-line drawn on a board (or, in confined positions, two plummets hanging from frames in the rear) are aligned on the sights, should firing through smoke or by night be afterwards expected. These sights are chiefly employed with the siege-artillery. See *Sight.*

FRET.—A figure, used in Heraldry, resembling two sticks laid saltierwise, and interlaced with a mascle. When six, eight, or more pieces are represented crossing and interlacing like lattice-work, the shield is said to be *fretty.* See *Heraldry.*

FRETTAGE.—The introduction and development of hooping cast-iron with steel bands in strengthening the former material in gun-construction have been noted with much interest. It appears that the first attempt was made in 1836, at the foundries of Liege, in Belgium, where the minor powers of Europe, and even Russia, procured their cannon at that time; resort being had, however, also to the well-known Swedish foundries of Fingspong and Aker. The method was first brought into notice at Ruelle, in 1843. It was introduced a few years later by Blakely in England; and in 1859 it was tested again in France, at Vincennes, by the Navy Department, and officially adopted for all its rifled guns. In 1864, in the model then adopted, the exact allowances for shrinkage were established, based upon both practical and theoretical observations. The allowance for shrinkage, it is intended, shall be such as to secure a compression of the interior strata according to the theories of Gadolin and Lamés. The amount of diminution of diameter of tubes varies from .003 to .007 inch. It is hardly necessary to allude to the fact that the large constructions for naval service have two series of puddled steel frettes, made at Le Creusot and Rive de Gier. The banded portion of the cast-iron body is, according to general rules, about one caliber in thickness, and the bands .25 caliber for each row, giving a thickness at the seat of dangerous pressures of about one and one half calibers. The operation of shrinking on the hoops requires but simple and ordinary appliances. An oven, modeled after the ones employed in England for heating tires for wheels, supplies the means for heating up the frettes to the proper temperatures. They are transferred from thence by means of a small crane, and are placed in their proper positions on the exterior of the prepared cannon-body by two or three workmen. A circular tube and collar containing water, which escapes in jets on to the superimposed frette, supplies the means for cooling. It is applied not directly after the placing of the frette in position, but in about ten minutes after the latter operation has been completed. After preparing the body, and the assemblage of the first row of bands, the gun is transferred to the boring-lathe, and the exterior of the frettes accurately turned, and the preparations for the application of the second row of bands completed. After this row has been superimposed the gun is sent to the machine-shop for the final process of fitting the fermeture, rifling, and other necessary work to complete the manufacture. Proof-frettes are tested for elasticity, and proof of endurance by a shrinkage test. A cast-iron cylinder is used over which the experimental hoops are placed under a definite tension by heat, and when the parts are cut the cylinders are broken up and the frettes under proof measured and otherwise examined. A shrinkage determined upon, say, nearly up to .002 of the diameter, and a slightly less one for trunnion-bands, should attain without any permanent set resulting in enlargement. They should withstand an enlargement not exceeding .004 without rupture, or development of serious superficial defects sufficient to warrant rejection. Based upon these trials, the frettes are prepared which are to be used in construction. In the application of frettes or trunnion-bands to the bodies of guns the establishment of the limits of shrinkage must largely depend upon the results of the testing-machine for physical properties, and limits which may be determined by one set of experiments may be non-concurred in by another, operating on different metals used in different countries. The data resulting from French experiments are, therefore, matters of interest, but furnish no definite standard for following absolutely when other steels are used. See *Tubage*.

FREYTAG SYSTEM OF FORTIFICATION.—In this system the maximum of the angles of bastions is fixed at 90°. The flanks are perpendicular to the curtain, and the whole enceinte is surrounded by a fausse-braye on a level with the ground. The salients of bastions are covered by lunettes, and the curtains by ravelins. The escarps have no revetment. The chief defense of this fortification rests on the wet ditches; which, however, fail in frosty weather. The ravelins are too small to cover even the curtain, and the lunettes, when taken, afford a very advantageous lodgment for the enemy.

FRICTION.—When one body rubs against another as it moves, a certain force is felt to resist the motion. This resistance is called *friction*. As a considerable proportion of the motive power in all operations is spent in overcoming the friction of the parts of the machine upon one another, and is thus lost for the useful work, it is of great importance to understand the nature of this obstructive force, with a view to reduce it to the least possible amount. Accordingly, a great many careful experiments have been made on this subject, and the result is a number of precise and valuable facts or laws regarding friction which are now considered certain and reliable. The more important may be thus stated and illustrated. When a block of oak—say a cubic foot, which weighs about 60 lbs.—is placed on a horizontal table of cast-iron, the two surfaces being flat and smooth, it requires a force of nearly $\frac{2}{5}$ the weight of the block, or 24 lbs., pulling horizontally, to make it slide along the table. This measures the friction between the two surfaces. Another block of the same size and shape laid on the same table would require the same force to draw it; and if the two were laid side by side, and fastened together so as to become one block, it would evidently require double the force, or 48 lbs., to draw the double block; the amount of the friction being thus still $\frac{2}{5}$ of the weight, or of the pressure between the two surfaces. But suppose that, instead of being laid side by side, the second block were laid on the top of the first, what is to be expected? Here the weight is doubled as before, but the extent of rubbing surface remains unaltered; it would be natural, therefore, to expect that this would make a difference, and that, though the friction would, of course, be increased, the increase would be less than in the former case. Experiment, however, shows that there is no difference, and that the friction is exactly double in both cases. In short, the unexpected and important fact is established that, *within certain limits, the friction of any two surfaces increases in proportion to the force with which they are pressed together, and is wholly independent of the extent of the surfaces in contact.* The amount of friction between two bodies is thus a constant fraction or proportion of the force with which they are pressed against each other. This fraction differs for the different kinds of surfaces. Thus, between oak and cast-iron it is, as already stated, about $\frac{2}{5}$, or more exactly, .38; for wrought-iron on wrought-iron (we speak at present of dry surfaces, without grease or unguent of any kind) it is .44; for brass upon cast iron, .22. This constant fraction (expressing the proportion between the pressure of two surfaces and their friction) is called the *coefficient of friction* for these two surfaces. Friction is very much diminished by the use of grease or unguents. The coefficient of wrought-iron upon oak, which, in the dry state, is .49, is reduced by the application of water to .26, and by dry soap to .21. The result of experiments on this subject is stated to be "that with the unguents hog's lard and olive-oil interposed in a continuous stratum between them, surfaces of wood on metal, wood on wood, metal on wood, and metal on metal (when in motion), have all of them very nearly the same coefficient of friction, the value of that coefficient being in all cases included between .07 and .08." Tallow gives the same coefficient as the other unguents, except in the case of metals upon metals, in which the coefficient rises to .10. In the case of wood on wood, black-lead is frequently employed for the same purpose. The most important fact, perhaps, and one that could hardly have been anticipated before experiment, is *that the friction of motion is wholly independent of the velocity of the motion.* The resistance to the motion of a wheeled carriage proceeds from two sources—the friction of the axle, and the inequalities of the road. The resistance of friction to the turning of a shaft in its bearings, or of an axle in its box, has evidently the greater leverage the thicker the journal or the axle is; the axles of wheels are accordingly made as small as is consistent with the required strength. The resistance that occurs between the circumference of the wheel and the road constitutes what is called *rolling* friction. There are on all roads, to a greater or less extent, visible rigid prominences, such as small stones, in passing over which the wheel and the load resting on it have to be lifted up against gravity. But even if these were wanting, the hardest road yields, and allows the wheel to sink to a certain depth below its surface; so that in front of the wheel there is always an eminence or obstacle, which it is at every instant surmounting and crushing down. This is the case even on iron rails, though of course to a much less extent than on any other road. Now, for overcoming this resistance, it can be shown, on the principle of the lever, that a large wheel has the advantage over a small one; and by numerous experiments the fact has been fully established that over horizontal roads of a uniform quality and material *the traction varies directly as the load, and inversely as the radius of the wheel.* The best direction of traction in a two-wheeled carriage is not parallel to the road, but at a slight inclination upward, in proportion to the depth to which the wheel sinks in the road. On a perfectly good and level macadamized road the traction of a cart is found to be $\frac{1}{30}$ of the load; that is, to draw a ton, the horse requires to pull with a force equal to 75 lbs. On a railway the traction is reduced to $\frac{1}{280}$ of the load, or to 8 lbs. per ton. While friction thus acts as an obstruction to motion, and wastes a portion of the motive power, it has also important uses. It is, in fact, an indispensable condition, no less than gravity, in the stability of every structure, and in every mechanical motion on the earth's surface. How essential it is to our own movements we experience when we try to walk on ice! Even on ice there is still considerable friction, so that one foot can be slightly advanced before the other; were it altogether annihilated, we could not stir a fraction of an inch, even supposing we could stand upright. Without friction, a ladder could not be planted against a wall, unless there were a hole in the ground to retain the foot. In short, no oblique pressure of any kind could be sustained. The advantage of railways consists chiefly in the diminution of friction; but were this diminution carried much further, there could be no motion whatever, at least by means of locomotives. Without a considerable friction, the driving-wheels of the locomotives would slide round on the rails without advancing; and this sometimes happens when particular states of the weather render the rails as if they were greased. The force of friction is often directly employed in mechanics. It is used, for instance, to communicate motion by means of belts, chains, etc. It is the force that holds a knot. It is specially useful when a machine, with great momentum, has to be checked or arrested in its motion. The best example of this is the *brake* used on railways. By means of a system of levers, blocks of wood are made to press upon the circumferences of a number of the carriage-wheels; and thus the momentum of a train weighing hundreds of tons, and moving with a velocity of perhaps 50 miles an hour, is gradually destroyed in a wonderfully short space of time. *Friction-wheels* are employed to diminish the friction of axles on their supports. Two wheels, of a large circumference in proportion to their weight, are located close together, parallel to each other, and so that the one seems to overlap the half of the other; in the notch thus formed by the upper circumferences of the wheels one end of the axle rests; a similar arrangement being made for the other end. The friction, which formerly acted directly on the axle, is by this arrangement referred to the axles of the friction-wheels, and is, by the laws of mechanics, reduced in the ratio of the circumference of the friction-wheel to the circumference of its axle. In order to render the friction of the friction-wheels themselves the least possible, they are made as light and as large as is practicable.

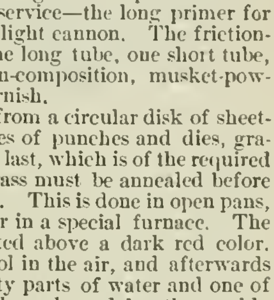
FRICTION-CHOCKS.—Brakes attached to the common standing garrison-carriages of guns, so as to raise the trucks or wheels off the platform when the gun begins to recoil, to prevent its running back.

FRICTION CONES.—A kind of coupling in which motion is communicated by the friction of the surface of a cone fixed on one shaft against the inner surface of a similar cone, into which it may be thrust, fixed on another shaft. The friction-cone prevents the elevating gear from breaking on firing, by enabling the gun to twist the cone round inside the *worm-wheel,* when it gives a severe blow.

FRICTION-PLATE.—A plate of iron placed on the side of the trail-beam of wooden gun-carriages at that point where the wheel locks with the carriage. The plate is placed in that position to prevent injury to the trail when the limber is being turned at an angle to the gun-carriage. Friction-plates are also used to check the recoil of guns. See *Elswick Compressor* and *Recoil.*

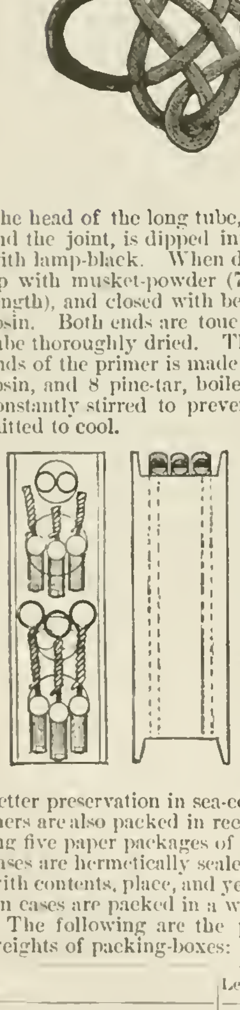
FRICTION-PRIMERS.—The friction-primer for cannon is a small tube of brass filled with gunpowder, which is ignited by drawing a flat wire with serrated edges briskly through friction-composition contained in a smaller tube inserted into the first near the top and soldered at right angles to it. A lanyard, with a hook attached, is used to ignite the primer. Two kinds are in use in the service—the long primer for heavy, and the short for light cannon. The friction-primer is composed of one long tube, one short tube, one wire igniter, friction-composition, musket-powder, wax, and shellac varnish.

The *long tube* is made from a circular disk of sheet-brass by means of a series of punches and dies, gradually diminishing to the last, which is of the required size of the tube. The brass must be annealed before each drawing or reducing. This is done in open pans, or in a revolving cylinder in a special furnace. The brass should not be heated above a dark red color. It is then allowed to cool in the air, and afterwards pickled in a bath of forty parts of water and one of sulphuric acid to remove the scale, and then thoroughly washed to remove all trace of acid. Thickness of sheet-brass disk, .036 inch; diameter, .62 inch for short, and .98 inch for long primers. The tube is cut to the prescribed length, measuring from the closed end, by means of a circular saw, and the holes for the short tube and wire igniter are drilled and the burs removed. Length of long tube for short primer, 1.75 inch; for long primer, 2.35 inches; exterior diameter, maximum, .195 inch; minimum, .187 inch; interior diameter for short primer, .175 inch; and for long primer, .155 inch; diameter of holes, .15 inch and .06 inch.



The *short tube* is derived from the longer one by using two additional punches and dies, reducing the size each time. It is made to the proper length by circular saws placed at the required distance apart, and the bur is removed by rolling in a barrel. Length of the shorter tube, .44 inch; exterior diameter, .15 inch; interior diameter, .133 inch. One end of the short tube is dipped in a solution of zinc chloride, inserted in the hole drilled in the long tube, heated in the flame of a spirit-lamp, until solder melts, and soldered with soft solder; it is then washed and dried. The *wire igniter* is made of brass wire .05 inch diameter, annealed, cut to the proper length, and pressed flat at one end by a machine for that purpose. The flat end is serrated by a punch and die with dentated edges, and the tip is annealed in the flame of a spirit-lamp. Length of wire, 3.4 inches; length of flattened end, .65 inch. The *friction-composition* is made of 55 parts antimony trisulphide, 37 parts potassium chlorate, 5 parts flowers of sulphur, and 3 parts gum arabic. The materials must be finely pulverized, and mixed thoroughly in a bowl of stone-ware by stirring with equal quantities of alcohol and water until the mixture attains the consistency of paste.

The small tube is charged by pressing the open end in the friction-composition spread on a flat piece of zinc, and brought to the consistency of soft putty, the long tube being closed its whole length with a wooden or metal plug. A conical hole is made in the composition while yet moist, with a conical drift, and the surplus composition removed; the wire igniter is passed through the short tube and through the small hole in the long tube, the round end first, leaving the annealed tip projecting out of the open end, which is then closed by pressing the top and bottom together firmly with pincers, and bending the tip against the bottom. The end of the wire igniter is doubled on itself and twisted, leaving a loop .2 inch diameter. The head of the long tube, including the short tube and the joint, is dipped into shellac varnish colored with lamp-black. When dry, the long tube is filled up with musket-powder (7 or 10 grains according to length), and closed with beeswax mixed with tar and rosin. Both ends are touched with varnish, and the tube thoroughly dried. The material for closing the ends of the primer is made of 15 parts of beeswax, 5 rosin, and 8 pine-tar, boiled 2½ hours on a slow fire, constantly stirred to prevent burning, and then permitted to cool.



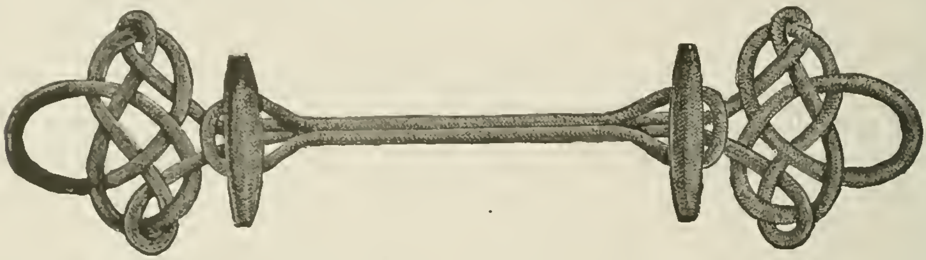
To pack the primers, rectangular wooden blocks are made, having holes .38 inch and .57 inch in diameter, bored in two opposite ends. The primers are placed in the holes, 5 or 10 to each block. The block is covered with a paper wrapper, which is then varnished. A printed label tells contents, place, and year of manufacture. The blocks are packed in wooden boxes containing 1000 of five primers each, or 100 of ten each. For better preservation in sea-coast fortifications, the primers are also packed in rectangular tin cases, containing five paper packages of 20 primers each. The tin cases are hermetically sealed, japanned, and stenciled with contents, place, and year of manufacture. Fifty tin cases are packed in a wooden box.

The following are the principal dimensions and weights of packing-boxes:

	Length	Width.	Depth.	Weight
	Inches.	*Inches.*	*Inches.*	*Pounds*
Cases for short primers....	7.35	2.2	2.1	1
Cases for long primers. ...	7.6	2.65	2.2	1.56
Box for 1000 blocks	22	12	12 5	83
Box for 100 blocks { Long primers.	16	9	6.125	26
Box for 100 blocks { Short primers.	12	9	6 125	22
Box for 50 tin cases, short primers	22	11.5	7 5	70
Box for 50 tin cases, long primers.	27.5	11.25	7 75	90

The following materials are required for 10,000 friction-primers: 136 pounds sheet-brass, .036 inch thick, 6.75 inches wide, for long primers; 60 pounds sheet-brass, .036 inch thick, 6.75 inches wide, for short primers; about ⅙ returned as scrap; 20 pounds brass wire, .05 inch; 1.25 pound solder; 1.5 pound antimony trisulphide; 1 pound potassium chlorate; .125 pound flowers of sulphur; .094 pound gum arabic; 7.5 pounds beeswax; 2.5 pounds rosin; 11 pounds musket-powder; 2 quarts pine-tar; 1.25 quart varnish (.75 pound shellac, 1 quart alcohol, .25 ounce lamp-black); .5 pint alcohol for friction-composition. See *Electric Primer, Fire-works, French Friction-tube, Maynard Primer,* and *Percussion Primer.*

FRILL.—An ornamental appendage to the shirt which officers and soldiers generally wore with regimentals. A small aperture was usually made at the top to admit the hook and eye of the uniform-coat. Enlisted men generally wore frills detached from the coat.



Frog of Officer's Overcoat, U. S. Army.

FRISRUTTER.—An instrument made of iron and used for the purpose of blocking up a haven or river. The beams through which the upright bars pass are usually 12 feet in length, and the upright bars that go through the beam are of such length that when the frisrutter is let down into the river, they will at high water reach within 5 feet of the surface.

FROCK.—In the British service, the undress regimental coat of the Guards, Artillery, and Royal Marines.

FROG.—1. A button or toggle of spindle shape and covered with silk or other material, which is passed through a loop on the opposite side of the breast of a military cloak or overcoat, serving to fasten the two breasts together. The drawing represents the frog or agraffe for officer's overcoat as at present worn in the United States army.—2. The loop of a bayonet- or sword-scabbard.—3. A horny wedge-shaped substance within the cavity of a horse's hoof. The function of the frog is to share in the pressure on the foot, and by its elasticity to relieve or distribute the pressure on the hoof.

FROGGED.—A term used in regard to uniforms, and applied to stripes or workings of braid or lace, as ornaments, mostly on the breast, on the plain cloth of which a coat is made.

FRONDE.—A sling used in France by the Huguenots at Sancerre, as late as the year 1572, in order to save their powder. There were two kinds, the one which was used in throwing a stone from the arm, and the other fixed to a lever and so contrived that a large quantity of stones might be thrown into the enemy's camp. The *fronde* or sling was used by the Romans on three different occasions, viz.: when they sent their light-armed men, called *Velites*, forward to skirmish before a general engagement; when they wished to drive the enemy from under the walls of a town which they were preparing to storm; and finally to harass and wound the men in the enemy's works. This weapon, together with the bow and arrow, may be numbered among the primitive arms of mankind.

FRONT.—1. A word of command signifying that the men are to face to their front; also to cast their eyes to the front after dressing.—2. The opposite to rear. The front, with reference to an alignment, is the direction of the supposed enemy. Used as a general term, the word signifies the direction in which soldiers face when occupying the same relative positions as when last told off. The front in artillery is the direction to which the horses' heads turn when the battery is limbered up.

FRONTAGE.—This term is expressive of the ground troops in line occupy either on parade or in camp. Cavalry in one line requires one yard to each file, and 12 yards between squadrons. Artillery in line, whether a field or horse-artillery battery, occupies 95 yards, and 19 yards between battery and battery, or between other troops. The frontage required by infantry is 2 feet per file, with intervals of 30 paces between battalions. In camp, the frontage, as a general rule, of cavalry and infantry should correspond with the space covered by the regiments when deployed into line (allowance being made for intervals between corps), and the lines of tents should be on the prolongation of the squadrons or companies as they stand when in column. When troops are encamped in two or three lines, from 200 to 500 yards should be left clear between the rear of one line and the front of that behind. The frontage of a battalion of infantry in camp on war establishment occupies 320 yards, a regiment of cavalry 256 yards, and a battery of artillery 110 yards.

FRONTAL.—The metal face-guard of the soldier. The term is frequently applied to anything worn on the face or forehead.

FRONTIER DEFENSE.—Military engineers, and other writers on this branch of the military art, have proposed systems of defensive lines for retarding an assailant at the frontier, of a more or less complicated character; the point aimed at in all cases being to make the works of each line of sufficient strength to defy an open assault even when their garrisons are reduced to their least number, and to combine this obstacle with the active effort of an army holding the open field, and maneuvering in connection with the fortified points, to threaten the flanks and rear of an invading force that might attempt to force its way through the defensive lines without carrying some of the works by a siege. Although hypothetical cases of this character do very well to hang an argument upon, they are of little practical use, as the points that must necessarily be fortified will be those which lie upon the main avenues of access to the interior from the frontier; as upon these also must lie the principal centers of population from the frontier to the interior. The problem in each case will be therefore a special one, and must be treated upon its own data. In the organization of the inland frontier fortifications of a State, the points to be principally regarded are the principal avenues of access to it, and their topographical features as they lend themselves more or less to strengthen the artificial defenses. In conducting an invasion across an inland frontier, the march of the enemy must necessarily be along the roads that intersect it, as these afford the only means for transporting the *matériel*, etc., of the army. The points, therefore, or places in their neighborhood where the principal roads or other avenues of communication cross the frontier, particularly those which lead to the great centers of population and wealth, are the ones which would necessarily call for permanent defenses. No absolute rule can be laid down for the distribution and strength of such works along a frontier. Everything must depend upon the more or less of facility presented to an enemy for penetrating at one point rather than another, and of the ulterior advantages the one may present to him over another. Rivers and mountain-ranges are the natural fortifications of States; and where they form the frontiers they greatly facilitate the application of artificial defensive means, as they present but few, and those in general, important points of access. When these points on a river are fortified, an invading force, however powerful, cannot without great risk cross the river without first gaining possession of them; for, even should a sufficient detachment be left to observe and blockade the fortresses, the main army, in case of retreat or any disaster, might be placed in an extremely critical position, in its movements to recross the river, with the garrisons of the fortresses threatening its flanks and rear. In offensive operations fortresses upon a river frontier form one of the strongest bases of operations. If a river intersects the frontier, the point where it crosses it, or some one in its vicinity, should be occupied by a permanent work; among such points those are more peculiarly necessary to be held where a river forming the frontier is intersected by another navigable one which lies wholly within the frontier. The importance of thoroughly occupying such points is obvious, as they afford an army on the defensive the means of passing readily and safely from one side to the other of the river, either to evade a force too powerful for it to cope with in the open field, or when an opportunity offers, from any imprudent movement of an invading force on one side, to throw itself suddenly from the other on its flank or rear, and thus forcing it to a retrograde movement. With respect to mountain-passes, the main roads alone will require permanent works. If the passes are independent of each other, a work will be necessary for each one separately; but where several unite at the same point, upon or within the frontier, a single work placed upon this point will suffice. Local circumstances will determine the point in each pass which, occupied, will offer the greatest advantage for obstructing the march of an invading force, and retarding the bringing forward its *matériel*. The only rule that can be given is that, whilst the position selected shall satisfy these conditions, there shall be every facility of communication between the fortress and the interior for receiving supplies and reinforcements. This rule would lead generally to the selection of some point of the outlet within the frontier as the proper one. In the case of important commercial cities and large naval depots lying within harbors more or less accessible both to sea and land attacks, the character of the defenses called for must necessarily be commensurate with the magnitude of the interests to be guarded, and the consequent temptation to an enemy to put forth great efforts for their occupation and destruction. The avenues of approach to these objects by sea, which can be brought within range of cannon and mortars in fortifications on the shore, or in casemated works erected on natural or artificial islands, should be occupied to a distance that will prevent a fleet from approaching near enough to open a bombardment, and if practicable also force the enemy, if he ventures a land-attack, to disembark his forces either at so great a distance from the object to be reached that he will not be able, by a sudden movement of this nature, to effect a surprise, or to limit his landing to such points on the coast as, from their exposed position, may render the co-operation of the naval and land forces very uncertain, and, in case of a storm, place the latter in a very perilous condition if attacked. These works will form the exterior chain of the defenses. Within these, batteries either open or casemated, as the locality may seem to demand, should occupy all the most suitable positions for sweeping the path that a fleet must follow by powerful cross, direct, and enfilading fires, and for reaching every point of anchorage within the harbor. On the land-approaches, points should be occupied by forts of a permanent character, which will prevent a sufficiently near approach to bombard the city or depot, and, in combination with temporary works, will afford an intrenched field of battle for the troops on the defensive. These will form the exterior line of the land-defenses, the interior line being either a continuous enceinte of permanent fortification, which will require a regular siege for its reduction, or else a suitable combination of either continuous or detached field-works of such strength and armament that the enemy, in any attempt to carry them by an open assault, will be made to suffer heavily even if he is not repulsed. The security of objects of this character will be greatly increased when they lie at some distance within the sea-coast frontier, and can only be approached by water through such comparatively narrow defiles as even our largest rivers present, and by land after one or more marches. These defiles will, for the most part, not only present admirable positions on their banks, from which an assailant's fleet can be enfiladed within the range of the heaviest guns, but frequently others, at points where the river narrows, or changes its course, where works occupying the opposite banks will give the means of rendering the river impassable by torpedoes, booms, rafts, or other floating and sunken obstructions, which cannot be removed except by getting possession of the defenses by which they are guarded, by a land-attack. In the great military States of Continental Europe, the question as to what extent the great centers of population and wealth in the *interior* should be covered by fortifications has been submitted to the investigation of the ablest engineers and statesmen, from the time of Vauban down to the present day. Whatever differences of opinion have been called forth as to the mode of accomplishing this object, as shown in the published views on the proposition to fortify Paris, there seems to have been none among those best qualified to decide upon it as to the great importance of so fortifying this Capital and other large places in the interior, as Lyons, etc., which from their position must be of the highest strategical value in the case of a successful invasion by a large army, as not only to prevent their wealth and resources from falling into the possession of the invading force, but to make them safe rallying-points for beaten and dispersed forces, and depots for organizing new armies. The plan that has been adopted for this end, both in France and in most of the other cities of Europe which have been either newly fortified or had their old works strengthened within this period, is to surround the city by a continuous enceinte of greater or less strength, but one secure from a *coup-de-main*, and to occupy with forts of a permanent character the most suitable points in advance of the enceinte, to prevent an enemy from bombarding the city, or penetrating between them without first gaining possession of them. By this plan it is proposed to gain all the advantages offered by the passive resistance of fortifications and the activity of a disposable movable force occupying the zone between the enceinte and the forts as an intrenched camp, upon which the forts with temporary works thrown up between them would render an open assault too perilous to be attempted. As to what future changes will be called for in permanent fortifications, both for inland and sea-coast defense, time alone can develop. Judging from the increasing size and range of cannon, and their greater destructive effects, it is probable that wrought-iron will have to be substituted for stone in positions where the latter is exposed to the heavy projectiles coming into use, as this material and earthen parapets will alone afford an indestructible cover against such projectiles. Still, when we look to the time and care which are given to the erection of permanent works, the great superiority they have over temporary structures for the planting and handling the heaviest cannon, besides the difficulty which the transportation of such enormous weapons offers to their use by the assailant, there is no reason why these changes should not inure to the advantage of the defense, both on land and water fronts. In the defense of harbors and rivers against the most imposing means of attack by heavily armed iron-clad steamers, there is every reason to suppose that adequate means will be found, in floating and stationary obstructions, like bombs and torpedoes, combined with iron-clad floating batteries, to secure them from all hazard. See *Fortification* and *Permanent Fortification.*

FRONT OF COUNTERGUARDS.—A certain number of counterguards so disposed as to mutually flank each other.

FRONT OF FORTIFICATION.—All the works constructed upon any one side of a regular polygon, whether placed within or without the exterior side. Some authors give a more limited sense to the term, by confining it to two half-bastions joined by a curtain.

FRONT OF OPERATIONS.—All that part of the theater of operations in front of the successive positions occupied by the army as it moves forward. See *Strategy.*

FRONT SIGHT.—A sight usually attached to the barrel, near the muzzle, by means of a horizontal screw at right angles to the barrel, which allows a horizontal motion to the right or left of the true position, which is marked by the 0 of the scale and vernier. To assure the vertical position of the sights, a level is attached to the rear of the front sight, and has a colored liquid, which renders the bubble more distinct to the marksman in aiming.

The shape of the sight proper is a subject about which there is much difference of opinion among marksmen, some preferring one variety and others another. Provision is made for the ready substitution of sight-pieces of different kinds. The drawings show some of the varieties most commonly used by the best marksmen. To avoid the reflection of the sun on the sights, they should be blackened with smoke, or, better, by lamp-black mixed with shellac varnish, and applied with a small brush. A shade made of metal or card-board, and painted black or dark green, incloses the end of the barrel for a distance of three inches. See *Sight.*

Front Sights.

FRUMENTARIUS.—A Roman soldier whose duty was to bring supplies of provisions to the army, and the earliest notice of all hostile movements. They were also, under the Roman Empire, officers who acted as spies in the Provinces and reported to the Emperor whatever seemed worthy of note. They appear to have derived this appellation from their gathering news in the same way that the Frumentarii or Purveyors collected corn.

FUEL.—This term is generally applied to combustibles used for the production of heat; also, less frequently, to combustibles such as oil, paraffine-oil, used for lighting. Under articles Coal, Coke, etc., will be found details of the physical properties and chemical composition of the various fuels; the following observations bear chiefly on their economical application as sources of motive power. The two elementary bodies to which we owe the heating powers of all our fuels, natural and artificial, are carbon and hydrogen. Coke, wood-charcoal, peat-charcoal, and anthracite contain little or none of the latter element, and may be regarded as purely carbonaceous fuels. But wood, peat, and most varieties of coal contain hydrogen as well as carbon; and in their combustion these two substances combine to produce volatile and combustible hydrocarbons, which are volatilized previous to being consumed, while a purely carbonaceous fuel evolves no volatile matter until combustion has been effected. These hydrocarbons are numerous and varied in composition; but when combustion is perfect, the amount of heat produced by any hydrocarbon is exactly what would have been produced had the hydrogen and carbon been burned separately. It will be of advantage, therefore, to study these two elementary combustibles in succession, in order to estimate subsequently the combined effect where they come together in the same fuel. The heating power of a combustible, or the *amount* of heat generated by it, is usually expressed in degrees Fahrenheit on so many pounds' weight of water. But in estimating the *temperature,* or intensity of heat produced, we have to keep in view that different substances have different capacities for heat—that of water being generally assumed as unity. The number expressing this capacity is called the specific heat of the substance. Water 1000, carbonic acid 221, imply that while 1000 units of heat are required to elevate the temperature of water any given number of degrees, only 221 units are required to elevate to the same temperature an equal weight of carbonic acid.

CARBON AS FUEL.—1. *Amount of Air required for Combustion.*—Burned in air, carbon combines with the oxygen to form carbonic acid (CO_2), mingled with nitrogen, the other atmospheric element. The chemical change may be thus represented, atomically:

			Products of Combustion.	
Carbon,		6.0		
Air (69.6)	Oxygen,	16.0	Carbonic acid,	22.0
	Nitrogen,	53.6	Nitrogen,	53.6
		75.6		75.6

Or, assuming carbon as unity:

Carbon,		1.000		
Air (11.6)	Oxygen,	2.667	Carbonic acid,	3.667
	Nitrogen,	8.933	Nitrogen,	8.933
		12.600		12.600

Carbon therefore requires about twelve times its own weight of air for perfect combustion.

2. *Amount of Heat Produced.*—Andrews found that 1 lb. carbon produced heat equal to 1° F. in 14,220 lbs. of water. Other observations agree very closely. This may be otherwise stated thus: 1 lb. carbon will raise from freezing to boiling point (32° to 212° = 180°) $\frac{14220}{180}$ = 79 lbs. water; from mean temperature to boiling-point (60° to 212° = 152°) $\frac{14220}{152}$ = 93.5 lbs. water; will boil off in steam from mean temperature (60° to 212° = 152°, add latent heat in steam 965° = 1117°) $\frac{14220}{1117}$ = 12.73 lbs. water; and will boil off in steam from boiling-point (latent heat in steam 965°) $\frac{14220}{965}$ = 14.74 lbs.

3. *Utmost Temperature or Intensity of Heat from Carbon.*—Here we suppose the combustion effected in a space inclosed by non-conducting material, so that all the heat produced by 1 lb. carbon is retained by the products of its combustion. Caloric sufficient to raise 14,220 lbs. of water 1° F. is thus compressed, as it were, into 12.6 lbs. of carbonic acid and nitrogen. To determine the temperature thus produced, we require to know the specific heat of this gaseous compound, that of water being 1.

3.667 lbs. carbonic acid.	Specific heat	2210
8.933 " nitrogen.	" "	2754
12.600 " products of combustion.	Mean sp. "	2596

14,220° on water at 1.000 specific heat will give 54,776° on these products per pound weight. Distributed over 12.6 lbs., this heat will raise the temperature to $\frac{54776}{12.6}$ = 4347° F., which is therefore the utmost intensity of heat attainable in burning carbon, supposing no loss by absorption or radiation.

4. *Effect of Excess of Air.*—Excess of air has been proved to have no effect on the *quantity* of heat produced where combustion is perfect; but the intensity of *temperature* is diminished. Suppose two equivalents of air admitted; we then have as the products of combustion—

3.667 lbs. carbonic acid.	Specific heat	2210
8.933 " nitrogen.	" "	2754
11.600 " air in excess.	" "	2669
24.200 " products.	Mean sp. "	2631

14,220° on water = 54,048° on this new mixture of gases. But the heat is now diffused over 24.2 lbs. matter instead of 12.6 lbs., $\frac{54048}{24.2}$ = 2347° F.: the utmost temperature produced by carbon burned in two equivalents of air. The utmost temperatures attainable, with various proportions of air, are given below, and also the appearance which the interior of the furnace would exhibit. Flame at these temperatures will present the same differences in color.

WEIGHT.		Ratio of Fuel to Air.	Highest Possible Temperature.	Appearance of a Body exposed to such Temperature.
Carbon.	Air.			
lbs.	lbs.			
1	11.6	1 to 1	4347°	Intensely brilliant.
1	17.4	1 " 1½	2951	Dazzling white.
1	23.2	1 " 2	2233	Bright ignition.
1	29.0	1 " 2½	1797	Full cherry red.
1	34.8	1 " 3	1503	Commencing cherry red
1	58	1 " 5	908	Incipient red.
1	69.6	1 " 6	758	Black.

5. *Effect of Deficiency of Air.*—If, before reaching the superior layers of carbon or cinder, the air has parted with all its oxygen to form carbonic acid with the production of heat, then the carbonic acid combines with part of the remaining carbon to form carbonic oxide, CO, but without producing heat. The loss may amount, therefore, to one half of the fuel: some have stated it as high as three fourths. If this oxide, when it gets above the fuel, meet with air before cooling, it burns with a pale blue flame, restoring part of the lost heat; but to what extent has not yet been determined.

6. *Effect of Water Present.*—Passing into a vapor, water absorbs both sensible and latent heat, and thus diminishes the temperature. Heating power is also lost, as products of combustion are generally passed into the atmosphere at a high temperature.

HYDROGEN AS FUEL.—1. *Air Required.*—Hydrogen combines with the oxygen of the air to form vapor of water, mingled with nitrogen:

			Products of Combustion.	
Hydrogen,		1.0		
Air (34.8)	Oxygen,	8.0	Vapor of water,	9.0
	Nitrogen,	26.8	Nitrogen,	26.8
		35.8		35.8

1 lb. hydrogen therefore requires 34.8 lbs. air, while 1 lb. carbon requires only 11.6 lbs.

2. *Amount of Heat Produced.*—The amount of heat produced from hydrogen is much greater than that from carbon; the caloric from 1 lb. heating 60,840 lbs. water 1° F. Part of this is, however, latent in the water-vapor, and must be deducted in calculating intensity of heat, and also heating effect under all ordinary circumstances. This deduction amounts to 9 lbs. water × 965° latent = 8685°, leaving 52,155° as the effective heating power of 1 lb. hydrogen.

3. *Utmost Temperature or Intensity of Heat.*—This is *less* than in the case of carbon, in consequence of the high specific heat and greater quantity of the products. We have—

Vapor of water........	9 lbs.	Specific heat	8470
Nitrogen...............	26.8 "	" "	2754
	35.8 "	Mean sp. "	4191

52,155° on water will be 124,445° on these products; and $\frac{124445}{35.8}$ lbs. = 3476° is the utmost possible temperature.

4. *Effect of Excess of Air.*—As in the case of carbon, the intensity of heat is diminished, as under:

Weight. Hydrogen.	Weight. Air.	Ratio of Fuel to Air.	Highest Possible Temperature.
lbs.	lbs.		
1	34.8	1 to 1	3476°
1	69 6	1 " 2	2187
1	104.4	1 " 3	1591
1	139.2	1 " 4	1250

5. *Effect of Deficiency of Air.*—No new product is the result of deficiency of air, as in combustion of carbon; the hydrogen simply escapes unconsumed.

6. *Effect of water-vapor present* is diminution of intensity and ultimate loss of heat in application, as in the case of carbon.

Temperature of Ignition of Carbon and Hydrogen.—These substances must be themselves heated before they can burn. Hydrogen begins to burn at or below 300°, while carbon requires a red heat (800° to 1000° F.), and even at that temperature burns very slowly. Consequently, where they are combined, as in common coal, the temperature present is often sufficiently high to ignite and consume the hydrogen, while the carbon remains unchanged as cinder or passes away as smoke, unconsumed in either case. All that has been said above of carbon, as to air required, heating power or value, utmost temperature, temperature of ignition, effect of water present, and of excess or deficiency of air, applies without modification to one class of fuels—the purely carbonaceous, including anthracite, coke from coal, charcoal from wood and peat, and the cinder of any description of fuel. The incombustible ash must be allowed for in calculating heating power or value; and also the volatile bodies—nitrogen, sulphur, etc.—the latter of which frequently renders the fuel unsuitable for many purposes in the arts and manufactures. Peat, wood, and coal, with the exception of anthracite, contain hydrogen to an extent rarely exceeding 5 per cent. We have seen that, compared with carbon, hydrogen requires three times as much air, and generates nearly four times as much heat, but produces 20 per cent less intensity of heat, and ignites at a much lower temperature; and the combustion of wood, coal, etc., is in these respects modified according to the proportion of hydrogen present in them. The following table shows the composition of British coal, as determined by Playfair and De la Beche. Columns 8 to 12 are added to illustrate the process of combustion.

The elements of a hydrocarbon are consumed, not simultaneously, but in succession. First, the carbon is separated from the hydrogen in light floating particles, subsequently seen as soot or smoke (if not consumed); then the hydrogen burns, and communicates heat to the carbon particles, which then appear as flame. The color of the flame indicates the temperature present; and if the temperature is sufficiently high, the carbon of which the flame is composed burns also, producing a further increase of heat. If not, the flame, as it moves onward, cools, becoming red, dull red, and finally black and smoky, passing away as such. For complete combustion of common coal, we therefore require not only air in sufficient quantity, but also intensity of heat above the fuel. We require a low temperature to separate the carbon from the hydrogen; a higher temperature to consume the hydrogen; and a still higher to consume the carbon of the flame. In closed furnaces, such as those of steam-boilers, while the current of air supplied continues pretty uniform in quantity, the volatile bodies are evolved almost immediately after fueling; and would require, for the moment, perhaps four times the quantity of air which is passing through. The volatile fuel is, in consequence of the want of air, carried off partly unconsumed; and the temperature in such furnaces is frequently too low for the ignition of carbon, as may be seen from the color of the flame; the cold boiler having abstracted the heat before the flame has been subjected to its influence. From the principles involved, we should expect most success where the fuel is supplied by mechanical arrangements as regularly and uniformly as the air, and where, in addition, the body of the furnace is protected or removed so far from boiler-surface and all other cooling agents as is necessary to maintain a temperature within it sufficient for the thorough ignition of the flame. See *Cupola-furnace*.

FUGLEMAN.—An intelligent soldier posted in front of a line of men at drill, to give the time and an example of the motions in the manual and platoon exercises. He originally stood in front of the right wing, and hence the name. The word is frequently written *Fugelman*, and more properly *Flugelman*, from the German *flügel*, a wing.

FULCRUM.—The cast-iron post at the breech of a large cannon used as a support for an iron bar in giving elevations; called also *ratchet-post*. See *Lever*.

FULL BASTION.—When the interior is filled up to the level of the terre-plein of the rampart, the bastion is called *full*. See *Bastion*.

FULL CHARGES.—The charges of powder required

When coal is heated in a retort, it yields volatile hydrocarbons amounting to 20 to 32 per cent of its weight (see column 11). The hydrogen has robbed the fuel of six times its own weight of carbon. When fresh fuel is added to live coal in a furnace, the same result ensues; so that in using coal, 50 to 67 per cent of carbon burn on the grate, and 20 to 32 per cent carbon and hydrogen have to be burned in the open space above the fuel, or escape unconsumed.

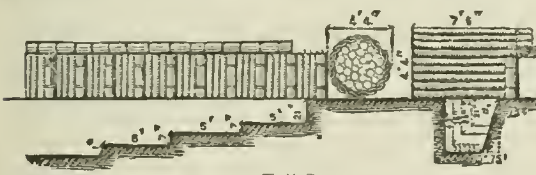
in actual service to produce the best or most useful effect. See *Charge*.

FULLER'S EARTH.—A mineral consisting chiefly of silica, alumina, and water, with a little magnesia, lime, and peroxide of iron. The silica is about 50, the alumina 20, and the water 24 per cent of the whole. It is regarded as essentially a hydrous bisilicate of alumina. It occurs in beds, associated with chalk, oölite, etc.; is usually of a greenish-brown or a slate-blue color, sometimes white; has an uneven earthy fracture and a dull appearance; its specific gravity is from 1.8 to 2.2; it is soft enough to yield readily to the nail; is very greasy to the touch; scarcely adheres to the tongue; falls to pieces in water, but does not become plastic. It has a remarkable power of absorbing oil or grease; and was formerly very much used for fulling cloth, for which purpose it was considered so valuable that the exportation of it from England was prohibited under severe penalties; it is still used to a considerable extent. The annual consumption in England is said to have at one time exceeded 6000 tons. It is found at Nutfield, near Reigate, in Surrey, in cretaceous strata; where there are two distinct beds, the upper one of a greenish color, and 5 feet thick, resting on the other, which has a bluish tint, and is 11 feet thick. It is also found in Bedfordshire, Nottinghamshire, and Kent; and on the Continent in Saxony, Bohemia, and near Aix-la-Chapelle. There is a considerable deposit of it at Bath, where the group of associated blue and yellow clays and marl has received the name of "The Fuller's Earth Series." It is also found at Maxton, in Scotland.

FULL PAY.—The full amount of an officer's or soldier's pay, as fixed by law. In the British service, an officer of thirty years' full pay is permitted to retire on the full pay of his regimental rank, with a rank one step higher than that which he holds by brevet or otherwise.

FULL REVETMENT.—Any revetment is said to be *full* when the wall is carried up to the superior slope of the parapet.

FULL SAP.—The full sap is resorted to, in siege-operations, when the fire becomes so destructive that the flying sap cannot be used. The trench is opened and pushed forward by engineer troops alone; for this purpose a working-party, termed a *brigade*, of eight sappers, is requisite. The brigade is divided into two equal *sections;* the sappers of the first section dig the trench, and are numbered from 1 to 4, No. 1 leading. The other four are termed *assistants;* they bring forward the materials, and assist the first section in all the necessary operations. The leading sapper, No. 1, is provided with a pick and shovel,



Full Sap.

and wears a musket-proof helmet and cuirass; he works on his knees, being covered, on his side toward the defenses, by the parapet of the trench, from which he debouches; and in front by a sap-roller, which is placed perpendicular to the line of direction on which he is to work, and rests against the gabion he is filling, covering it one foot. The portion of the sap which he digs is 21 inches wide at top and 21 inches deep; it receives a slope of 4 perpendicular to 1 base on the front, and is vertical in the rear; and its length is 5 feet. So soon as this portion is finished, No. 2, who is protected in all respects like No. 1, commences to widen and deepen the trench 8 inches at the point from which No. 1 started, and follows on after No. 1, keeping always 5 feet in his rear. When No. 2 has pushed forward 5 feet, No. 3 commences and enlarges the trench in each direction 7 inches; he follows on also 5 feet in rear of No. 2; but as the work thrown up by the sappers preceding him affords pretty good cover, he can work standing, taking the precaution to bend forward for greater security. Finally, No. 4 begins when No. 3 has got on 5 feet, and deepens and widens 7 inches. As he is well covered he can work in an unconstrained posture. Besides the shelter given on the flank by the gabions, as they are successively filled, and by the sap-roller in front, the further precaution is taken of driving sap-fagots along the berm, at the junction of the gabions; these are successively removed as they are no longer requisite. The trench-fascines are placed upon the gabions by the assistants; and the remainder of the trench completed by working-parties of the line, so soon as the brigade of sappers have proceeded far enough for the others to commence without hindrance. See *Sap.*

FULL SIGHT.—An aim in which the entire fore sight is seen when looking through the notch on the rear sight. See *Sight.*

FULMINATE OF MERCURY.—Fulminating-mercury ($2HgO,C_4N_2O_2$) is best prepared by dissolving 3 parts of mercury in 36 of nitric acid of specific gravity 1.34, without the application of heat, in a flask capable of holding 18 times the bulk of the acid. The solution is then to be poured into a large vessel containing 17 parts of alcohol of a specific gravity 0.830, and immediately to be re-transferred to the flask, which is still full of nitrous vapors, and with which it must be well shaken in order to effect their absorption. Effervescence commences after a few minutes, and soon becomes extremely violent; and at the same time there is a deposit of metallic mercury, which is gradually re-dissolved. The reaction must be moderated by the gradual addition of 17 parts more of alcohol; and on cooling, crystals of the fulminate, amounting to 4.6 parts, are deposited. These must be washed with cold water, and dried at 100° F. Fulminate of mercury forms white silky needles.

This is the composition used in the detonating primers employed for the ignition of dynamite and gun-cotton. It is the substance in percussion-caps that detonates and produces fire when the cap is struck a sharp blow. Dry fulminate of mercury explodes violently when heated to 367° F., by the electric spark, or when struck. When wet it is inexplosive, and therefore it is always kept wet, being dried in small amounts when required for use. Great care is requisite in handling it. For the purpose of detonating nitro-glycerine or its preparations 15 grains of the fulminate are sufficient, but to detonate gun-cotton 25 grains are necessary. The fulminate in detonating fuses should be inclosed in a copper case or cap, and must never be loose. The fulminate should be wet when charging the detonators, and afterwards dried.

FULMINATE OF SILVER.—Fulminating-silver ($2AgO,C_4N_2O_2$) is prepared in nearly the same manner as the fulminate of mercury. It is more powerfully explosive than the last-named salt. Even when moist or under water, pressure with a hard body will cause its explosion; and when quite dry, the slightest friction between two hard bodies produces a similar result. The preparation of the fulminates is attended with very considerable danger, and should be attempted by none but professed chemists.

FULMINATES.—All the fulminates are easily exploded, and some are excessively sensitive; the *mercury salt* is the only one of practical value.

The explosive force of the fulminate of mercury is not much greater than that of gunpowder, on account of the small amount of gas given off, but it is much more sudden in its action, and the effect is of a local character. When dry, a violent explosion is produced by a blow; by a heat of 186° (366.8° F.); by contact with some strong sulphuric or nitric acid; by sparks from flint and steel; or by the electric spark. If wet, it is inexplosive.

Fulminate of mercury is formed by the action of mercuric nitrate and nitric acid upon alcohol. One part of mercury is dissolved in 12 parts of nitric acid, and the solution poured into 11 parts of alcohol. The vessel is placed in hot water until the mixture it contains darkens, becomes turbid, and begins to evolve dense white fumes. It is then removed from the water. The reaction is allowed to go on till the liquid clears and the dense white fumes cease; further action is then stopped by filling up with cold water. Should red fumes appear during this operation, cold alcohol must be added to check the violence of the action. The fulminate settles to the bottom of the vessel as a gray crystalline precipitate. The liquid is then poured off, and the fulminate washed several times by decantation or upon a filter.

Fulminate of mercury is used only for igniting other substances. It is employed mainly in percussion-caps, primers, fuses, detonators, etc. It is of special importance from its power to cause the violent explosion called detonation; it has thus become a requisite for exploding gun-cotton, nitro-glycerine, and preparations made from them. The fulminate in a detonating fuse should be contained in a copper case, and must not be loose; on account of danger, it is necessary that it be charged wet.

In the application of fuses to the detonation of modern explosives, some very surprising facts have recently been established which go far to induce a belief that synchronism in vibration is an important element. Thus, compressed gun-cotton may be detonated by 5 grains of fulminating mercury, but requires 50 grains of chloride of nitrogen; it fails with 100 grains of iodide of nitrogen, and even with 124 grains of nitro-glycerine, though the latter develops far more heat and mechanical force. On the other hand, a small initial charge of gun-cotton readily detonates nitro-glycerine. See *Explosive Agents*.

FUMIGATION.—To correct and purify an infectious or confined atmosphere, such as is often found in transports, fumigations are necessary. The materials recommended for the purpose are brimstone with sawdust; or niter with vitriolic acid; or common salt with the same acid. One fluid ounce of sulphuric acid mixed with two fluid ounces of water, and then poured over four ounces of common salt, and one ounce of oxide of manganese in powder, these latter ingredients being previously placed in hot sand, are also recommended. Burning charcoal is also a good disinfectant.

FUNCTIONS.—A mathematical term of frequent occurrence in the solutions of the problems of gunnery. When two or more variables are combined with constants in an equation, and are such that a change of value of one implies a corresponding change of value of one or more of the others, then such variables are said to depend on and to be functions of each other; and the expression of the mode of dependence is said to be a *function* of such variables. If such an expression involves but one variable, it is said to be a function of one variable; if two are involved, to be a function of two variables; and so on. Thus $\sin x$, e^{ax}, $\log x$, $\sqrt{a^2 - x^2}$, are functions of one variable—viz., of x; e^{ax+by}, $\tan(ax + by)$, x^y, are functions of two variables, x and y; so xyz, $x^2 + y^2 + z^2$ are functions of three variables; and so on. Functions are denoted by the symbols F, f, φ, ψ, etc. Thus $F(x)$ means a function of one variable, x combined with constants or not, as the case may be; $\psi(xyz)$, a function of three variables. These functional symbols are *general*, and their specific forms are the particular functions which arise from operations in algebra, trigonometry, etc.

Functions are implicit and explicit. When one variable is expressed in terms of others, it is said to be an explicit function of them; but when all the variables remain involved in one expression, the function is said to be implicit. Thus, $x^2 + y^2 - r^2 = 0$ is an implicit function of two variables, but $y = \sqrt{r^2 - x^2}$ is an explicit function of one variable. In explicit functions, the variable which is expressed in terms of the others is called the *dependent* variable, and the others the *independent* variables. Explicit functions are usually written in the form $z = f(xy)$; implicit, in the form $u = F(xyz) = 0$. Functions, again, are algebraical or transcendental. Algebraical functions are those which involve the operations of addition, subtraction, etc., and of involution and evolution. Transcendental functions are those where the operations symbolized are such as e^x, $\log_e x$, $\sin x$, etc.—i.e., exponential, logarithmic, or circular. Functions, also, are simple or compound according as they involve one or several operations. $y = \sin x$ is a simple function; but $y = \log \sin x$ is compound. Further, functions are divided into the continuous and the discontinuous, the circulating and the periodic. Continuous functions are such as are subject to the following conditions: 1. As the variable gradually changes, so the function must gradually change; 2. The law symbolized by the functional character should not abruptly change. Circulating functions are those whose values lie within certain limits for all values of the variables. $y = \sin x$ is an example at once of a continuous and of a circulating function. A function is said to be periodic when it assumes the form $f^n(x) = x$, signifying that if on x a certain operation f be performed n times, the resulting value will be x. Thus $f(x) = \frac{1}{1-x}$ is a periodic function of the third order. For performing the operation indicated by f the second time on $\frac{1}{1-x}$ as the variable, we have $f^2(x) = \frac{1}{1 - \frac{1}{1-x}} = -\frac{1-x}{x}$; and the third time we have $f^3(x) = \frac{1}{1 - \left(\frac{1-x}{x}\right)} = x$. The functional calculus is a recent growth of the transcendental analysis. The object of the differential calculus is generally to ascertain the changes in functions arising from the continuous and infinitesimal variation of their subject variables. The object of the new functional calculus is, speaking generally, to investigate the forms of functions and their growth, when they are subject to a continuous and infinitesimal change as to form. According to Mr. Price (Treatise on the Infinitesimal Calculus), as the differential calculus investigates properties of continuous numbers, so does the new calculus the properties of continuous functions; and as there is an integral calculus of numbers, so there is an inverse calculus of functions. Of the new calculus, the calculus of variations may be regarded as the main branch. It includes, of course, the subject of functional equations. Functional equations are those in which it is required to determine from equations the forms of the functions entering them.

FUND.—There are several kinds of *Funds* in the United States service, arising from certain savings and assessments, and expended according to certain laws. See *Company Fund*, *Post Fund*, and *Regimental Fund*.

FUNERAL HONORS.—On the receipt of official intelligence of the death of the President of the United States, at any post or camp, the Commanding Officer on the following day causes a gun to be fired at every half-hour, beginning at sunrise and ending at sunset. When posts are contiguous, the firing takes place at the post only commanded by the Superior Officer. On the day of the interment of a General-in-Chief, a gun is fired at every half-hour until the procession moves, beginning at sunrise. When the funeral of an officer entitled, when living, to a salute takes place at or near a military post, minute-guns are fired while the remains are being borne to the place of interment; but the number of such guns is not to exceed that which the officer was entitled to as a salute when living. After the remains are deposited in the grave, a salute corresponding to the rank of the deceased officer is fired in addition to three salvos of artillery or three volleys of musketry. In the event of a Flag Officer of the Navy, whether of the United States or of a foreign country, dying afloat, and the remains are brought ashore, minute-guns are fired from the ship while the body is being conveyed to the shore. If it be in the vicinity of a military post, the flag of the latter is displayed at half-staff, and minute-guns are fired from the post while the procession is moving from the landing-place. These minute-guns are not to exceed in number that which the officer was entitled to as a salute when living. During the funeral of a civil functionary entitled, when living, to a salute, the flag is displayed at half-staff, and minute-guns fired as before; but neither salute nor salvos are fired after the remains are deposited in the grave. On the death of an officer at a military post, the flag is displayed at half-staff, and kept so, between the hours of reveille and retreat, until the last salvo or volley is fired over the grave, or, if the remains are not interred at the post, until they are removed therefrom. During the funeral of an enlisted man the flag is displayed at half-staff, and is hoisted to the top after the final volley or gun is fired. All military posts in sight, or within six miles of each other, display their flags at half-staff upon the occasion of either one doing so. The same rule is observed towards a vessel of war. On all occasions where the flag is displayed at half-staff it is *lowered* to that position from the top of the staff. It is afterwards *hoisted* to the top *before* being finally lowered.

Funeral escorts are allowed as follows: *General Commanding-in-Chief*, a regiment of infantry, a battalion of cavalry, and two batteries of artillery; a *Lieutenant General*, a regiment of infantry, a battalion of cavalry, and a battery of artillery; a *Major General*, a regiment of infantry, two companies of cavalry, and a battery of artillery; a *Brigadier General*, a regiment of infantry, a company of cavalry, and a platoon of artillery; a *Colonel*, a regiment; a *Lieutenant-colonel*, six companies; *Major*, four companies; *Captain*, one company; *Subaltern*, half a company; *Non commissioned Staff Officer*, and a *Sergeant*, sixteen privates, commanded by a Sergeant; *Corporal*, twelve privates, commanded by a Corporal; *private*, eight privates, commanded by a Corporal. An officer's escort, when practicable, is commanded by an officer of the same grade. The escort is formed with the center opposite the tent or quarters of the deceased; arms at a carry; bayonets unfixed; the band on that flank of the escort towards which it is to march. Upon the appearance of the remains, the Commander commands: 1. *Present*, 2. ARMS, and the band plays an appropriate air; arms are then carried, after which the coffin is taken to the flank of the escort, opposite the music. The escort is next wheeled into column of companies, platoons, or fours. If the escort be small, it may be faced by the flank. The procession is formed in the following order: 1. Music; 2. Escort; 3. Clergy and Surgeons; 4. Remains and Pall-bearers: 5. Mourners, including members of the former command of the deceased; 6. Distinguished persons, according to rank; 7. Delegations; 8. Societies; 9. Citizens. The procession being formed, the Commander of the escort commands, 1. *Reverse*, 2. ARMS, and then puts the escort in march. The escort marches in slow time to solemn music; the center of the column having arrived opposite the grave, line is formed facing it. The remains are next brought and placed over the grave, after which arms are presented, the band playing an appropriate air. The music having ceased, arms are *carried*, and the coffin, by direction of the Commander of the escort, is lowered into the grave. The Commander next commands: 1. *Rest on*, 2. ARMS. The funeral services are now completed, after which the Commander commands: 1. *Carry*, 2. ARMS, 3. *With blank cartridges*, 4. LOAD. He then causes the escort to fire three rounds with blank cartridges, the muzzles of the pieces being elevated. The escort is then formed into column, and marched to the point where it was assembled, and is then dismissed. The band does not play till it has left the inclosure. When the distance to the place of interment is considerable, the escort, after having left the camp or garrison, may march in route-step until it approaches the burial-ground, when it is called to attention and the arms reversed. The music does not play while at route-step. In all funeral ceremonies, six pall-bearers may be selected from the grade of the deceased, or the grades next above or below it. If a Commissioned Officer, the coffin is borne by six Non-commissioned Officers; if a Non-commissioned Officer, or private, by six privates. At the funeral of a General Officer, the Commander of the escort, in forming column, gives the appropriate commands for the cavalry, artillery, and infantry, which form in column, from front to rear, in the order named. The trumpeters or field-music sound a march, flourishes, or ruffles, according to the rank of the deceased, whenever arms are presented, after which the band plays an appropriate air. In marching to the cemetery, the trumpeters of the artillery and cavalry may alternate, in playing, with the band of the infantry. If the funeral be for a Mounted Officer, his horse, in mourning caparison, follows the hearse. Should the entrance to the cemetery prevent the hearse from accompanying the escort till the latter halts at the grave, the column is halted at the entrance long enough to take the remains from the hearse, when the column is again put in march. The cavalry and artillery, when unable to enter the inclosure, wheel out of the column, face to the column, and salute the remains as they pass. When necessary to escort the remains from the quarters of the deceased to the church, before the funeral service, arms are presented upon receiving the remains at the quarters, and also as they are borne into chapel. The Commander of the escort, previous to the funeral, gives the clergyman and pall-bearers all needful directions.

The usual badge of military mourning is a piece of black crape around the left arm above the elbow, and also upon the sword-hilt, and is worn when in full or in undress. As family mourning, crape is worn by officers (when in uniform) only around the left arm. The drums of the funeral escort are covered with black crape or thin black serge. See *Honors paid by Troops*.

FUNNEL.—An implement formed of sheet-copper and used for pouring the charges from the powder-measure into the shell. It is of the ordinary shape, the upper edge being turned over, outwards, to slightly stiffen it.

FURLOUGH.—A term usually applied to the absence with leave of non-commissioned officers and other enlisted men, granted at the discretion of the Commanding Officer. In the British service, the term is very generally used in India when a servant of the government proceeds on leave out of the country. The English furlough-pay is as follows: An officer drawing staff pay in addition to the pay of his rank is allowed 50 per cent of his substantive appointment; but in no case can the absentee draw more than £1000 per annum. Officers not on staff duty in India receive half the Indian pay of their rank; but in no case do they receive less than the minimum of £250 per annum.

In the United States, under authority of the 11th Article of War, furloughs for twenty days may be granted by the Commanding Officer of the post or the Commanding Officer of the regiment actually quartered with the portion of it to which the soldier belongs. Furloughs may be prohibited at the discretion of the Officer in Command. They are not granted to soldiers about to be discharged.

A Department Commander may grant furloughs to enlisted men for two months; a Military Division Commander for three months, or he may extend to three months a furlough granted by a Department Commander under his command. The General of the Army may grant furloughs not to exceed four months, or extend to four months a furlough already granted.

Furloughs are not granted by any Commanding Officer to go beyond the limits of the next highest command. To warrant a soldier in going beyond such limits the sanction of the superior authority must previously be indorsed on his furlough. A furlough must have the approval of the Secretary of War to enable the soldier to go beyond the limits of the United States. The prescribed limits are stated in the furlough, and if exceeded the man is liable to arrest and the revocation of his furlough.

In cases of special urgency, where it seems most judicious, and the applicant can show sufficient cause for his inability to pay his own expenses, Department Commanders, in the exercise of a sound discretion, may order transportation tickets to be purchased by the Quartermaster for furloughed soldiers, and where this is done a report of the amount paid for such transportation is made by letter to the Company Commander, who charges the same against the soldier's pay on the next muster-day.

Soldiers on furlough are not permitted to take with them their arms or accouterments.

No payments can be made to enlisted men on furlough, on their descriptive lists, without special authority from the Adjutant General.

The following is the form of a furlough:

To all whom it may concern:

The bearer hereof, ——— ———, a Sergeant (Corporal or private, as the case may be) of Captain ——— ——— company, ——— regiment of ———, aged — years, — feet — inches high, —— complexion, —— eyes, —— hair, and by profession a ———; born in the ——— of ———, and enlisted at ——, in the —— of ———, on the — day of ———, eighteen hundred and ———, to serve for the period of ———, is hereby permitted to go to ———, in the county of ——, State of ———, he having received a furlough from the —— day of ——— to the —— day of ———, at which period he will rejoin his company or regiment at ———, or wherever it then may be, or be considered a deserter.

Subsistence has been furnished to said ——— ——— to the —— day of ———, and pay to the —— day of ———, both inclusive.

Given under my hand at ——— this —— day of ———, 18—.
[Signature of the officer giving the furlough.] ——— ———.

See *Leave of Absence.*

FURNACE.—A contrivance for the production and utilization of heat, for warming, ventilating, cooking, and for manipulation of metals and liquids in the arts. Calcining-furnaces are those in which the solid fuel is mixed with the matters to be heated. Crucible-furnaces are used for melting steel or brass, and the furnace itself is embedded in the mass of heating fuel. Forge-furnaces are such as are in ordinary use by blacksmiths, merely a combination of draught and blowing from a bellows. Blast and cupola furnaces are used in the smelting of iron and other ores, and the fusing of hard metals. In these the stuff to be melted and the fuel are charged in combination in the upper end of a vertical cylinder, and the combustion is produced by air forced in at the bottom. Flame-furnaces are of varied form and character. Their effect is obtained by bringing a flame or current of highly heated gas into contact with the thing to be acted upon, instead of imbedding the substance with the fuel. The well-known reverberatory furnace, with fire-grate, flume-chamber, etc., is so arranged that by means of a low arched roof the flame is reverberated or turned back upon the material to be operated upon. Gas-furnaces have recently come into use; there are five or six different kinds. There are furnaces for burning powdered fuel, for natural gas, and for petroleum. Furnaces are also very largely used in glass-making, and in metallurgy and iron-manufacture.

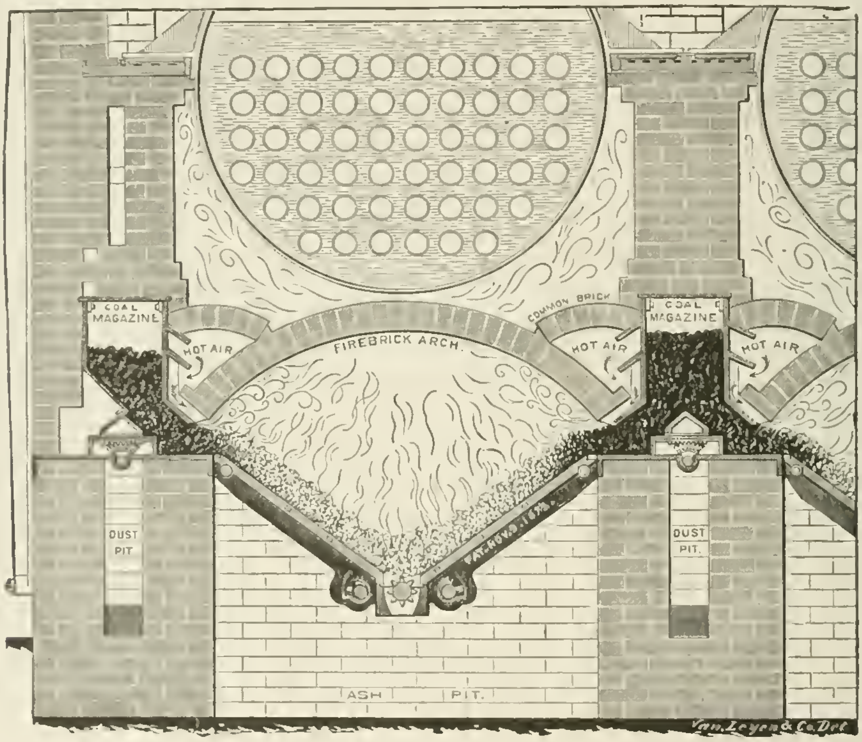


Fig. 1.

The most perfect and satisfactory furnace for general armory and laboratory use is known as the Murphy Smokeless Furnace, and shown in section in Fig. 1. Unlike other furnaces, the more it is crowded the more perfect combustion. The grates are kept constantly in motion, the clinkers cannot form upon them, hence air always passes between them and keeps them cool. The furnace is especially adapted to the use of fine or slack coal, which is put into large hoppers or magazines. By referring to the drawing, there will be seen a casting resting on the brick-work. This is a coking-plate. The inclined grates rest against it at their upper ends. On this plate is placed the inverted open box, called the stoker box. It has a ratchet in each end; a shaft, worked from the outside, has a section of a pinion

[illegible]

VI- 354.

fitted to each ratchet, moving the stoker-box back and forth on the coking-plate every six, ten, or fifteen minutes, as may be required. These stoker-boxes push the coal on to the edge of the coking-plate and grates; the coal then slides down toward the center of the furnace by its own gravity. The triangular piece above the box moves out and in by a lever from the outside, which divides the coal and helps bring it down in front of the stoking-boxes. Immediately over the coking-plates and on the side of each magazine is the arch-plate, on which the fire-brick arch rests. Where the brick come in contact with the plate there are ribs about an inch apart on which the brick are placed. This leaves a small space between each rib. Air is admitted in front of the furnace, regulated by a damper; it passes up through a flue in the brick wall, then over the arch, and there takes up the heat from the brick-work, passes down through the little openings and gives to the fresh fuel on the coking-plate its supply of air; not only that, but it is hot enough in itself to ignite any gases evolved, consequently immediate combustion takes place, and no smoke is made. By the time the coal reaches the grate the bituminous part is consumed, and what remains is coke. This gets its needed supply of air through the grates. Less than a one-horse-power engine is placed at the side; to this is attached a bar running across the front of the furnace. This bar is connected by links to arms which move the stoking apparatus, shake the grate-bars, and, if desirable, the clinker-breaker can be connected in the same manner.

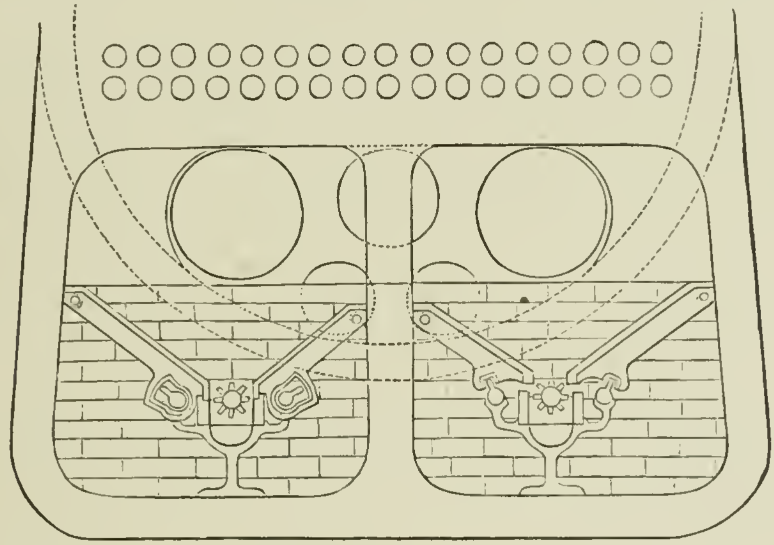

Fig. 2.

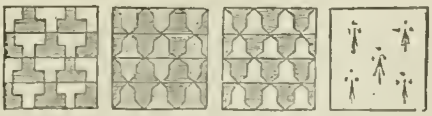
The operation of the grates is very simple and effective. Fig. 2 shows their arrangement in a recent United States Government test. The whole apparatus consists of an inclined shaking grate combined with a clinker-crusher and refuse-remover. The purpose of this combination is, without opening the furnace-door or using fire-tools, to keep the fires free of ashes and holes, to crush the clinker into small pieces, and to remove from the furnace all refuse, whether ash or clinker, resulting from the combustion of the coal, these operations being performed by simply working levers placed outside the furnace. This is effected by arranging the grate-bars at right angles to, instead of parallel with, the length of the furnace, inclining them so as to form a hopper, and making the alternate bars stationary and vibrating, the latter being pivoted at their upper ends upon the upper ends of the former, and vibrated up and down by means of a continuous feather on a horizontal bar lying lengthwise the furnace in pillow-blocks at the front and back of the furnace, and moved forward and back on its axis by a lever attached to an end protruded from the ash pit into the fire-room. At the bottom of this grate, and entirely independent of it, is a horizontal bar lying lengthwise the furnace in pillow-blocks, bristling with projecting teeth, and capable of being either vibrated forward and back or revolved entirely around its axis by a lever attached to an end protruded from the ash-pit into the fire-room. This is the clinker-crusher and refuse-remover. The crushing is done by the teeth of the vibrating or revolving bar, and the removing is done by the same process at the same time, the entire refuse falling from the furnace between the lower edge of the inclined grate and the side of the crusher along the lengthwise center of the ash-pit. The drawing shows the crusher-bar placed nearly but not exactly at the center, the grate forming two planes, one on each side of this bar, inclining from the horizontal at an angle of 45°, or forming a right angle with each other. The inner shape of the whole apparatus is that of a *hopper* with vertical ends, or, more nearly, that of an ordinary *hod*. A simple arrangement is for the grate to consist of only one inclined plane extending nearly across the furnace, instead of two inclined planes, each extending across nearly half of the furnace, and for the crusher to be placed against one side of the furnace, thus dispensing with one of the vibrating bars. See *Cupola-furnace* and *Iron*.

FURS.—In Heraldry, shields being often covered with the skins of wild animals, on which the fur was left, there came to be certain kinds of fur which were used in coat-armor, as well as in trimming and lining the robes of knights and nobles, and the mantles



Potent. Counter-vair. Vair. Ermine.

which were represented as surrounding the shields. The principal heraldic furs are: 1. Ermine of which the field is white, and the spots black; 2. Ermines of which the field is black and the spots white; 3. Erminois, which has the field gold, with black spots; 4. Vair, which consisted of pieces of the shape of little glass pots. It is said that the furriers used such glasses to whiten furs in, and because they were commonly of an azure (blue) color the fur in question came to be blazoned *argent* and *azure*; whilst counter-vair, in which the cups are represented as placed base against base, in place of edge to base, as in vair, was *or* and *azure*. 5. Potent and counter-potent, which are supposed to resemble the heads of crutches, placed differently, but having the same tinctures—viz., azure and argent.

FUSE.—Fuses for projectiles may be classified as time-fuses, percussion-fuses, and combination-fuses. The *time-fuse* serves to explode a projectile during flight, or at the end of a given period of time after its discharge from the gun. The *percussion-fuse*, rifled guns, serves to explode projectiles at the instant of striking a resisting object. The *combination-fuse* serves to explode a projectile either during flight or on impact.

TIME-FUSES.—The time-fuse is composed of a column or ring of fuse-composition, driven or pressed into a suitable metal, wood, or paper case. The proportions of the composition vary according to the time it is intended to burn. The service time-fuses comprise three varieties, viz., *wooden-case mortar-fuses*, *metal-case* (Bormann) *fuses*, and *paper-case fuses*.

Fuses for Mortar-shells.—The hard, close-grained woods are best adapted for making fuses; beech or ash is generally used. It should be dry, sound, free from sap, knots, worm-holes, or shakes. To turn the fuse-plug, a helper saws the plank into lengths equal to that of the fuse, and then into prisms, taking off the edges, and centering it on each end. The turner puts the fuse-plug thus roughed out in the lathe, turns its exterior, and graduates it, by means of a steel gauge, into inches and tenths of an inch, commencing at the bottom of the cup. When a number have been turned, the turner puts each fuse-plug into a chuck, bores it, and makes the cup with a tool for that purpose. The fuse-plugs should be carefully inspected, and verified with gauges, and those rejected which have splits, knots, or worm-holes, or which have not the proper dimensions. One turner can turn 500 fuse-plugs, or turn and bore 250, in ten hours.

The following utensils are required for driving the fuses: *driving-blocks*, with holes of the size of the fuse-plug; *benches; mallets*, for the 13-inch, 10-inch, and 8-inch fuses weighing 1 pound, for smaller fuses weighing ½ to ¾ pounds; *steel drifts*, shod with copper, the shortest with a mark .2 inch from the end, *copper ladles*, to contain sufficient composition to make a height, when driven, equal to one diameter of the bore; *copper pans; brushes*.

The composition for 8- and 10-inch light mortar-fuses is 2 parts of niter, 1 of sulphur, and 3 of mealed powder; for 10- and 13-inch heavy mortars, 2 of niter, 1 of sulphur, and 2¼ of mealed powder. The composition must be thoroughly ground and mixed with a muller, or in a leathern barrel, with brass balls. The time of burning will vary according to the quality of the materials used (especially of the mealed powder) and the degree of their admixture. Trials should be made with each composition by driving several fuses and getting their time of burning. There should not be any great variation in the times of burning of the different fuses of the same composition. Fuse-composition should be prepared only a short time before being used, and should be preserved in close vessels in a dry place.

When driving, the workman is seated, his driving-block in front of him, and a bench to hold a pan of composition at his right hand. He takes a fuse, cleans it of all foreign matter, inserting the drift to the bottom of the bore. He then drops the fuse-plug into the driving-hole, takes a ladleful of composition, passing the drift along the edges of the ladle to strike off the surplus; pours the composition into the fuse-plug, strikes it two gentle blows with the mallet, inserts the drift, pressing it down on the composition, giving the fuse two slight blows to settle the composition. The workman strikes the drift twenty-one blows in volleys of three, raising the mallet about one foot each blow, and moving the drift after each volley. He puts in another ladleful, and continues as for the first. Care should be taken to put in equal charges of composition each time, and to give to each ladleful the same number of blows and with the same force. Fuses are often driven by pressure in a screw-press.

Fuses are all driven to the same height by means of a mark on the short drift, or the composition is bored out with the gouge to the same depth. They are primed with mealed powder for about .2 inch, driven with the same force as a ladleful of composition. The cup is filled with a paste of mealed powder and spirits of wine or strong whiskey, and laid aside to dry; it is then covered with a small piece of paper, over which is pasted a cap of strong, water-proof paper, marked with the number of seconds the fuse burns to the inch.

Time-fuse for Guns.—This fuse consists of a *paper case* charged with fuse-composition; it is inserted, at the time of loading the gun, into a brass or wooden plug previously driven into the fuse hole of the shell. The following utensils are required for making the cases: *pattern* of wood, in the form of a rectangle joined to a trapezoid; *iron former*, .35 inch diameter; *knife; glue-pot; brushes*.

The paper is cut to the proper size by means of the pattern. The whole length of the strip must be determined by a trial for each kind of paper, to give the case the proper diameter. The strip is rolled hard on the former, beginning with the large end, and is glued after the first turn. When the case is dry, it is smoothed with a fine file or sand-paper.

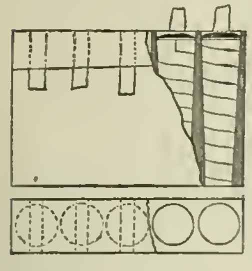
There are different compositions used, one inch burning 2.5, 5, 10, 15, and 20 seconds respectively. Their time of burning is subject to considerable variation, according to the quality of the ingredients and the manipulation in mixing them; the exact proportions must be determined by experiment. The composition is carefully mixed, and several fuses are first driven and their times of burning determined, and the proportions varied, if necessary, to produce the required result.

The following utensils are required for driving the fuses: *brass molds* in two parts, which are held together by a wedge or cam; the molds have holes for four or five fuses; *steel drifts*, .35 inch diameter; *knife; mallet*, weighing ½ pound.

The mold is put together and secured; the empty cases are inserted and driven gently in; their upper ends, projecting above the mold, are slit with a knife into four parts. The composition is put in and driven as described above, giving 15 blows to each ladleful, which will make .25 inch in length of the fuse. They are next primed by covering the larger ends with shellac varnish and dipping them into rifle-powder; when the priming has set, the entire fuse, except the priming, receives a coat of shellac varnish. The fuse is stained the proper color, according to the composition used, and the number of seconds that one inch will burn is marked on each fuse.

To cut the fuse it is inserted in an iron gauge, the bore of which is the same size and taper as the fuse, and its width is the true length of the fuse—2 inches. The projecting ends of the fuse are first sawed off with a fine saw and then trimmed with a knife. They are packed in wooden blocks (poplar), bored to receive five fuses each, and these blocks are wrapped in various-colored paper, to distinguish the different times of burning, having a printed label setting forth the kind of fuse, and place and date of manufacture, etc.

The fuses are applied to projectiles by inserting them in wood or metal plugs, which are driven or screwed into the fuse-hole of the projectile. For sea-coast service, the paper-case time-fuse is inserted in a metallic plug fitting the projectile. The metallic plug is fitted with a screw-cap, called a water-cap, having a crooked passage, through which, by suitable priming,



flame is communicated to the fuse, and the escaping gases are intended to exert sufficient pressure to prevent the entrance of water to extinguish the fuse, especially with spherical projectiles. The insertion of the fuse in the rear end of the rifle-projectile has been proposed to dispense with the use of the water-cap, but the enormous force exerted upon the projectile, while in the gun, has been a serious obstacle to the practical use of a rear fuse.

Fuses for Smooth-bore Field-guns and Mountain-howitzers.—A fuse for shells and spherical case-shot for field and mountain service is that known as the "Bormann fuse." It consists of a circular disk of soft metal, containing an annular space charged with mealed powder. The outer circumference of the disk is chased with the threads of a screw to secure it in the shell. The annular space for the composition is concentric with the outer circumference, and connects at one end by a hole with a small magazine in the center of the disk, filled with rifle-powder, and closed on the under surface by a thin disk of tin. The fuse is charged from the under side by pressure, and a ring of the same metal is pressed firmly on the composition. The composition is thus securely protected from accidents, and the fuse is screwed into the shell in the laboratory. The metal covering the composition on top, being left thin, is easily cut with a knife or cutter at the moment of loading, and the composition exposed at the required point to the action of the flame. The graduations into seconds and quarter-seconds are marked on the upper surface of the disk. The time of burning of the whole length of fuse is 5 seconds.

The following utensils are required for casting the fuse: *molds* for the fuse; *molds* for the ring; *hacksaw; nippers; mallet; kettle; ladle.*

Melt the lead and tin together; heat the molds so as not to chill the metal in casting. Fill the mold with the melted metal, and tap it gently with the mallet to make the metal fill the small parts. Cut off the gate with the saw, and the ends of the ring with the nippers. It has been found convenient in opening and closing the molds to attach the two parts of the mold for the fuse and also for the ring to the jaws of a bench-vise, so that both molds are opened and closed by the same movement of the screw. The fuse-mold is kept hot by means of iron disks, which are heated and hung on the arbor which supports the molds. A mold of more approved pattern has been devised by which the casting is expedited.

The following utensils are required for charging the fuse: a strong *screw-press; annular charger* the size of the ring; *annular drift; flat drift; round drift.*

Take the mold in which the fuse was cast, place the fuse in the parts of the mold containing the screw and the upper or graduated side, and secure the mold by a ring driven on it. Draw up the piston, and fill the charger by pressing it into the mealed powder contained in a shallow pan; place the charger over the groove and force down the piston, transferring the powder into the fuse; insert the button in the magazine and the pin in the priming-hole to preserve their shapes; place the ring on the powder, and, with the annular drift, force it down by means of a strong screw-press, bringing the ring flush with the surface of the fuse; rivet the ring in its place with another drift; withdraw the button and the pin, charge the priming-hole with rifle-powder, and fill the magazine with musket-powder; cover the magazine with a disk of tin, and rivet it in place by means of, first, a flat drift, and then a round one, which turns down a part of the metal of the fuse over the disk. Remove the fuse from the mold, place it in a screw-chuck made to fit it, and turn off in a lathe the lower surface smooth and to the proper thickness. The powder of the fuse is now perfectly sealed up from the air. The fuse should be varnished.

The following table shows the principal dimensions and weights of the service-fuses:

Dimensions and Weights.				Wooden Fuses.			Paper Fuses.
				13 inch.	10-inch.	8-inch.	
Fuse	Whole length		inches	10.8	9.4	6.3	2
	Diameter	At top	do.	1.85	1.7	1.25	.53
		At bottom	do.	1.25	1	.9	.4
		Of bore	do.	.4	.3	.3	.35
First cone	Length		do.	2.8	2 25	1.25	....
	Diameter at lower end		do.	1.65	1.55	1.15	....
Cup	Depth		do.	.6	.5	.4	....
	Diameter	At top	do.	1.25	1	.75	....
		At bottom	do.	.9	.8	.6	....
Thickness of wood at bottom of fuse			do.	1.2	.9	.9	....
Length of composition			do.	9	8	5	2
Drifts	Diameter		do.	36	.27	.27	.3
	Length, exclusive of handle	First	do.	9	8	8	....
		Second	do.	4.5	4	4	....
Weight	Of composition for 100 fuses		pounds	8	4	2.5	2
	Of 100 fuses complete		do.	54	33	16	....
Paper for the case	Whole length		inches	....	....	....	19
	Length of rectangle		do.	....	....	....	6
	Width of rectangle		do.	....	....	....	2.25

Bormann Fuse.

Diameter of fuse, including threads	1.65 inch.
Thickness	.45 incb.
Number of threads to the inch	12
Diameter of plug, including threads	1.07 inch.
Thickness for field-guns	.3 inch.
Number of threads to the inch	12

PERCUSSION-FUSES.—Many varieties of fuses have been used in service, under the names of percussion and concussion fuses. Among the simpler ones, the Absterdam, Hotchkiss, Parrott, and Schenkl may be named. They are much alike in their general features. They consist of hollow metallic screw-plugs to fit the fuse-hole of the projectiles. A loosely fitting plunger is inserted in the bore of the plug, the front end of which is closed by a screw-plug or cap. On the forward end of the plunger a percussion-cap, or rather detonating device, is arranged, to be exploded and communicate fire to the bursting-charge, through an opening at the rear, by the plunger striking the plug or cap when the motion of the projectile is arrested. Various safety devices are used, having sufficient strength to prevent the plunger being thrown forward by shocks in transportation, etc., but weak enough to be broken by the shock of discharge, or impact of the projectile, as the case may be.

COMBINATION FUSES.—Many varieties of combination-fuses have been proposed and tested, but without satisfactory results. This variety of fuse would be best adapted to general service if perfected. If a perfect combination-fuse can be made, none other would be required, as it would have the properties of the other two, capable of use separately or combined. Granting certainty of ignition of the time element, only one kind of fuse would be required for all kinds of service. A good one should possess, in one structure, the properties of the most perfect time- and impact-fuses. It should be simple in construction, safe to handle and transport, and easily applied to the projectile.

It is the opinion of many who have given the subject much study that no fulminate or friction composition should enter into its construction, except perhaps to insure the ignition of the time element of the combination. Certainty of ignition by the gases in the gun is not always attainable, especially with rifle-projectiles and breech-loading cannon which have but slight windage; therefore some form of inertia igniter is necessary. Such igniters are simple and easily made, and may be arranged for attachment to the fuse at the last moment before loading the gun, thereby avoiding all risk of accident in transportation, etc. The above conditions exclude all but a few of the devices subjected to trial, and the subject is still unsettled and under test. No one variety of the many offered for test has given sufficiently satisfactory results to warrant its adoption.

It is impossible that any species of fuse should be absolutely perfect. When suitable opportunities for observation occur, it is noticed that in firing a number of shells many do not explode. The failure of the composition to ignite is probably generally due to the absorption of moisture; and therefore all fuses which have been more than one year in service should be returned to the laboratory. Fuses of over two years' date of manufacture should not be issued for service. Sometimes the fuse is extinguished after having been ignited. This may occur when the shell ricochets on soil or water. Water is not so detrimental as sand, and the fuse is rarely extinguished by several ricochets upon it. Generally the gases evolved by the combustion of the composition will repel with great energy any obtrusive matter which would extinguish the fuse if once in contact with the ignited surface.

Premature explosions may be caused by the increase of the ignited surface of the composition resulting from cracks in the case or composition itself, or by interstices between the case and composition; and in proportion to the extent of this cause so will be the increased celerity of the combustion. Crevices may occur in the composition from some defect in the tools or in the mode of using them, or they may be created by bending the case. It may also happen that the displacement of the shell by the charge of the gun will force in the column of composition or the case with it. This would of course cause the shell to explode very quickly. The shell may be defective in thickness or quality of metal, and be crushed by the force of the discharge, when the explosion will take place in or near the gun. The bursting of the shell near the muzzle of the gun is sometimes attributed to the detonating qualities of the powder in the shell. It is manifest that the premature explosion of shells is far more detrimental to their efficiency than the failure to be exploded at all. See *Abstrdam Percussion-fuse, Bormann Fuse, Boxer Fuse, Concussion-fuse, Detonating-fuse, Dynamo-electric Igniter, Eggo Percussion-fuse, Electric Fuses, Fire-works, German Percussion-fuse, German Time-fuse, Gill Combination-fuses, Hotchkiss Percussion-fuse, Lissberger Fuses, McIntire Fuses, Mortar-fuse, O'Reilly Combination-fuse, Percussion-fuse, Pettman Fuse, Plumacher Percussion-fuse, Royal Laboratory-fuse, Ruben and Fornerod Combination fuses, Running-fuse, Schenkl Percussion-fuse, Seacoast-fuse, Splingard Fuse, Thompson Combination-fuse, Time-fuse, Treadwell Combination-fuse*, and *Ware Combination-fuses.*

FUSE-AUGER.—An instrument for regulating the time of burning of a fuse by removing a certain portion of the composition. It consists of a steel bit, fastened into a wooden handle, at the lower end of which is a brass socket, with a bar, under which a graduated limb of the slider moves. The bit fits into the slider, and is by a steel thumb-screw fastened to it in any required position. The position of the slider, which determines the depth to which the auger bores, is regulated by a fine scale attached to it by a screw.

FUSE BLOCK.—A simple contrivance for holding paper time-fuses when being cut. It consists of two blocks of wood hinged together so as to open and shut after the manner of a book. In each end is a recess into which the fuse is placed, and where it is securely held by pressing the blocks tightly together. The fuse is put in with the small end extending out of the end of the block, the point at which it is to be cut being even with the end of the block.

Along one side of the recess is attached the brass scale. This was intended for fuses of obsolete pattern. As now made, each fuse is divided into as many equal parts as the number of seconds for which its entire length (two inches) is intended to burn. These parts are marked, and are the guides in cutting the fuse; the latter operation being performed with the *fuse-knife*, which is a very sharp and thin-bladed knife (preferably a shoe-knife), or a fine saw.

FUSE-ENGINE.—A name formerly given to an instrument for extracting a wood fuse when fixed in a spherical shell. As it was found faulty in construction it has been replaced by the present fuse-extractor, which is applicable to extracting wood fuses from rifled shells.

FUSE-EXTRACTOR.—An implement used for extracting wooden fuses from the fuse-hole, when they have been too firmly driven to be withdrawn by the *shell plug-screw*, or in any other way. It consists of an inner screw and stem of steel, riveted to an iron handle, and contained in a hollow steel screw, which works up and down by means of an iron nut with two handles. The hollow screw is prevented from turning by a slot and a feather in the frame, which is of brass. The nut is kept in place by four iron set-screws, the points of which enter into a groove in the nut. To extract a fuse, the bottom of the frame is placed on the shell over the fuse-head, and the inner screw screwed into the fuse by means of the upper handle. The handles of the nut are then turned, which raises the hollow screw, and with it the inner screw and the fuse.

FUSE HOLE.—The hole in a shell prepared for the reception of the fuse-stock. The loss of force by the fuse-hole may be ascertained with sufficient accuracy, provided we know from an actual experiment the amount of the loss from the fuse-hole of any one shell.

Let R and r be the exterior and interior radii of a spherical projectile; T, the tenacity of the metal; i, the radius of the fuse-hole; w', the weight of powder necessary to burst it under the supposition that there is no loss of force at the fuse-hole; w, the weight of powder that is actually required to burst it. By formulas approved we obtain the value of w'; $w - w'$ is therefore the amount of loss from the fuse-hole. Take another projectile, and let w_1' represent the charge which is necessary to burst it, under the supposition that there is no loss, and w_1 the weight that is found by experiment necessary to burst it; $w - w_1'$ will represent the loss. We are at liberty to suppose the loss from the two fuse-holes is proportional to the size of the holes, and the density of the gases at the moment of rupture; we shall therefore have this proportion:

$$w - w' : w_{,} - w_{,}' :: i^2 d : i_{,}^2 d_{,}.$$

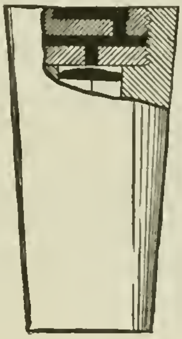
Or,

$$w = w' + (w_{,} - w_{,}')\frac{i^2 d}{i_{,}^2 d_{,}}.$$

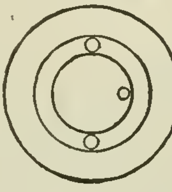
From the experiments made at Metz in 1835, it was shown that this mode of estimating the loss of force by the fuse-hole was sufficiently accurate for practical purposes. See *Bouching* and *Shells*.

FUSE-MALLET. — An implement for setting the fuse home. It is cylindrical in shape, with a handle on one end, and is turned out of a single piece of dog-wood, oak, or other hard wood.

FUSE-PLUG.—Fuse-plugs are made of brass or of close-grained wood, well seasoned. They are turned to a size a little larger than the fuse-hole, but of the same taper,—2.5 inches long; a hole is bored through the axis and reamed out to receive the paper fuse, and the large end is counterbored and tapped to receive the water-cap. If a wooden plug be used, a short, hollow cylinder of brass, .5 inch long, .15 inch thick, is inserted in the recess before the plug is driven, and afterwards tapped to receive the water-cap.



The *water-cap*, shown in the drawing, is a plug of brass, .5 inch long, .6 inch in diameter, chased with 12 threads to the inch. One end has a shallow recess cut in it, .1 inch deep, larger at bottom than at top; a hole .1 inch in diameter is bored through the middle of the cap, and a hole is bored from either end into this transverse hole, but meeting it at points .25 inch or more apart; these and the recess in the end are filled with mealed-powder paste. Diameter of hole at bottom of recess, .53 inch; at small end, .4 inch.



A little shellac is brushed around the safety-plug and lower end of fuse-plug; also around the leaden patch and top of stock. A pasteboard cap is put on over the safety-plug end of the fuse-plug to prevent the plug from being broken off, and the fuses thus prepared are stowed in boxes. See *Fuse* and *Water-cap*.

FUSE-REAMER.—The implement used to enlarge the hole in a fuse-plug so as to make it of the proper size for the paper fuse.

FUSE-SETTER.—An implement for setting wooden fuses in the fuse-hole. It is made of brass; the bottom is countersunk and cup-shaped, to prevent it from slipping off from the head of the fuse.

FUSE-WRENCH. — A three-pronged wrench used for setting fuse-plugs that are to be screwed into the shell. One prong contains forks for the fuse-plug, and another one smaller forks for the water-cap.

FUSIBLE METAL.—Fusible metal is composed of 2 parts of bismuth, 1 of lead, and 1 of tin. It fuses at 201° F., becoming pasty before it completely melts. It expands in a very anomalous manner; its bulk increases regularly from 32° to 95°; it then contracts gradually to 131°; it then expands rapidly till it reaches 176°, and from that point till it melts its expansion is uniform. The faculty of expanding as it cools, while still in a comparatively soft state, renders the alloy very serviceable to the die-sinker, who employs it to test the accuracy of his die, every line being faithfully produced in the cast made of the alloy. The proportions of the three metals are sometimes varied, and another formula is given in the table in FUSING AND FREEZING POINTS.

FUSIL.—1. A firelock lighter than the musket, invented in France about 1635, and deriving its name from the Italian word *focile*, "a flint." In 1678 a British regiment was armed with the fusil, and the King added a company of men armed with hand-grenades to each of the old British regiments, which was designated the Grenadier Company.

2. *Fusil* is represented heraldically as longer and more acute than a lozenge.

FUSIL A CHEVALETS.—A species of fusils upon rests, which was recommended by Marshal Vauban to be used at the commencement of a siege, about 50 or 100 toises in front of the glacis, at the entrances of narrow passages, etc.

FUSILIER.—Formerly a soldier armed with a shorter and lighter musket than the rest of the army, which he could sling over his shoulder. The fusilier regiments, of which there are ten in the British service, are not distinguished from the Infantry of the Line as they formerly were; the title is now purely honorary, and they are armed and dressed in every way like the line regiments, except in the head-dress and the mode of wearing their chevrons. The head-dress of the officers is a busby, the material of which is made of raccoon-skin, for that of the non-commissioned officers and of the men, of seal-skin. On parade, or marching in quick time, or upon occasions of guard-mounting parade, or review, they always march to the Grenadiers' March.

FUSILLADE.—The simultaneous discharge of firearms in various military exercises.

FUSIL-MOUSQUET.—A name applied to the *flint-lock* gun, invented about 1640, and introduced into the French army by Vauban. This gun had a bayonet with a socket.

FUSIL-RAYE.—The name given to the early long-range rifle of the Imperial Guard.

FUSILS A L'EPPE.—Fusils with long bayonets, shaped like a cut-and-thrust sword. These weapons were recommended as extremely useful in the rear rank of a battalion, or in detached bodies that are stationed for the defense of baggage, etc.

FUSING AND FREEZING POINTS. — Terms applied to the temperature at which solids assume the liquid form and liquids become solid. The following table gives some of the best determinations of the fusing-point:

Mercury	−39°
Oil of vitriol	−30°
Bromine	9°.5
Oil of turpentine	14°
Ice	32°
Lard	91°
Phosphorus	111°.5
Potassium	136°
Yellow wax	143°.6
Stearic acid	158°
Sodium	207°.7
Fusible metal (5Pb,3Sn,8Bi)	212°
Iodine	226°.4
Sulphur	239°
Alloy (1Sn,2Bi)	286°
" (3Sn,2Pb)	333°
Tin	451°
Bismuth	512°
Nitrate of soda	591°
Lead	620°
Nitrate of potash	642°
Zinc	773°
Antimony (about)	900°
Silver	1773°
Copper	1996°
Gold	2016°
Cast-iron	2786°
Wrought-iron, higher than	3280°

We see from this table that alloys may have a fusing-point far below that of any of the metals which enter into their composition. Similarly, mixtures of various silicates fuse at a temperature far below that which is required to melt any one of them, and the same remark applies to mixtures of various chlorides, carbonates, etc.

Most solids, when heated to their fusing-points, change at once into perfect liquids; but some—as, for example, platinum, iron, glass, phosphoric acid, the resins, and many others—pass through an intermediate pasty condition before they attain perfect fluidity, and, in these cases, it is difficult, if not impossible, to determine the exact fusing-point. This intermediate condition is termed *vitreous fusion*, because it is a characteristic property of glass. It is in this intermediate state that glass is worked, and iron and platinum forged.

As a general rule, the freezing-point is the same as the fusing-point—that is to say, if a substance in the liquid form be cooled below the fusing-point, it again becomes solid; but there are cases in which we can cool a liquid several degrees below its fusing-point; thus, by keeping water perfectly still, we can cool it to 5°, or even to 1°.4, before it freezes. If, however, we drop a solid body into water in this condition, or if we shake the vessel containing it, congelation begins at once, and the temperature rises to 32°. This phenomenon is exhibited to a still greater degree in viscid fluids, like the oils. It is well known that the freezing-point of water is depressed by the presence of salts. Thus, sea-water freezes at about 26°.6, and a saturated solution of common salt must be cooled as low as 4° before freezing.

FUSS-STREITAXT.—A German battle-axe, having a long handle and used by the foot-soldiers.

FUST — FUSTAGE. — The very early gun-carriage, upon which the ancient bombard was fixed by means of iron work. These carriages consisted of blocks of wood or frame structures, made in imitation of the mountings of small-arms.

FUSTIBALE.—A kind of sling with a handle fastened to it. It was used as late as the sixteenth century for hurling fireballs and grenades.

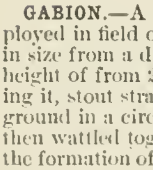
FUSTUARIUM.—In Roman antiquity, a method of inflicting capital punishment upon any soldier guilty of theft, desertion, or similar crimes. When the accused had been found guilty, he was made to stand in front of the legion to which he belonged. One of the Tribunes then touched him lightly with a stick, and all the soldiers immediately rushed upon the criminal and beat him to death with clubs (fustes). If he escaped—as he was allowed to do if he could, but which was rarely if ever possible—he was forbidden ever to return to his native country, and his nearest relatives were not allowed to receive him into their homes or houses. This method of capital punishment continued to be enforced even under the Empire.

FUTCHELLS.—Horizontal longitudinal bars which rigidly connect the splinter-bar with the axletree-bed, or with springs or other intermediate connection between them and the axletree.

FYROZ.—A Persian word signifying *victorious*, and forming the name of several ruling kings in Persia and Hindostan. Also written *Feroze.*

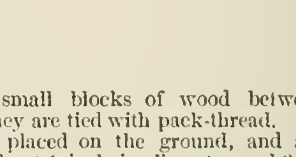
G

GABION.—A hollow cylinder of basket-work, employed in field or temporary fortification, and varying in size from a diameter of 20 inches to 6 feet, with a height of from 2 feet 9 inches to 6 feet. In constructing it, stout straight stakes are placed upright in the ground in a circle of the required diameter, and are then wattled together with osiers or green twigs, as in the formation of baskets. The apparatus being raised, when completed, from the ground, the ends are fastened, and the gabion is ready to be rolled to any place where it is desirable to form the breastwork against the enemy. Placed on end, and filled with earth, a single row of gabions is proof, except at the points of junction, against musketry-fire, and by increasing the number of rows any degree of security can be obtained. The gabion has the advantage of being highly portable, from its shape, while with its aid a parapet can be formed with far less earth, and therefore in less time, than in cases when allowance has to be made for the slopes on both sides, which are necessarily present in ordinary earthen walls. The *sap-roller* consists of two concentric gabions, one 4 feet, the other 2 feet 8 inches, in diameter, with the space between them wedged full of pickets of hard wood. In sapping, these serve as substitutes for mantlets. *Stuffed gabions* are gabions rammed full of broken branches and small wood; being light in weight, they are rolled before soldiers in the trenches, and afford some, though not a very efficient, protection against musketry-fire.



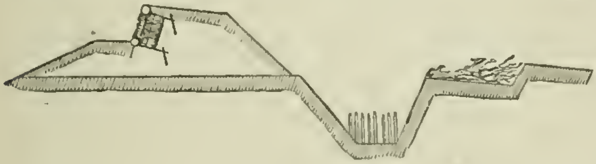
To form a gabion, a *directing circle* is made of two hoops, the difference between their radii being such that, when placed concentrically, there shall be about 1¾ inches between them. They are kept in this position by placing small blocks of wood between them, to which they are tied with pack-thread. The directing circle is placed on the ground, and seven or nine stakes, about 1 inch in diameter and 3 feet long, are driven slightly into the ground between the hoops, at equal distances apart; the directing circle is then slipped up midway from the bottom, and tied in that position. Twigs about half an inch in diameter, and as long as they can be procured, are wattled between the stakes like ordinary basket-work: when finished within about 1½ inches of the top, the gabion is placed with the other end up, the directing circle is taken off, and the gabion is completed within the same distance from the other extremities of the pickets. The wicker-work at the two ends is secured by several withes, and the ends of the pickets being brought to a point, the gabion is ready for use. See *Gabion Revetment, Jones Gabion,* and *Tyler Gabion.*

GABIONADE.—Traverses placed between guns or on their flanks to cover them from an enfilade-fire are usually termed *gabionades*. To form a gabionade, gabions are placed in a row, side by side, inclosing a



rectangular space of about 15 feet in width from out to out, and about 24 feet in length, perpendicular to the parapet. A second row is placed within this and touching it, and a third row inside of the second. The area thus inclosed is filled in with earth to a level with the top of the gabions. Six rows of large fascines are next laid on the gabions to support a second tier consisting of two rows. The second tier is filled in like the first, and the earth is heaped up on top. Four rows of large fascines are placed on these to support a third consisting of one row, making the gabionade nearly twelve feet high. The ends are inclosed by filling in with gabions, as for the sides. A passage-way of about two feet is left between the end of the traverse and the parapet. This space may be roofed over with logs and earth to form a cover in which the cannoneers may shelter themselves against fragments of shells. *Splinter-proof traverses* may be made by placing two thicknesses of gabions side by side filled with earth, with a second tier of one thickness on top. When a service-magazine is to be placed in a gabionade, the rows of gabions are set farther apart, and the excavation for the magazine is made between them. The chamber of the magazine is constructed in one of the ways heretofore described. A *parapet en gabionnade* is a parapet constructed of gabions. See *Traverse*.

GABION REVETMENT. — Gabion revetments are rarely used for the interior slopes of ordinary field-works. They are much and usefully employed in the trenches in siege-operations, in batteries, and in embrasures. When used as a revetment for the interior slope, they give a height of three feet, in consequence of the projecting ends of the pickets. They are made to rest upon a row of fascines half buried in the banquette, and are so placed as to have the same inclination as the interior slope. The gabions are then filled with earth, and the parapet is raised behind them. When the parapet reaches the height of the gabion, a row of fascines is laid on top of the gabions to give the requisite height to the interior crest.



Profile of Gabion and Fascine Work.

To form this revetment, a fascine is first laid partly embedded below the tread of the banquette; the gabion, which is placed on end, rests on this, so as to give it the requisite slope; it is then filled with earth; others are placed in like manner, and the parapet is raised behind them; another fascine is laid on top, and in some cases two. The drawing shows the profile of gabion and fascine work, with small pickets in the ditch, and an abatis behind the glacis. In making the gabions, iron hoops, similar to barrel-hoops, may be used instead of wattling. The number of stakes should be increased to eleven or thirteen. Gabions made either of wattlings or hoops are not good for holding dry sand. Sheet-iron is preferable to either iron hoops or brush for gabions. For this purpose rectangular sheets of suitable dimensions to form cylinders of the same height and diameter as the ordinary gabion are prepared, with three holes punched near to and parallel with the shorter sides of the sheets. These are to secure the ends with wire when the sheet is bent into the cylindrical form. The advantages of this description of gabion are greater strength, lightness, and durability than either of the other two, offering great facility for transportation, and resisting better the blast of guns when used for revetting the cheeks of embrasures. Galvanized iron is less liable to rust than plain iron; when not galvanized, the gabions should be always lacquered with coal-tar. See *Revetment*.

GABION TRIP.—The bands of Jones's iron gabions may be formed into a network as an obstacle against cavalry and even against infantry in night-attacks. The bands are buttoned and placed in line 3 or 4 feet apart; each band is then connected with the next by stout wire or rope passed through binding-holes. Bands thus connected should be laid in parallel rows, checkerwise, 3 or 4 feet apart, the rows also connected by wire or rope and secured at intervals to pickets driven into the ground. See *Gabion*.

GAD—GADLING.—An old Norman name given to that part of the gauntlet which covers the knuckle, and which was armed with knobs or spikes of iron. In a trial by combat adjudged between John de Visconti and Sir Thomas de la Marche, fought before Edward III. in close lists, at Westminster, Sir Thomas de la Marche gained the advantage by striking the gadlings of his gauntlet into the face of his adversary. The term *gad* is also applied to the point of a spear or an arrow-head, and the withe used in the construction of fascines.

GADARU.—The French term employed for a very broad Turkish saber, formerly in common use.

GAFFLES.—A name applied to the steel levers by means of which the ancients bent their cross-bows.

GAGE.—1. A pawn or pledge. The word is derived from the French *gager*. Hence, by changing *g* into *w*, we have *wage* and *wager;* as, "wager of law," "wager of battle," wherein a person gave his pledge that he would sustain his affirmation; and, in the latter case, the glove was sent as a material pledge to be redeemed by a mortal combat. Hence also in England.

2. A tool for setting out lines and grooves parallel with the margin of the carpenter's work. The "stem" of the gage is retained in the head or stock by means of a small wedge, and the cutter is fixed in a hole at right angles to the face of the stem by another wedge. There are several forms of gages, such as the *marking, cutting, router, mortise gage*, etc. See *Gauge*.

GAINE DE FLAMME.—A variety of linen sheath or cover into which the staff of a flag or pendant is put.

GAINE DE PAVILLON.—A cloth or linen band which is sewed across the flag, and through which the different ribbons are interlaced.

GAINING TWIST.—Some of the rifles and rifled ordnance in the service are made with grooves which have a very slight twist at the breech, but the twist is increased regularly until it reaches the muzzle; this is known as the *increasing* or *gaining twist*. At the instant of discharge, when the shot from a state of rest is instantly given a high velocity, it would seem likely to be pushed across the grooves, especially if they have a great inclination. To avoid this, the inclination of the grooves is made slight at the breech, and increased gradually toward the muzzle, at which point they are sufficiently inclined to give the necessary rotatory motion. In the increasing twist, though the projectile leaves the seat or chamber of the gun with great velocity, and relieves the breech a good deal from the strain of the discharge, its velocity is less than from a gun with *uniform twist*. See *Twist*.

GAIN-PAIN.—A term applied in the Middle Ages to the sword of a hired soldier.

GAITERS.—A sort of cover for the leg, usually made of cloth, and either long or short. Those reaching just above the ankle are termed *half-gaiters*, and are worn by infantry soldiers in Europe.

GALEA.—Among the Romans, a light casque, head-piece, or morion, coming down to the shoulders, and commonly of brass; though Camillus, according to Plutarch, ordered those of his army to be of iron, as being the stronger metal.

GALENA.—A mineral which is essentially a sulphuret of lead, the proportions being 13.3 sulphur and 86.7 lead; but usually containing a little silver, and sometimes copper, zinc, antimony, or selenium. It is of a lead-gray color, with a metallic luster, is found massive, or sometimes granular, or crystallized in cubes or octahedrons. It is very easily broken, and its fragments are cubical. It occurs in veins, beds, and embedded masses, often accompanying other metallic ores, in primitive and secondary rocks, but most of all in what is known as transition or mountain limestone. It is found very abundantly in some parts of Britain. Almost all the lead of commerce is obtained from it. It sometimes contains so much silver that the separation of that metal is profitably carried on. The lead is extracted from it by a very simple process. See *Lead*.

GALE'S COMPOUND.—Powdered glass with gunpowder, rendering the latter non-explosive; so named after the patentee.

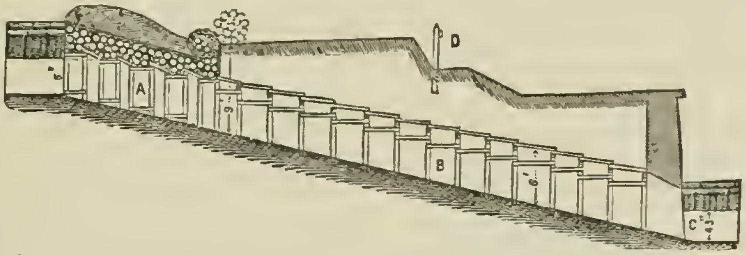
GALET.—The French name for the German *ballestre*, a cross-bow above the ordinary size. The term is also applied to a round stone thrown from a sling or bow, and is sometimes written *Gallet* and *Jalet*.

GALL.—The wound inflicted on draught or riding horses from the imperfect fitting of the harness or saddle. The slightest tendency to gall should be promptly looked after. Hot water and poultices make the best early treatment. Leather burned to a crisp and finely powdered, when spread over the wound, causes it to heal very quickly. There is no excuse for the frightful wounds on the backs of mules and horses due to improper saddling.

GALLAS.—A warlike race occupying the South and East of Abyssinia. The general name by which the tribes designate themselves is *Oroma* (*orma*, men). Although generally belonging to the negro race, they are not purely negroes, but form with the Fulahs, Mandingoes, and Nubas, as it were, the transition to the Semitic variety, and seem to belong to that great family inhabiting the East of Africa, from the frontiers of the Cape land to Abyssinia, and usually denominated the Kaffers. They are a vigorous, well-formed people of a dark brown color, with hair frizzled but not quite woolly, round faces, and small sharp eyes, and are distinguished not less by their energy and warlike spirit than by their mental capacities. They first appear in history in the sixteenth century, as a barbarous people, extending their conquests from the interior of Africa, laying waste, by constant incursions, the countries of Eastern Africa, to the mountains of Abyssinia, gradually subduing or expelling the original inhabitants (hence their name), occupying great part of Abyssinia, and advancing as far as the Red Sea and the Gulf of Aden. It is only of late years that their power in Abyssinia, and their incursions into that country, have been partially checked, chiefly by the vigorous government of the King of Shoa, who subdued some of the Gallas tribes and induced them to profess such Christianity as exists in Abyssinia. They still, however, occupy many districts of Abyssinia, and extend their power to an indefinite extent over the countries situated south and southwest of it. Politically, the Gallas do not form a single Nation, but are divided into numerous tribes, forming separate Kingdoms and States, which are frequently at war with each other. Most of the Gallas follow pastoral avocations. Some, however, through intercourse with the semi-Christian, semi-civilized Abyssinians, have become tillers of the soil. The wandering Gallas are mainly engaged in hunting and the slave-trade. The larger number of the Gallas are still heathens, though Mohammedanism has lately made great progress among them. Their religion bears a resemblance to that of the Kaffers.

GALLERY.—A covered passage cut through the earth or masonry in a fortification, either as a means of communication, or as a position whence a musketry-fire can be maintained through loopholes. For the latter purpose, galleries are formed occasionally in the counterscarps of dry ditches, where their defenders exercise a flanking fire upon the ditch. To explain the practical operations in driving a gallery, let an example be taken where the soil is loose, and the floor of the gallery rises from the point of departure. In this case the first frame of the gallery must be set up within the shaft and against the shaft-frames, on the side from which the gallery is to open. The ground-sill of this frame being laid, the stanchions are secured to the intermediate shaft-frames of the last interval by battens, and the top sill fastened. A horizontal beam is then secured to the under side of the top shaft-frame of the same interval, to preserve the proper slope for the top sheeting when inserted; wedges being placed between this beam and the sheeting-board for this purpose. A like arrangement for the side sheeting may be made if necessary. The excavation of the gallery is now commenced at top, by forcing down with a crowbar the sheeting of the shaft on the side of the gallery. The earth is removed gradually forwards and downwards, and the gallery-sheeting advanced at the same rate. When the excavation has reached as low as the intermediate shaft-frame, the piece of it that sustains the lower portion of the sheeting is removed to allow the excavation to proceed. When in this way the earth is removed as far as the middle of the first interval, the auxiliary gallery-frame is set up, to support the top and side sheeting until the second gallery-frame is placed. To place this last frame, the position of the ground-sill is first determined by placing the slope-block on the ground-sill first laid, and then, by a common mason's level upon the side of which the interval is marked, laid upon the slope-block, bringing the top of the ground-sill on the same level as that of the slope-block. The sill being adjusted and firmly secured, the stanchions are next set up, and secured by battens to the stanchions of the first frame, and the cap-sill is secured in the last place. The adjustments of the stanchions and cap-sills are made by an ordinary plumb line, by means of which the edges of the stanchions are placed vertically, and the scores on the cap- and ground-sills brought into the vertical plane of the axis of the gallery. The battens are placed horizontally. In a level gallery they are nailed alternately at 4 and 8 inches below the cap-sill. In others they are nailed 4 inches below the lower of the cap-sills of the two frames which they unite; this will bring them to 4 inches, added to the height of the slope-block, below the other. The auxiliary frame is not taken down until wedges have been placed between the sheeting and the frame last placed, in order to introduce the boards for the next interval; and these last are kept in the proper direction, as the excavation is advanced, by wedges inserted between them and the sheeting of the interval finished. See *Auxiliary Frame*, *Branch Galleries with Dutch Cases*, *Gallery Descent*, *Gallery Intervals*, *Scarp-gallery Shaft*, *Slope-block*, and *Wooden Gallery*.

GALLERY DESCENT.—A descent to a ditch is usually by blindage when the depth of the ditch does not exceed 10 or 12 feet. For greater depths the commencement of the descent is by a blindage which is continued to a point where the bottom of the descent is about 9 feet below the surface of the ground; here the blindage is terminated, and the remainder of the descent is made by gallery, as the depth of the earth above the gallery will be sufficient to allow the excavation to be carried on without trouble. In a firm soil, grand gallery-frames are used for the descent; in a loose soil, common gallery-frames. The frames used and construction of the gallery are the same as for a mine-gallery. The point of departure of a ditch descent is usually taken at only about 2 feet below the bottom of the trench; the usual landing being made at this point. In a dry ditch, the bottom of the descent should come out at the usual depth of the full sap below the bottom of the ditch. In a wet ditch it should come out about 15 inches above the water-level. The passage of a dry ditch is nothing more than a full sap, which leads from the outlet of the descent in the ditch to the bottom of the breach. From this point the trench and parapet are directed up the breach to the scarp-wall, which forms the side of the breach towards the dangerous point. The only precaution necessary in making this passage is to sink the trench at the outset to its full depth of 43 inches to gain secure cover. The passage of a wet ditch is a perilous and difficult operation under any circumstances, but particularly so when a strong current can be produced, by the besieged, in the ditch. The methods usually recommended are to form a dike, or bridge of fascines and hurdles, laid in successive layers, and firmly connected by pickets. To form a footing for the dike, a grand gallery is excavated, directly behind the counterscarp-wall, to a distance of 12 or 15 feet on each side of the descent, and the earth from it is thrown into the ditch, through the outlet of the descent. The dike or bridge of fascines is gradually pushed forward from this point, being secured in the best way practicable to the earth thrown into the ditch. The sappers who carry forward the head of the dike are covered from the fire of the dangerous point by a musket-proof mask of fascines and boards, attached to a raft on which they work. The dike should be from 12 to 15 feet wide at top. A gabionade parapet, formed of two tiers of gabions filled with earth, is placed on it towards the dangerous side. The bottom tier consists of two rows of gabions, each crowned with two fascines, the two rows being in juxtaposition; the top tier is a single row crowned with three fascines. The top of the dike is covered by a layer of earth, and the parapet with raw hides, to prevent the effects of incendiary compositions that might be thrown on them. Raft-bridges, on barrels, protected by a gabionade parapet, have also been proposed, particularly where a strong current is to be contended with. See *Gallery*.



Longitudinal Section of Blinded and Gallery Descent into Ditch. A, Blindage-frames; B, Gallery; C, Passage of Ditch; D, Covered-way.

GALLERY INTERVALS.—The portion of the floor of the gallery between the frames that bound the entrance to a return is termed a *landing*. The landing is in all cases horizontal, as well as that portion of an oblique return between the oblique frame and the one next succeeding, which last should not be placed farther than an ordinary interval from the farthest point of the oblique frame.

Having determined, by means of the working sketch, the landings and their frames, with respect to the points of intersection of the axis of the gallery of departure with those of the returns, the intervals of this gallery can be calculated, and their positions marked out on the sketch. The manner of making this estimate will be best illustrated by observing the following example:

Let A B = 118 feet be the total length of a gallery of departure, estimated horizontally along its axis, from the central picket of the shaft from which the gallery starts. At the point C, 44 feet from A, the axis of a rectangular return commences; and at D, 44 feet farther, that of an oblique one. The part A C of the gallery is to be a common great gallery, the part C D a common gallery, and the portion D B a great branch. With these data it is required to determine the intervals for the different portions of the gallery.

To find the interval for the first portion, A C, subtract from the total distance, 44 feet, the following aggregate:

Half the width of the shaft in the clear. ..	2 ft. 2 in.
The thickness of the lowest shaft-frame...	4½ "
Half the width of the landing at C.......	2 " ½ "
Thickness of a gallery-frame at the landing	5 "
	5 ft.

Which leaves 39 feet to be divided into suitable intervals; which may be done by constructing twelve of them each 3 feet 3 inches.

The intervals of the portion C D will be found as follows. From 44 feet take the following sum:

Half the width of the landing at C......	2 ft. ½ in.
Thickness of the landing-frame.........	5 "
The distance from D (as found from sketch) to the landing-frame back.....	9 "
Thickness of gallery-frame at landing D.	4½ "
	3 ft. 7 in.

Which leaves 40 feet 5 inches. This can be divided into nine intervals, each 3 feet 1 inch, and four of 3 feet 2 inches each.

To find the intervals for the part D B, from 30 feet take the following aggregate:

Distance from D to frame of landing beyond it..................................	4 ft. 5 in.
Thickness of landing-frame beyond D....	3½ "
Thickness of last frame at B.......	3½ "
	5 ft.

This leaves 25 feet, which can be divided into six intervals of 3 feet 2 inches each, and two of 3 feet. See *Gallery*.

GALLERY TARGET-PRACTICE.—The method of using round balls and reduced charges in the service cartridge-shells solves practically and satisfactorily in many respects the question of unlimited target-practice. For this practice the targets are reduced directly as the ranges. The balls should be of sufficient diameter to slug in the rifling of the bore, and fit closely over the powder in the bottom of the shell. Any motion of the ball in the shell would vary the position the powder takes when poured in, and gives uncertain shooting. There is less fouling of the gun-barrel when the balls are slightly lubricated with Japan wax, paraffine, or some lubricant that solidifies in cooling, as distinguished from oils that remain liquid. Good results have been obtained by melting Japan wax, immersing the balls in it, and shaking off the excess of the lubricant in a sieve. In firing 100 rounds with ball lubricated, the weight of fouling was 50 grains, without lubricant 150 grains. When no lubricant is at hand, wiping out the bore after every 5 or 10 rounds, and then running a slightly oiled rag through it, will answer. The firing is more accurate when the shells and gun are cleaned after every 5 or 10 rounds; the shells washed in warm water, and the bore of the gun wiped out by pushing a wet rag through it, and afterwards an oiled one. The endurance of the Frankford, Lowell, and Winchester shells is from 200 to 300 rounds fired with round balls and small charges. They give out by the bottom of the pockets getting knocked in by repeated blows of firing-pin, which causes the primers to miss fire. When short of shells, the expedient could be resorted to of putting a thin disk of metal in the bottom of the pocket, with a vent hole in the middle, until the bottom of the pocket is entirely knocked through. Charges of 3, 4, and 5 grains of Oriental standard musket-powder give good accuracy at 50, 75, and 100 feet respectively, firing from a shoulder- and muzzle-rest. A wooden drift, with shoulder to prevent the ball from being driven in too tightly, is convenient. When any shell becomes expanded so as to fit the chamber of the gun tightly, it can be re-sized in the resizing die accompanying the reloading tools. This will not often happen. The penetration of round ball with 5 grains powder at 50 feet is about 1 inch in white pine, and slightly more in hemlock. A board from 2 to 4 inches thick is soon cut through by the balls. A box or barrel filled with dirt and placed in rear of target will catch the spent lead and prevent injury to the gallery. A butt made larger and filled with earth or sand will afford a better protection. If the balls are fired into and lodged in thick wood, difficulty will be experienced in digging them out. An iron screen would cause the balls to splash and rebound about the target; hence earth would seem to be best to fire into. The above gives some idea as to what should be done to prevent the gallery from being defaced and persons being injured standing near the target for scoring shots. A pound of powder furnishes 1400 five-grain charges, a pound of lead 50 balls. The lead can be recast as long as it lasts, taking care that it is not burned in remelting. Fifty shells will answer for 10,000 rounds at 200 rounds each, requiring 10,000 primers for reloading. With 50 men to a company, 10,000 primers, 50 shells, 40 pounds of lead, and 7 pounds of powder will give 200 rounds per man, assuming that the balls can be remelted and recast four times before the lead is entirely consumed. Friction in shooting wears away the lead. It appears evident that by the use of the round ball with reduced charges in the service-rifle the recruit may more readily than otherwise be taught to hold his gun with steadiness, pull trigger without deranging his aim, and overcome a very natural tendency to shut his eyes and shrink from the recoil of his piece at the moment of its discharge, while the trained soldier may thereby conveniently and economically preserve and improve that accord between the brain and the muscles without which the best marksmanship is impossible. See *Target-practice*.

GALLIC SWORD.—This sword was made of bronze. It was long, sharp-pointed, edged on both sides, and in the graceful curves of its form it somewhat resembled the leaf of the sage-plant. The weapon was like the Greek sword in general appearance.

GALLING FIRE.—The sustained discharge of cannon or small-arms, which by its execution greatly annoys the enemy.

GALLIVATS.—Large row-boats, formerly and still to some extent used in Eastern waters. They rarely exceed seventy tons, carry two masts with high triangular sails, and are generally armed with a few small swivel-guns, fastened on the bulwarks. The Malay pirates employ these swift but rather fragile vessels.

GALLOP.—The word of command in the School of the Soldier Mounted, by which the trooper is directed to cause his horse to lift alternately the fore-feet and the hind-feet together, in successive leaps or bounds. The horse gallops on the *right foot* when the right fore and hind legs move in advance of the left fore and hind legs; he gallops on the *left foot* when the left fore and hind legs are in advance. He gallops *true* when he gallops on the right foot in marching to the right hand, or on the left foot in marching to the left hand; and gallops *false* if, in marching to the right hand, he gallops on the left foot, or conversely. A horse is *disunited* when he gallops with the near fore-leg followed by the off hind-leg, or the off fore-leg followed by the near hind-leg; in either case his center of gravity is deranged, and his strength impaired. When the horse gallops on the left foot the rider feels a sensible movement in his position from left to right; when he gallops on the right foot the movement of the rider is from right to left; when the horse is disunited the rider experiences irregular movements. To cause the horse to gallop, gather him and keep him perfectly straight; carry the hand slightly forward, and to the left, to enable the right shoulder to move in advance of the left; close the legs behind the girth so as to urge the horse forward, causing him to feel the left leg most. When the horse obeys, keep the hand light that the gallop may be free and regular, and hold the legs close to keep him at the gait. To keep a horse true the rider must accommodate himself to all his motions, particularly in changing direction.

GALLOPER.—A carriage on which very small guns are conveyed, having shafts on which the gun may be borne without a limber. This carriage is seldom or never used in late years.

GALLOPER-GUNS.—Light guns of small caliber. Formerly these guns were attached to English infantry regiments, but they have long been abolished.

GALLOWGLASS.—In ancient times, a heavy-armed foot-soldier of Ireland and the Western Isles.

GALVANISM.—That branch of the science of electricity which treats of the electric currents arising from chemical action, more particularly from that attending the dissolution of metals. It is sometimes called dynamical electricity, because it deals with current electricity, or electricity in motion, and is thus distinguished from frictional electricity, which is called statical in consequence of its investigating the electric condition of bodies in which electricity remains insulated or stationary. These terms, although in the main thus properly applied, are in all strictness applicable to both sciences. Frictional electricity, though small in quantity, can pass in a sensible current, and galvanic electricity, though small in tension, can be made to manifest the attractions and repulsions of stationary electricity. Thus the series of discharges which are transmitted in a wire connecting the prime conductor of a machine in action with the ground possesses, though feebly, the characteristics of a galvanic current; and the insulated poles of a many-celled galvanic battery manifest before the current begins the electric tension of the friction-machine. The other branches of current electricity will be found under INDUCTION OF ELECTRIC CURRENTS, MAGNETO-ELECTRICITY, and THERMO-ELECTRICITY. The science of galvanism dates from the close of the eighteenth century. In the year 1780, Galvani, in making investigations on the nervous irritability of cold-blooded animals, discovered by accident that the limbs of a recently killed frog, when hung by the crural nerve on a metal support near an electric machine, contracted convulsively at the recurrence of each spark. This he properly accounted for by the back-stroke. Six years afterwards, in experimenting on atmospheric electricity with frog limbs as delicate electroscopes, he obtained, also accidentally, the same convulsions by bringing the copper hook on which the nerve hung, and the limb itself, simultaneously in contact with an iron railing. The similarity of the result led him to attribute it to the same cause—viz., electricity either existing in the limb itself or produced in the conducting arc of metal. On consideration, he adopted the former hypothesis, and looked upon the limb as a self-charging Leyden jar, with the nerve as the brass knob and wire, the interior of the muscle as the inner coating, its exterior the outer coating, and the metal arc as the discharging tongs. He first published his researches in 1791. Volta, 1792, discarded the account given by Galvani of his experiment; and from the fact that the convulsions in question took place with more energy when there were two metals in the conducting arc instead of one, attributed the source of electricity to the heterogeneity of the metals employed. He maintained that at the surface of contact of two different metals an electric force arising from their heterogeneity is generated, which throws them into different tensions. This doctrine forms the fundamental principle of the *contact theory* of galvanism. In reply to

Volta, Galvani proved incontestably that the contraction in the limbs of the frog took place when only one metal was employed, and even when the conductor was not of metal at all. Subsequent discovery has proved Galvani to be partly right in attributing the cause of these convulsions to animal electricity, and Volta also to be partly right in attributing them to electricity generated in the metal arc, for both causes may be at work in producing the result. Volta's theory of contact is still maintained, though another theory obtains no less support which attributes the source of galvanic electricity to the chemical action of a liquid on a metal coupled with another metal less easily acted on than itself. Fabroni, a Professor at Florence, was the first (1792) to suggest chemical action as one of the causes at work in Galvani's experiment. Volta did not accept of Galvani's vindication, but supported his theory by several apparently conclusive experiments. In 1799 he constructed, as the crowning evidence of the truth of his reasoning, his pile, and with it properly begins the history of galvanism. To Galvani is thus due the merit of discovering a new manifestation of electricity; to Volta is due the merit of displaying in it a source of power of incalculable importance, and which, but for his genius, might have remained among the barren curiosities of science. Hence it becomes a question of some difficulty to decide to which of the two the science we are discussing owes its origin—whether it is to be called Galvanism or Voltaism. Priority of discovery has led men generally to decide in favor of Galvani, although Volta has almost equal claim to have his name attached to the science. The first account of Volta's pile reached England in a letter to Sir Joseph Banks by the inventor (1800). A few weeks afterwards Carlisle and Nicholson decomposed water with it, and afterwards several salts. They were the first to use platinum electrodes. Davy, in the same year, traced the electricity of the pile to chemical action. Wollaston (1801) reiterated the same theory, and went the length of attributing even frictional electricity to chemical action. He proved likewise the identity of the two electricities, and showed that by diminishing the electrodes to mere points, the electricity of the machine could produce the same chemical effects as that of the pile. In 1802 Cruikshank improved the construction of the pile by disposing the plates horizontally in a trough instead of vertically in column. The main features of electro-chemical decomposition were discussed by Davy in his famous Bakerian lecture of 1806. In 1807 the same philosopher obtained, for the first time by galvanic agency, the metals potassium, sodium, barium, strontium, calcium, and magnesium. Deluc (1809) first made dry piles of gold and silver paper, and these were altered and improved by Zamboni (1812). In 1813 Davy discovered the electric light and voltaic arc by means of the colossal battery then placed at his disposal at the Royal Institution. Œrsted (1820) first observed the action of the current on the magnetic needle; and a few months afterwards Ampere discovered the law of this action, and originated an electric theory of magnets which has proved wonderfully fertile in practical results. In the same year Schweigger invented the galvanometer. In 1825, Becquerel, with the aid of his differential galvanometer, investigated the conductibility of metals. Kemp, in 1826, first used amalgamated zinc for the galvanic battery. In 1827 Ohm gave a mathematical theory of the pile, rigidly deduced from Volta's fundamental principle, and in perfect keeping with experiment. Faraday (1831–32) published his discoveries of the induction of electric currents, and of the evolution of electricity from magnets, which have since enriched the science with the induction-coil and the magneto-electric machine. This distinguished electrician discovered (1833–34) the definite nature of electro-chemical decomposition, and proved that electro-chemical and chemical equivalents were identical. In 1836 Daniell constructed his constant battery. Spenser in England, and Jacobi in Russia, made, simultaneously (1837), the discovery of electro-metallurgy. Grove (1839) constructed his nitric-acid battery. Faraday (1840) gave his proof of the truth of the chemical theory. Smee's battery dates also from this year. In 1843 Wheatstone, by means of his rheostat and resistance-coils, investigated the resistances offered by various conducting substances to the current. In the same year Bunsen introduced his carbon battery. The rivalry between the chemical and contact theorists has favored the advancement of the science, each party calling in the aid of experiment to support their views. Among the more distinguished contact theorists may be mentioned Volta, Ritter, Pfaff, Biot, Deluc, Ohm, and Fechner; and among the chemical theorists, Fabroni, Davy, Wollaston, Parrot, De La Rive, and Faraday. Davy latterly maintained a theory of distribution and equilibrium of electricity midway between the two, which numbered among its supporters Jæger, Berzelius, Ermann, and Prechtl. Recently (1860 onwards), Sir William Thomson has given what he considers to be convincing proofs of Volta's contact theory, but he modifies the theory so far as to render it consistent with the conservation of force.

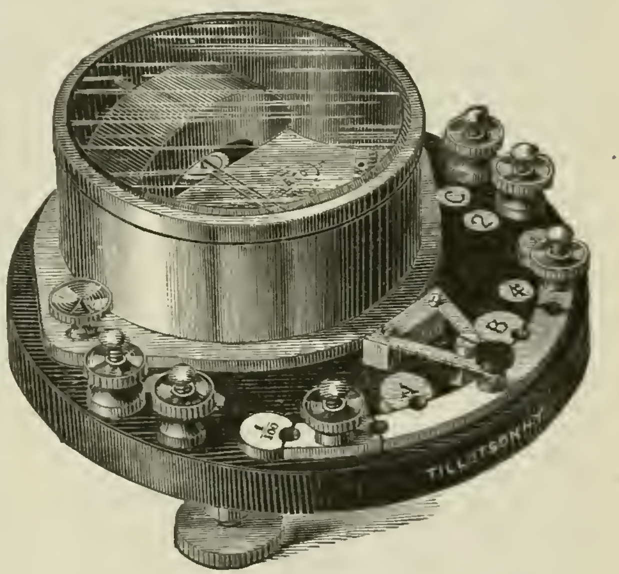


FIG. 1.

When two plates of copper and amalgamated zinc (zinc whose surface has been rubbed over with mercury) are placed in a vessel containing water to which a small quantity of sulphuric acid has been added, so long as they are kept from touching, either within or without the liquid, they remain apparently unaffected. If, however, they be made to touch, bubbles of hydrogen gas are formed in abundance at the copper plate, and their formation continues until the plates are again separated. If the contact be maintained for some time, and the plates and liquid be afterwards examined, it is found that the copper plate weighs exactly the same as before, that the zinc plate has lost in weight, and that the liquid contains the lost zinc in solution in the form of the sulphate of that metal. The contact need not be affected by the plates themselves. If wires of copper, or any other conductor of electricity, be soldered to the plates, or fixed to them by binding-screws, and be made to touch, the changes just mentioned take place as if the plates were in contact. When the wires are thus joined and, so to speak, form one connecting wire between the plates, they exhibit very peculiar properties. If a portion of the connecting wire be placed parallel to a magnetic needle, and the needle brought near, its north end no longer points to the north, but to a point either to the east or west of it, and this deviation ceases with the separation of the wires. It is not even necessary that the wires be in contact, for if their ends be put into a vessel containing a conducting liquid the same changes occur, though to a diminished extent, the contact being completed through the liquid. The ends of the wires, when so immersed, show strong chemical affinities. If the conducting liquid were a solution of the sulphate of copper, the wire from the zinc becomes coated with the copper of the solution, whilst the other attracts its oxygen and sulphuric acid, and wastes away in entering into combination with them. The connecting wires are found, therefore, in actual or virtual combination, to possess very marked magnetic and chemical properties. The arrangement just described constitutes a *galvanic pair*, which may be generally defined to be *two dissimilar conducting plates immersed in a liquid which can act chemically on one of them, and capable of being placed in conducting connection:* and the properties just referred to form the characteristic powers of galvanic electricity. These properties arise from the wires in connection being the seat of a constant discharge or flow of electricity, for they are possessed, though to a very feeble extent, by the electricity of the friction electric machine. If the prime conductor of a powerful electric machine be connected with one of the binding-screws of an insulated galvanometer, and a wire connected with the ground be fixed into the other, the plate on being turned causes a current of electricity to pass from the machine to the ground through the coil of the galvanometer, the needle of which will then show a deviation of one or two degrees. The deviation, so far as direction is concerned, is the same as that which would be produced by placing the wires coming from the copper and zinc respectively in the same binding-screws as those connected with the machine and the ground. This would indicate that the copper plate stands electrically in the same relation to the zinc plate as the prime conductor of the machine to the ground. The electricity of the conductor is positive, and that of the ground by induction negative; so that in the galvanic pair the copper plate, by analogy, gives off the positive electricity, and the zinc plate negative. Again, let the wire from the machine end in an insulated vessel containing a solution of the sulphate of copper, and let the end of a fine platinum wire connected with the ground be made to dip below the surface of the solution, and let the machine be kept in action so as to send a current of electricity through the wires and liquid: at the end of some minutes the point of the platinum wire will be covered with a minute quantity of copper. The wire connected with the zinc in the galvanic pair and that connected with the ground are thus shown to display the same chemical power; and this, again, shows us that the zinc plate, like the ground in the above experiment, is the seat of negative electricity. The electric condition of the plates before contact reveals, with the aid of a delicate electrometer, positive electricity in the copper plate, and negative in the zinc plate. If the wire joined to the zinc plate, or, as we may write it shortly, zinc wire (not, however, necessarily a zinc wire), be connected with the ground, and the insulated copper wire be made to touch the lower plate of a condenser whilst the finger touches the upper, on both being withdrawn, the leaves of the electroscope diverge with the positive electricity sent to it from the copper plate. It can be shown, moreover, that the current is not confined to the connecting wire, for if a magnetic needle be suspended between the plates when they lie north and south, slightly above the surface of the liquid, it will deviate from its usual position when the wires are joined, and in the opposite way to that which it shows when held above the wire placed in the same direction. The current thus passes within the liquid from the zinc to the copper the opposite way to that in which it runs in the connecting wires, so that it makes a complete circuit. Hence we may conclude, generally, that *in the galvanic pair a current of electricity runs within the liquid from the chemically active to the chemically passive plate, and without the liquid, from the chemically passive to the chemically active plate, making a complete circuit;* and that if the connection be interrupted the pair shows electric polarity, the *chemically passive plate being the positive pole, and the chemically active plate the negative pole.* The theory of the action of the galvanic pair may be thus given. When the two plates are put into the water and sulphuric acid they assume opposite electric states. There is developed

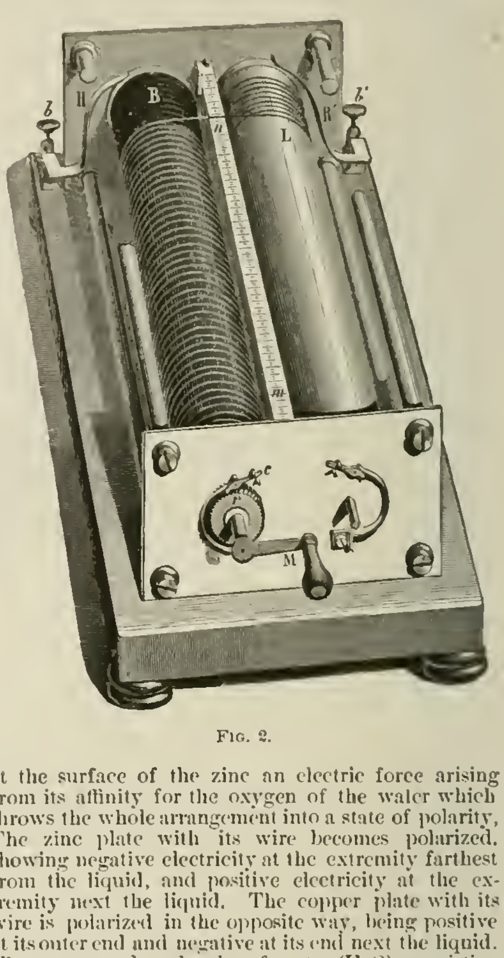

Fig. 2.

at the surface of the zinc an electric force arising from its affinity for the oxygen of the water which throws the whole arrangement into a state of polarity. The zinc plate with its wire becomes polarized, showing negative electricity at the extremity farthest from the liquid, and positive electricity at the extremity next the liquid. The copper plate with its wire is polarized in the opposite way, being positive at its outer end and negative at its end next the liquid. The compound molecules of water (H_2O), consisting of oxygen (O) and hydrogen (H_2), are likewise polarized, but the polarization takes place in the individual molecules. It appears, moreover, to have reference to their compound nature, and we may imagine them placed in series, with their oxygen or negative pole toward the zinc, and their hydrogen or positive pole towards the copper. When the ends of the wires are brought near each other, we might anticipate that a spark discharge would restore quiescence. This, however, is not the case, for the electric tension is so low that nothing short of contact can effect a discharge. When the discharge thus takes place, the polarity of the circuit for the instant ceases; the tendency to union of the zinc with the atom of oxygen next it is completed by the formation of the oxide of zinc. But in order to accomplish this, the hydrogen of the molecule of water next the zinc thus set free unites with the oxygen of the neighboring molecule to re-form the water, and the same transference and union is continued along the whole series until the hydrogen of the molecule next the copper is thrown on the copper, where, being unable to unite chemically with it, it is given off as a gas. From the fact that pure water has almost no action on zinc, a more probable hypothesis is held that it is not the water but the sulphuric acid (H_2SO_4) that is concerned in the action. We have H_2 as before; but instead of O we have SO_4, a compound molecule forming zincic sulphate (Zn_2SO_4) at once. In either case the zinc is left clean, either by the acid dissolving the oxide or the water present dissolving the sulphate. After the first discharge, therefore, the whole is as at first, so that a second discharge instantly follows, then a third, and so on. A series of discharges is thus transmitted through the circuit, constituting what is known as a current.

In a wire where a current of galvanic or frictional electricity is passing there is no point which forms the seat of positive or negative electricity, but it appears electrically homogeneous throughout. It exerts no statical inductive action on surrounding objects, neither attracting nor repelling them, for the electric action being more easily propagated along the wire than in any other direction, takes place only in it. The laws of induction and distribution applicable to frictional statical electricity hold true in a current electricity only at the section of the wire or conductor along which the action is transmitted. As tested by the magnetic needle, there is no part of the circuit which possesses more power than another. This homogeneity gives rise to the hypothesis that every molecule of the circuit, whether solid or liquid, acts in the transmission of the electric force, and is similarly affected in its passage. In this way the plates and connecting wires show the same molecular polarity as the liquid, only the discharge does not effect an interchange among the molecules, but leaves them in the same condition as before. Each molecule of the connecting wire may be viewed to be the seat of electric polarity and discharge with its negative faces turned towards the copper, and its positive towards the zinc; whenever, therefore, we go with the current we meet each molecule on its negative side, and whenever we go contrary to the current we meet each molecule on its positive side. Any portion of the circuit shows its negative face to the approaching current, and its positive face at the other extremity. A break in the connecting wire thus separates two contiguous molecules; that ending the copper wire shows itself positive, and that ending the zinc wire negative. This is in perfect keeping with experiment, for wherever a break or change of medium is made in the circuit without stopping the current—as in the electric light, chemical decompositions, the visible passage of electricity in vacuous tubes, and the like—the ends or poles exhibit opposite powers, from the pole meeting the current discharging negative, and the other positive, electricity. The polarity displayed at such interruptions, or visible passages of the current, is necessarily different from the polarity of frictional electricity, for the dynamical manifestation of electric force cannot be the same as the statical; in the same way that motion, for instance, the dynamical manifestation of the force of gravity, is essentially different from weight, or its statical manifestation. Within the galvanic pair itself the same polarity is shown: the zinc plate, without the liquid or the wire connected with it, is found to act as a negative pole, and the similar copper plate and wire as a positive pole; but within the liquid of the cell the zinc plate shows the same chemical affinities as the exterior positive pole, and the similar copper plate acts as the exterior negative pole. The terms positive and negative poles are merely relative, for every molecule or series of molecules would thus appear to have its opposite poles. They serve, however, conveniently to express the relations of two consecutive parts of the circuit. Considerable confusion sometimes arises from speaking of the zinc plate as at once the positive element and negative pole, and the copper the negative element and positive pole of the galvanic pair, and such expressions seem even inconsistent. The truth is that the zinc and copper plates must have each both poles from the very nature of the circuit; but as the outer poles only of these plates are of practical importance, these are considered to be the poles. According to the one-fluid theory of electricity, a force is developed at the seat of the action which has the power of liberating the electric fluid, and of maintaining it in motion throughout the circuit, constituting a current in the true sense of the term. According to the two-fluid theory, two such currents, one of the positive and the other of the negative fluid, are made to move in opposite directions throughout the circuit. The propelling force is consequently termed *electromotive*, and the galvanic pair is called the *electromotor*. The terms current and electro-motive have their origin in the supposed fluidity of electricity, but being quite definite in their application, they may be used without any such admission. A current may be taken to signify, apart from all supposition, simply the peculiar electric condition of the conductor, which forms the line of discharge between a positive and a negative source of electricity, and electro-motive force may be used simply to denote that which propagates and maintains this discharge. In the same way, when we speak of the direction of the current, we only use a convenient way of showing at which end the positive and negative electricities arise, the current being always represented as moving from the positive to the negative. The greater the electro-motive force is, the more powerfully is the discharge effected, and the more is it able to force its way through imperfect conductors. It would seem probable that the source of the electro-motive force in the galvanic pair is the chemical action which takes place at the zinc plate. It must have appeared, even to the most cursory observer, highly probable that the seat of the most active change going forward in the pair is likewise the origin of the force accompanying it. It is found, moreover, when we tax the galvanic current with electro-chemical work, that the amount of work done by it is exactly proportionate to the quantity of zinc dissolved. These and similar considerations seem to argue strongly that galvanic action has its source in chemical action. Volta, however, and several of the most eminent authorities in the science, maintain that the electro-motive force has its seat at the surface of contact of heterogeneous metals, and that chemical action is not the cause but the manifestation of it. This view of the origin of galvanic electricity is called the *contact theory*, as distinguished from the *chemical theory*, the one we have hitherto followed. The contact theory supposes that at the surfaces of contact of two heterogeneous substances an electro-motive force, invariable in direction and amount, is generated and subject to modification only by the resistance offered by the conducting circuit. The galvanic pair is accounted for by this theory in the following way: Let us suppose, for the sake of explanation, that both zinc and copper plates are connected by copper wires. The seat of electromotive force is at the junction of the copper wire with the zinc. At this point the two metals assume opposite electricities—the copper the negative, and the zinc the positive; and since a conducting circuit through wires, plates, and liquid is established, these electricities travel in opposite directions, and, meeting, neutralize each other within the liquid, to give place to succeeding similar discharges of electricity. The discharge within the liquid takes place electrolytically. The theory is, in this case, sufficient and consistent, but it must be kept in mind that in a circuit so perfectly homogeneous the source of force may be placed anywhere without altering its conditions. It is, however, so far wrong in assuming that the contact of the metals, where there is no force lost or transformed, maintains a never-failing development of energy in the circuit—that, in fact, force can be created from nothing. Sir William Thomson and the modern advocates of the contact theory modify Volta's theory in this way. They admit with Volta that the contact of the metals charges them with different electricities, but that the chemical energy of the liquid in contact with the metals is necessary to discharge them and maintain the current. In the action of the pair three elements are to be considered—the *electro-motive force*, the *resistance*, and the *strength of the current*. The electro-motive force is proportional to the force tending to chemical action, if we adopt the chemical theory, or, on the contact theory, to difference of potential produced by the contact of the two metals. It is measured directly by the charge, or, as it is called, the potential (tension) which a cell gives to a delicate electrometer. In Thomson's reflecting quadrant electrometer, for instance, a single Daniell's cell deflects the needle so much that the spot of light moves some 2½ inches from the zero-point of the scale. The relative electro-motive powers of the various forms of cells can be ascertained by the amount of deflection indicated by such an instrument. The resistance in the circuit which is offered by the liquid of the cell and the interpolar wire or other connection, is that which tends to reduce the current or flow of electricity produced by the electro-motive force. As stated in Ohm's law, the current strength is equal to the electro-motive force divided by the resistance. The electro-motive forces of the different cells can also be compared by observing the effect, on the current strength, of a given resistance interposed in the relative circuits, whose own proper resistance has been previously known. The unit of electro-motive force now adopted by British electricians is called a *volt*. This is about 7 per cent less than that of a Daniell's cell. The unit of resistance is called an *ohm* or B. A. unit. 485 meters of pure copper wire 1 millimeter in diameter offer an ohm of resistance; so does about $\frac{1}{13}$ of a mile of ordinary telegraph-wire (No. 8). The unit of current strength is called a *farad*, and is the amount of flow of electricity that would be produced in a second if the cell of a volt in power were to act in a circuit of one ohm of resistance. One million volts are called a megavolt; one millionth of a volt, a microvolt. The same proportion holds for a megohm and a microhm, a megafarad and a microfarad. In the centimeter, gram, second series of electro-magnetic units, an ohm is expressed as 10^9, a farad as 10^{-1}, and a volt as 10^8.

When a number of copper and zinc pairs, similar to the one already referred to, are put together, so that the copper plate of one cell is placed in conducting connection with the zinc plate of the next, they constitute a galvanic battery. The term battery is sometimes also applied to a number of cells acting as one combination, in whatever way they may be connected. When the terminal copper and zinc plates are connected, the current runs from each copper to each zinc plate without the liquids, and from each zinc to each copper plate within the liquids; and when the contact is broken, the zinc pole shows negative, and the copper pole positive, electricity. The galvanic battery acts thus in all respects as a compound galvanic pair. If the polar wires be connected with a tangent galvanometer, the deflection of the needle caused by the battery will be exactly the same as that effected by one of the cells, provided the wire be thick and a good conductor; but if the zinc end be connected with the ground, and the electric tension of the insulated copper pole be tested by a condenser and torsion-balance, its tension is found to be as many times greater than the tension of the same pole of one cell examined in the same way as there are cells in the combination. Thus, if two cells be taken, the tension is doubled; if three, tripled; and so on. *The electro-motive force of a battery is therefore proportional to the number of cells*, supposing, of course, that they are arranged consecutively. Hence the electricity of a battery is better able to force its way through imperfect conductors than that of the simple pair. When the interpolar communication is formed by a thick short wire, a single cell produces as powerful an effect on the magnetic needle as a battery; but if it be formed by a bad conductor, such as a long and thin wire, or a liquid, the effect is very different. The current of the pair is then nearly stopped, and its influence on the needle small, while that of the battery continues to flow comparatively unimpaired. When a battery is put up in series, it is said to have a tension arrangement; when put up so that several of the cells are grouped together, so as to act as one large cell, it is said to have a tension arrangement. Thus 20 cells are arranged for tension when joined in succession; but they may be disposed so as to act as one large cell 20 times as large, or as

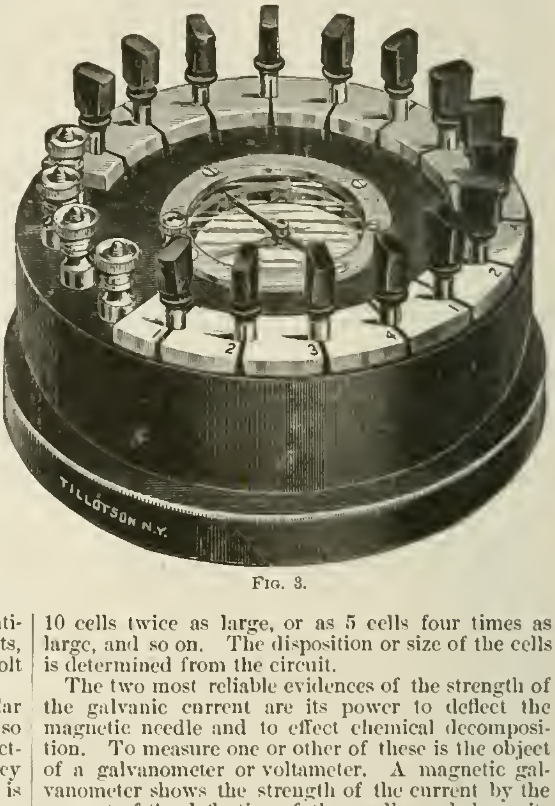

FIG. 3.

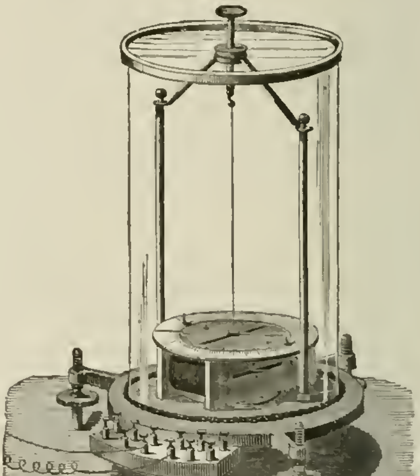
10 cells twice as large, or as 5 cells four times as large, and so on. The disposition or size of the cells is determined from the circuit.

The two most reliable evidences of the strength of the galvanic current are its power to deflect the magnetic needle and to effect chemical decomposition. To measure one or other of these is the object of a galvanometer or voltameter. A magnetic galvanometer shows the strength of the current by the amount of the deflection of the needle, and shows its direction by the way in which it deflects, as explained in the article GALVANOMETER. The *tangent galvanometer* consists essentially of a thick strip of copper, bent into the form of a circle, from one to two feet in diameter, with a small magnetic needle, moving on a graduated circle, at its center. When the needle is small compared with the ring, it may be assumed that the needle in any direction it lies holds the same relative position to the disturbing power of the ring. This being the case, it is easy to prove that *the strengths of currents circulating in the ring are proportionate to the tangents of the angles of deviation of the needle.* Thus, if the deflection caused by one galvanic couple was 45°, and of another 60°, the relative strengths of the currents sent by each would be as the tangent of 45 to the tangent of 60°—viz., as 1 to 1.73. The needle can never be deflected 90°, for since the tangent of 90° is infinitely large, the strength of the deviating current must be infinitely great, a strength manifestly unattainable. The tangent galvanometer can consequently be used to measure the strongest currents. The *differential galvanometer*, adapted to the requirements of battery-tests and all fine, accurate measuremen of resistances, is shown in Fig. 1 It is used with the rheostat to measure any resistance from one one-hundredth of an ohm upward. The *voltameter* was invented by Faraday for testing the strength of a current. In this apparatus two platinum plates, each about half a square inch in size, are placed in a bottle containing water acidulated with sulphuric acid; the plates are soldered to wires which pass up through the cork of the bottle; binding-screws are attached to the upper ends of these wires; a glass tube fixed into the cork serves to discharge the gas formed within. When the binding-screws are connected with the poles of a battery, the water in the bottle begins to be decomposed, and hydrogen and oxygen rise to the surface. If, now, the outer end of the discharging-tube be placed in a trough of mercury (mercury does not dissolve the gases), and a graduated tube, likewise filled with mercury, be placed over it, the combined gases rise into the tube, and *the quantity of gas given off in a given time measures the strength of the current.* The voltameter chooses as a test the work which the current can actually perform, and establishes a uniform standard of comparison. The indications of the tangent galvanometer are comparable only with its own, but the quantity of gas discharged by the voltameter, corrected for pressure and temperature, is something quite absolute. However, by comparing the indications of both instruments with each other when placed in the same circuit, an absolute standard may likewise be got for the tangent galvanometer. If, for instance, the current given by a battery should give 60 cubic centimeters of gas in a minute, and produced at the same time a deflection of 45° in the galvanometer, the ratio of 60 to the tangent of 45°—viz., 60 to 1 = 60—is constant, for correct measurements of the strength of currents, however taken, must bear to each other a constant ratio. If the angle of deviation for another current was 30°, we have therefore only to multiply 60 by the tangent of 30°, to ascertain the amount of gas that would be liberated by a current of that strength in a minute. This found, we know the meaning of a deflection of 30° of the galvanometer in question in a perfectly comparable standard. The plates of the voltameter must be small, for when they are large a small quantity of electricity is found to pass without decomposing the water. It is found also that a minute quantity of the oxygen forms hydric peroxide with the water, and remains in solution, so that when very great accuracy is required the hydrogen alone ought to be measured.

It is found that the dimensions and material of substances included in the circuit exercise an important influence on the strength of the current. It is of the greatest importance to ascertain the relative amount of the resistance offered by conductors of various forms and materials. The *rheostat*, invented by Wheatstone, is generally employed for this purpose, and for this object is constructed so as to introduce or withdraw a considerable amount of highly resisting wire from the circuit without stopping the current. It is represented in Fig. 2. Two cylinders, B, L, about 6 inches in length and 1½ inches in diameter, are placed parallel to each other, both being movable round their axis. One of them is of brass, the other is of well-dried wood. The wooden cylinder has a spiral groove cut into it, making forty turns to the inch, in which is placed a fine metallic wire. One end of the wire is fixed to a brass ring, and its other end is attached to the nearer end of the brass cylinder. The brass ring just mentioned is connected with the binding-screw b' by a strong metal spring. The further end of the cylinder, B, has a similar connection with the binding-screw b. The key, M, fits the projecting staple of either cylinder, and can consequently turn both. As the brass cylinder, L, is turned in the same direction as the hands of a watch, it uncoils the wire from the wooden cylinder, B, making it thereby revolve in the same way. When the wooden cylinder is turned contrary to the hands of a watch, the reverse takes place. The number of revolutions is shown by a scale, *mn*, placed between the two, and the fraction of a revolution is shown by a pointer moving on a graduated circle. When the binding-screws b and b are included within a circuit, say b' with the positive, and b with the negative pole, the curreut passes along the wire, on the wooden cylinder, till it comes to the point where the wire crosses to the brass cylinder; it then passes up the cylinder B to the spring and binding-screw b. The resistance it encounters within the rheostat is met only in wire, for as soon as it reaches the large cylinder the resistance it encounters up to b may be considered as nothing. When the rheostat is to be used, the whole of the wire is wound on the wooden cylinder, the binding-screws are put into the circuit of a constant cell or battery along with a galvanometer, astatic or tangent. If, now, the resistances of two wires are to be tested, the galvanometer is read before the first is put in the circuit. After it is introduced, in consequence of the increased resistance offered by it, the needle falls back, and then as much of the rheostat wire is unwound as will bring the needle back to its former place. The quantity of wire thus uncoiled in the rheostat is shown by the scales, and is manifestly equal in resisting power to the introduced wire. The first is then removed, the rheostat readjusted, and the second wire included, and the same unwinding goes on as before. To fix our ideas, let the quantity of wire unwound in the first case be 40 inches, and in the second case 60 inches; 40 inches of the rheostat wire offer as much resistance to the current as the first wire, and 60 inches of it as much as the second. We have thus 40 to 60 as the ratio of the resistances of the two wires. The wire of the rheostat, from its limited length, can only be comparable with small resistances; and where great resistances are to be measured, supplementary *resistance-coils* of wires, of a known number of ohms, are introduced into the circuit, or removed from it, as occasion requires, leaving to the rheostat to give, as it were, only the fractional readings. This being premised, it will be easily understood how the following results have been ascertained. It is proved, for instance, that the *resistances of wires of the same material, and of uniform thickness, are in the direct ratio of their lengths, and in the inverse ratio of the squares of their diameters.* Thus a wire of a certain length offers twice the resistance of its half, thrice of its third, and so forth. Again, wires of the same metal, whose diameters stand in the ratio of 1, 2, 3, etc., offer resistances which stand to each other as 1, ¼, ⅑, etc.; therefore the longer the wire the greater the resistance; the thicker the wire the less the resistance. The same holds true of liquids, but not with the same exactness. For this reason, the larger the plates of a galvanic pair, and the nearer they are placed to each other, the less will be the resistance offered to the current by the intervening liquid. The following table of the resistances, expressed in ohms, offered by a wire one meter long and one millimeter in diameter at 0° Centigrade, has been determined by Dr. Mathiessen: silver annealed, 0.01937; copper annealed, 0.02057; gold annealed, 0.02650; aluminium annealed, 0.03751; zinc, 0.07244; platinum annealed, 0.1166; iron annealed, 0.1251; tin, 0.1701; lead, 0.2526; mercury, 1.2247; and German silver, 0.2695. With copper at 32° F. as 1, the following liquids stand thus: saturated solution of the sulphate of copper, at 48° F., 16,885,520; ditto of chloride of sodium at 56° F., 2,903,538; sulphate of zinc, 15,861,-267; sulphuric acid, diluted to $\frac{1}{12}$, at 68° F., 1,032,-020; nitric acid, at 55° F., 976,000; distilled water, at 59° F., 6,754,208,000. The slightest admixture of a foreign metal alters the resistance very decidedly: ½ per cent of iron in copper wire increases the resistance more than 25 per cent. It has been found also that the resistance offered by a wire increases as its temperature rises. It is almost needless to add that the conducting powers of metals are inversely as their specific resistances, the least resisting being the best conducting. A combined galvanometer and rheostat, made specially for field-service, is represented in Fig. 3. It is much used for measuring the resistance of all instruments, batteries, and lines not exceeding two thousand ohms. It is graduated from one tenth of an ohm upward, is accurately adjusted for exact, quick tests, and is found invaluable in testing circuits, apparatus, etc., and in locating faults. The apparatus is very portable, weighing, complete, only five pounds. See *Daniell Battery, Electricity, Electric Light, Electrolysis, Firing-battery, Galvanometer, Induction of Electric Currents, Magneto-electricity*, and *Ohm's Law*.

GALVANOMETER. — Two of the most reliable evidences of the strength of the galvanic current are its power to deflect the magnetic needle, and to effect chemical decomposition. To measure one or other of these is the object of a galvanometer or voltameter. A magnetic galvanometer shows the strength of the current by the amount of the deflection of the needle, and shows its direction by the way in which it deflects. The manner in which a needle should turn when influenced by a current is easily kept in mind by Ampere's rule: *Suppose the diminutive figure of a man to be placed in the circuit, so that the current shall enter by his feet, and leave by his head; when he looks with his face to the needle, its north pole always turns to his left.* The deflecting wire is supposed always to lie in the magnetic meridian. The *astatic galvanometer*, or *galvanometer*, is used either simply as a galvanoscope, to discover the existence of a current, or as a measurer of the strengths of weak currents. When a needle is placed under a straight wire, through which a current passes, it deflects to a certain extent, and when the wire is bent, so as also to pass below the needle, it deflects still more. This is easily understood from the above rule. The supposed figure has to look down to the needle when in the upper wire, and to look up to it in the lower wire, so that his left hand is turned in different ways in the two positions. The current in the upper and the lower wire moves in opposite directions, thus changing in the same way as the figure; and the deflection caused by both wires is in the same direction. By thus doubling the wire, we double the deflecting force. If the wire, instead of making only one such circuit round the needle, were to make two, the force would be again doubled; and if several, the force (leaving out of account the weakening of the current caused by the additional wire) would be increased in proportion. If the circuits of the wire be so multiplied as to form a coil, this force would be enormously increased. Two needles, as nearly the same as possible, placed parallel to each other, with their poles in opposite ways and suspended, so as to move freely, by a thread without twist, have little tendency to place themselves in the magnetic meridian, for the one would move in a contrary direction to the other. If they were exactly of the same power, they would remain indifferently in any position. They cannot, however, be so accurately paired as this, so that they always take up a fixed position, arising from the one being somewhat stronger than the other. This position is sometimes in the magnetic meridian, sometimes not, according as the needles are less or more perfectly matched. Such a compounded needle is called *astatic*, as it stands apart from the directing magnetic influence of the earth. If an astatic needle be placed in a coil, so that the lower needle be within the coil, and the upper one above it, its deflections will be more considerable than a simple needle, for two reasons: in the first place, the power which keeps the needle in its fixed position is small, and the needle is consequently more easily influenced; in the second place, the force of the coil is exerted in the same direction on two needles instead of one, for the upper needle being much nearer the upper part of the coil than the lower is deflected alone by it, and the deflection is in the same direction as that of the lower needle. An astatic needle so placed in a coil constitutes an astatic galvanometer. Round an ivory bobbin, in one of these instruments, a coil of fine copper wire, carefully insulated with silk, is wound, its ends being connected with binding-screws. The astatic needle is placed in the bobbin, which is provided with a vertical slit to admit the lower needle, and a lateral slit to allow of its oscillations, and is suspended by a cocoon thread to a hook supported by a brass frame. The upper needle moves on a graduated circle; the compound needle hangs freely, without touching the bobbin. The whole is included in a glass case, and rests on a stand supported by three leveling-screws. When used, the bobbin is turned round by a screw until the needle stands at the zero-point, and the wires through which the current is sent are fixed to the binding-screws. The number of degrees that the needle deflects may then be read off. Very sensitive galvanometers, now taking the places of all others in military mining, are those designed by Messrs. Queen and Company, United States. The engraving



Queen Convertible Galvanometer.

shows the instrument provided with leveling-screws and astatic needles, suspended from a brass arm by a fiber of unspun silk, with an arrangement for adjusting the zero of the scale to the axis of the coils. It is convertible by a moment's adjustment from an ordinary *quantity* galvanometer into one for *intensity*, or into a differential galvanometer for either *intensity* or *quantity*.

With these most essential instruments, the cables are from time to time examined to ascertain if their insulation is effective, and if they have a sufficient amount of electricity; if the firing-battery is in a condition to insure certain ignition; if the electrical connections of the circuit-closers are correct; if the electrical resistance of the fuse is such as to indicate certainty of ignition, and other similar information. A separate galvanometer should be used for each mine, and a special battery, distinct from the firing-battery, employed in connection with the testing-circuits; thus obviating the necessity of detaching the firing-battery while testing,—an important matter likely to occur at the critical period when vessels are attempting to break through the lines. Should any leak be discovered in a cable, the extent of it is shown by the galvanometer; and if considerable, the defective cable is detached from the battery and the fault repaired. When a mine is fired, it is important that its cable should be disconnected at once from the firing-battery, to prevent loss of power through the broken end of the conductor. When a separate galvanometer is supplied for each cable of a system of mines, it furnishes a constant indicator to point out the fact of a circuit-closer being struck by a ship, and in many cases it may be convenient, or even necessary, to perform the operation of throwing in the firing-battery without the aid of a personal operator. A self-acting apparatus has been devised for doing it. By making the apparatus purely self-acting, all chances of error consequent upon the inattention or want of dexterity of the man in charge is, of course, eliminated. No mine or circuit-closer can be tampered with by an enemy without the fact being instantly known in the testing-room, and precisely what mine. See *Galvanism*.

GAMA-GRASS.—A genus of grasses distinguished by unisexual flowers placed in spikes which are fertile at the base and barren towards the extremity, the spikelets having two glumes and about two florets, the female florets immersed in the thick and sinuous joints of the rachis, so that the spike, when the seed has ripened, presents the appearance of a cylindrical bone. Only two species are known of which the gama-grass of Mexico, distinguished by having spikes usually three together, has a high reputation as fodder-grass, is excellent for the stock in the field, and is cultivated not only in Mexico, but also in the United States of America, and to some extent in Europe. In favorable circumstances this grass yields a very abundant crop, and attains a height of nine or ten feet, its root-leaves measuring six feet in length. It possesses what for some climates is an almost invaluable property of bearing excessive drought without injury. It suffers, however, from frost. It seems eminently adapted to the climate of the Australian Colonies. The other species, the gama-grass of Carolina, distinguished by solitary spikes, is not so much esteemed.—Gama-grass is said to have derived its name from a Spanish gentleman who first attempted its cultivation in Mexico.

GAMBADO.—A case of leather formerly used to defend the leg from mud, and when riding on horseback.

GAMBESON—GAMBOISON.—A coat of mail worn under the cuirass. It consisted of a doublet of leather or linen cloth without sleeves, and quilted so that it was entirely covered with stitches. The high *gambeson* with cuishes and leggings, which in the fourteenth century was worn under the earliest suits of plate-armor, was also in leather or linen lightly quilted. Somtimes written *Gambesan*.

GAMELLE.—A wooden or earthen bowl formerly used among the French soldiers for their messes. It generally contained the quantity of food which was allotted for three, five, or seven men belonging to the same room. During the Monarchy of France subaltern officers and volunteers were frequently punished for slight offenses by being sent to the *gamelle* and excluded from their regular mess. On such occasions they were put upon short allowance, according to the nature of their transgressions.

GANG-DRILLS.—A number of drills so attached together, or to a common stock, as to act together. In a form of vertical gang-drill, much used in the manufacture of small-arms, the spindles are of steel, having anti-friction curved bearing at lower end, with take-up in boxes for wear, also answering the purpose of a step, doing away with the trouble caused by expansion in the length of spindle. The spindles are driven by a belt longer than is usually found on this class of drills, which overcomes the objection commonly raised against them. These drills, for armory purposes, are constructed in sizes as follows:

No.	No. of Spindle.	Size of Table.	Greatest Distance between Table and End of Spindle.	Length of Belt on Spindle.	Distance between Spindle-centers.	Center of Spindle to Column.	Diam. of Spindle.	Weight, lbs.
1	4	26 × 32 in. or smaller.	22 in.	5 ft. 9 in.	7⅜ in.	11 in.	1¼ in.	1,750
1	6	26 × 22 in. or smaller.	"	" "	4½ "	11 "	1¼ "	1,950
2	3	12½ × 22½ in.	20 in.	5 ft.	6 "	7½ "	1⅛ "	1,350
2	4	" " "	"	"	4 "	7½ "	1⅛ "	1,350
3	3	10 × 20 "	"	3 ft. 6 in.	5 "	7 "	1 "	720
3	4	" " "	"	" "	3½ "	7 "	1 "	720

No. 1 has 4-change cone-pulley for 3-inch belt. No. 2 has 3-change cone-pulley for 2¼-inch belt. No. 3 has 4-change cone-pulley for 2-inch belt. Pulleys on countershaft, Nos. 1 and 2, 12 inches diameter; No. 3, 10 inches diameter. Speed—No. 1, 250 revolutions; No. 2, 300 revolutions; No. 3, 350 revolutions, per minute. See *Drilling-machine*, *Drill-press*, and *Multiple Drill*.

GANGUE.—The stony matrix in which metallic ores occur. Quartz is the most common gangue, but calc-spar is also very frequent, sulphate of barytes and fluor-spar not unfrequent. Large portions of the gangue are generally worked and submitted to metallurgic processes for the sake of their contents. The term is also applied to the superfluous earthy matter of a smelting-furnace.

GANTLET—GAUNTLET.—A glove of iron which formed part of the armor of knights and men-at-arms. The back of the hand was covered with plates jointed together, so as to permit the hand to close. Gantlets were introduced about the thirteenth century. They were frequently thrown down by way of challenge, like gloves. They are frequently used in Heraldry, the fact of their being for the right or left hand being expressed by the words "dexter" or "sinister." In the phrase "To run the gantlet," the word is probably a corruption for *ganglope* (from *gang*, a passage, and the root occurring in e-*lope*—D. *loopen*, Ger. *laufen*, to run). The German has *gassenlaufen* (lane-run), meaning the military punishment, which consists in making the culprit, naked to the waist, pass repeatedly through a lane formed of two rows of soldiers, each of whom gives him a stroke, as he passes with a short stick or some other similar weapon. The term is frequently applied to a long glove covering the wrist and used generally as a riding-glove. See *Gloves*.

GANTLOPE—GANTLET.—A military punishment which consisted in making the culprit, naked to the waist, pass repeatedly through a lane formed by two rows of soldiers, each of whom gave him a blow with an iron glove or gantlet as he passed. Subsequently whips and canes were used instead of gantlets, until such a mode of punishment became obsolete. See *Gantlet*.

GAOL.—A withe used for binding fascines or securing gabions. Also a prison. See *Gabion*.

GARCON MAJOR.—An officer so called in the old French service. He was selected from among the Lieutenants of a regiment to assist the Aid Majors in the general details of duty.

GARDANT.—A term in Heraldry, said of an animal which is represented full-faced and looking forward. See *Passant-gardant*.

GARDE-FAUDE.—Over the flanks, on each side of the figure, to the *faudes* or *taces* was appended a plate or small shield, called a *garde-faude* (usually called *tuille* in England). These plates appeared in almost every variety of forms—square, hexagonal, lozenge-shaped, serrated, etc. In front and behind, the haubergeon was shown uncovered.

GARDE-GENERAL D'ARTILLERIE.—An officer, under the old Government of France, who had charge of all the ordnance and stores belonging to his Majesty for the land-service. He gave receipts for all ammunition, etc., and his bills were paid by the Treasurer General of the Army.

GARDE NATIONALE.—The Garde Nationale, the celebrated burgher defenders of order in Paris and certain other French towns, was for the first time introduced into Paris during the Revolution of 1789. It had existed for a long time previous in some of the French towns, having been at first employed to defend the rights and privileges of the city, and subsequently to guard the persons and property of the citizens. When, in July, 1789, the entire lower orders of the Capital rose and demanded arms, the leaders of the Revolution, sitting at the Hôtel de Ville, seized the opportunity to decree, without consulting the Government, the formation of a National Guard for Paris of 48,000 citizens, which, in the first instance, they named the Parisian Militia. Each electoral district was to enroll a battalion of 800 men, divided into 4 companies of 200 men each, 15 of these companies forming a legion. The officers of the battalions were to be elected by the privates; but the higher officers were named by the Committee. The device chosen as the badge of the service was of blue and red, the colors of the city, to which white, the color of the army, was added, to denote the intimate union which should subsist between the defenders of national liberty and the military. Thus arose the celebrated tricolor, afterwards adopted as the national badge, and now borne in honor wherever the French name extends. On the King consenting to the removal of the regular troops from Paris, Lafayette was named Commandant of the National Guard of the City. Ere many more days had elapsed, the friends of municipal freedom had organized themselves into burgher troops in every important town, and the National Guard had become a recognized institution of the whole kingdom, the entire number raised being not under 300,000. The force soon acquired an extraordinary degree of discipline and efficiency—in a great degree from the number of old soldiers who, having deserted the crown, were elected to commissions by the municipal troops. By an ordinance of June, 1851, the Garde Nationale was placed nearly on the footing of Louis Philippe's reign; but by a decree of 1852, which held till September 4, 1870, the entire force was dissolved, and reformed on a more military basis, in certain Departments only. During the Franco-Prussian War the Garde Nationale was divided into sedentary and active battalions. After the defeat of the Commune, in 1871, the French National Assembly decreed to dissolve the Garde Nationale, leaving the Prefects of Departments to choose the time of executing the decree. At present this body may be considered abolished, as its existence is incompatible with the new law of recruiting.

GARDE PLUIE.—A machine originally invented by a Frenchman, and submitted to the Prussians, who adopted it for the use of their infantry. Under the cover of these machines, the besieged or the troops stationed in the posts attacked would be able to keep up a brisk and effective discharge of musketry during the heaviest fall of rain, and thereby silence to some extent the fire of the enemy.

GARDE-REINS.—A part of the plate-armor of the Middle Ages, intended to protect the lower part of the back. See *Armor*.

GARDES-BRAS.—A piece of armor for the protection of the arms. See *Arm-guards*.

GARDES DE LA PORTE.—A company so called during the Monarchy of France, and of so ancient a date, indeed, with respect to original institution, that it appears to have been coeval with it. Mention is made of the *Gardes de la Porte* in the oldest archives or records pertaining to the King's Household, in which service they were employed, without being responsible to any particular Treasurer as other companies were. This company consisted of one Captain, four Lieutenants, and fifty Guards. The Captain and officers received their commissions from the King. The first took an oath of fidelity to the King in person, and accepted the bâton from his hands. His duties were purely discretionary. The Lieutenants served by detachment, and took their tours of duty every quarter. Their specific service consisted in guarding the principal gate belonging to the King's apartments. They were relieved at night by the body-guards, and delivered the keys to a Brigadier belonging to the Scotch garrison.

GARDES DU CORPS.—Under the old French Government, a certain number of gentlemen or cavaliers whose immediate duty was to attend the King's person. They were divided into four companies, under as many Captains, whose tour of duty came every quarter. They took rank above the Gens d'armes and the King's light cavalry. The first and most ancient of the four companies was called the Scotch Company, which was established by Charles VII. of France in 1423.

GARDES FRANCAISES.—A regiment formed by Charles IX., King of France, in 1563, for the immediate protection of the Palace. The Colonel of the Gardes Française was on duty throughout the year, and was entitled to the *bâton de commande* in common with the four Captains of the body-guards. Peculiar privileges were attached to every officer belonging to this body. No stranger, not even a native of Strasburg, Savoy, Alsace, or of Piedmont, could hold a commission in the French Guards. In the Revolution of 1789 they took a very active and leading part.

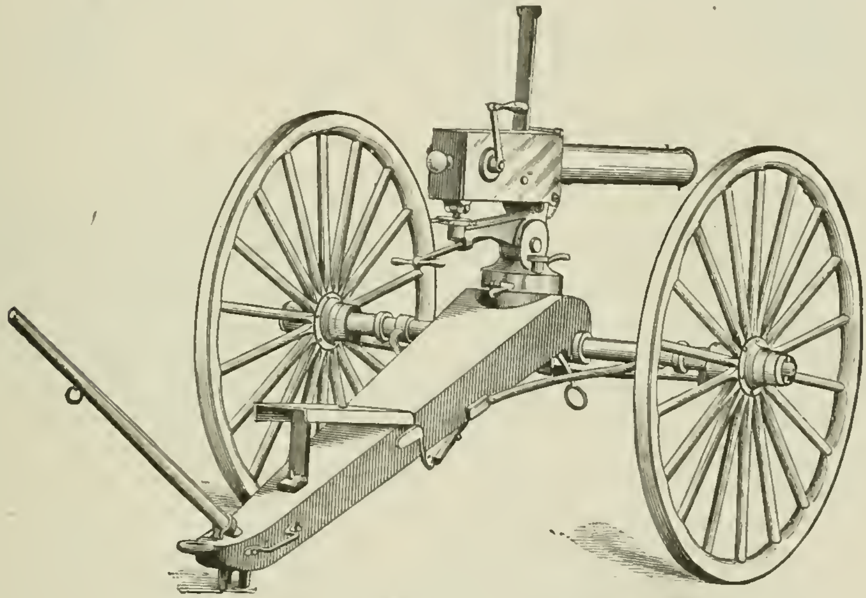
GARDES-MAGAZINS.—In the old French service there were two sorts of magazine-guards, one for the military stores and the other for the artillery. The first was subject to the Grand Master, and the second was appointed by the Secretary at War. *Gardes particuliers des magazins d'artillerie* were officers appointed by the Grand Master of Ordnance for the specific purpose of attending to the ammunition, etc. Their pay was in proportion to the quantity of stores with which they were intrusted.

GARDES SUISSES.—A celebrated corps in the French army, constituted "Gardes" by royal decree in 1616. They comprised upwards of 2000 men, were always unswerving in their fidelity to the Bourbon kings, and are quite remarkable for their heroic end. On August 10, 1792, they withstood the Parisian revolutionary mob, and defended the Palace of the Louvre till almost every man was cut down. During the resistance they offered, the Royal Family was enabled to escape to such shelter as the National Assembly afforded.

GARDE-VISURE.—The heraldic term used for what is commonly called the visor or front part of the helmet, used for the defense of the face and eyes.

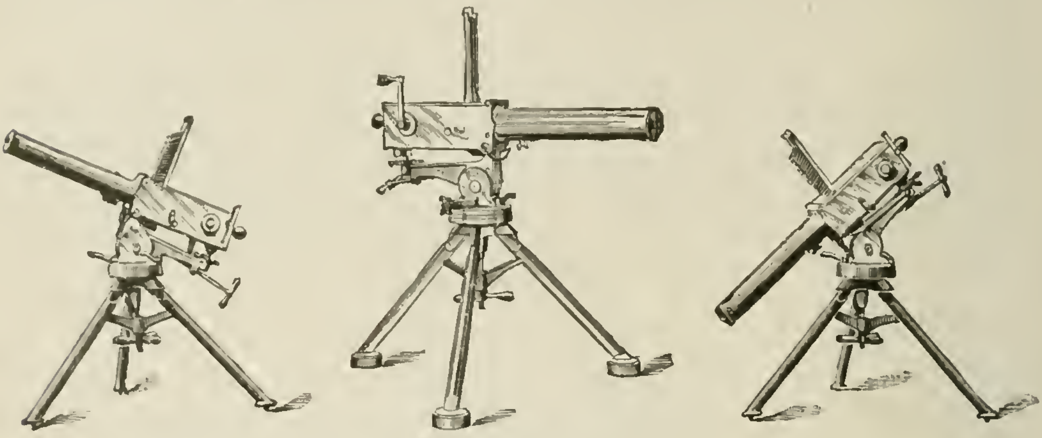
GARDNER MACHINE-GUN.—The improved Gardner gun, as shown on carriage and tripods, consists of two simple breech-loading rifle-barrels, placed parallel to each other, about 1.4 inch apart, in a *case* or *compartment*. These two barrels are loaded, fired, and relieved of shells by one revolution of the hand-crank. The working of the gun is simple. One man inserts the heads of cartridges projecting from a feed-block into the feed-guide, drawing the block from the cartridges; another man turns the crank by which the gun is fired, and as the cartridges disappear down the feed-guide, their places are supplied from another block: in this manner the firing may be made continuous. The barrels are open from end to end, and chambered at the rear to admit a flanged center-fire metallic cartridge. The barrels are firmly screwed into a *rear barrel-ring*, which is pinned fast to the rear case, and the muzzles pass through another similar ring called *front barrel-ring*, which is fitted into the front case and made fast with a taper pin. The rear case extends from rear barrel-ring far enough to contain all lock parts, together with the *driving-crank* and *safety-stop*. A swinging cover, hinged at forward end of case, is firmly locked in position by a cascabel having a screw-thread cut on its stem that enters the rear case. When the cover is raised, which can be quickly done after turning back the cascabel, all the working parts of the gun are fully exposed; and should an accident occur, like the bursting of cartridge-heads, or derangement of locks, the trouble can be instantly discovered, and as quickly remedied. The hand-crank that operates the gun is pinned fast to the *main crank*, which is supported by journal-boxes. The boxes are locked into the rear case, and serve as a protection to the swinging cover from side thrusts. The body of *main crank* is circular, having journals, or crank-pins, for operating the locks, diametrically opposite each other (the firing being alternate), and eccentric enough to give the required motion to the locks as they are moved forward and back, driving in cartridges and withdrawing shells. The outer portions of crank-pins or journals are flattened to the circle of the periphery of main crank for the purpose of holding the lock stationary while firing, about one-fifth part of revolution of hand-crank, and allowing ample time for *hang fires*. The lock in form resembles the letter U, having an extension from its side which contains the *firing-pin*, the main (spiral) spring, sector or spring compressor, sector-sleeve, extractor, and lock-head. The U part of the lock, that works under and around the crank-pin, is curved at the inner front to correspond with the outer circle of the crank; the office of the curved front being to hold the lock in position for firing. The circular firing-pin is flattened a portion of its length near the front end, to allow it to pass under the extractor by which it is held in position. It extends from the head of the lock through the mainspring and sector-sleeve, terminating in a flange or head for locking into a sear. The sear, having the form of a bell-crank, pivoted in the center to the lock, holds the firing-pin securely, and prevents it from touching the cartridge until it is released from its hold by the action of the crank-journal when the lock is in its extreme forward position. The sector, or spring compressor, hinged in a recess of the lock, and engaging, by means of gear teeth, with the sector-sleeve, has its arm forced against the safety-stop as the main crank advances, thus compressing, through the medium of the sector-sleeve, the mainspring, and holding it tense until released by action of the sear.

The lock-heads serve as breech-plugs, and receive the recoil when the cartridges are fired. Each lock carries a *hook extractor*, which rides over and catches the flange of the cartridge when the lock is forced forward, and when the lock retreats withdraws the empty shell until it comes within reach of the ejector, by which it is positively thrown out. The shell-starters have a positive movement in connection with the lock-head. Should the cartridge be driven by the extractor into the barrel, to its head (as is the case when the gun is worked rapidly), before the lock is in firing position, it is forced from the chamber by the shell-starter as the lock advances, and is held long enough for the extractor to engage with the head, when the lock, extractor, and cartridge are driven home together. The ejectors, hinged to the case, are driven by projections on the sides of the locks which give them positive movements to eject the empty shells. They also serve as stops to prevent cartridges from falling through the perforated plate as they are forced down through the feed-valve. The lock-guide extending across the rear case, to which it is fastened by a pin, has two parallel semicircular grooves, which are enlarged *extensions* of the chambers in barrels. From the back part of the groove, slots large enough to pass freely the cartridges (being wider at the rear, behind the ejector, than at the front) are cut downward through the plate. When the retractor has drawn the shell back nearly to the extent of the throw of the crank, the ejector forces the shell through the slot, and is then in position to receive another cartridge from the feed plate or valve. The feed-valve, attached to the swinging cover, has a reciprocating motion across the perforated plate. It has two angular openings of the size and shape of the outline of the cartridge, with centers equidistant with centers of barrels. After a cartridge has dropped one half its diameter into the valve, it is forced by the action of the latter into its true position, and held positively against the *cartridge-support*. When the valve is again moved back, the cartridge is forced downward into the perforated plate, and the column of cartridges is cut off in the swinging cover feed ways, which are extensions of the *feed-guide* that is located above and in line with the lock-guide. The feed valve is driven by the *feed-plate* lever; this also is attached to the swinging cover and is operated by the locks, using about one eighth the stroke of the crank in its forward motion, thereby giving the valve ample time to hold both cartridge and shell down in position as they move in and out from the barrel. The *feed-guide*



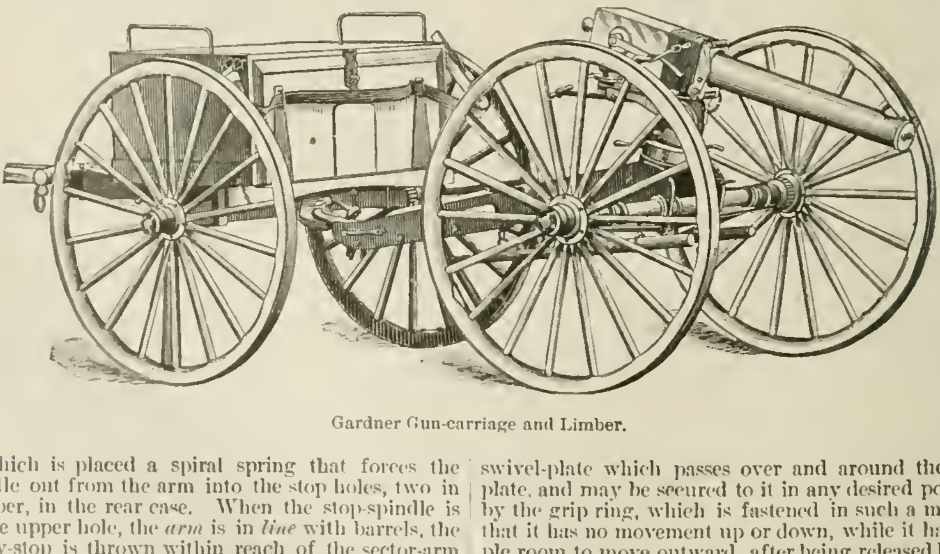
Gardner Machine-gun mounted on Carriage.

is a simple plate having two parallel T-grooves, extending from end to end, their centers equidistant with the centers of the barrels. The upper end of the guide has a trumpet shaped mouth to facilitate the entrance of the cartridge-heads. The lower end is provided with a cartridge stop, which lifts all cartridges contained in the guide when it is taken out from the swinging cover by which it is supported. The guide is held fast in firing position by a spring catch. It can be quickly released by drawing back



Gardner Machine-gun mounted on Tripod.

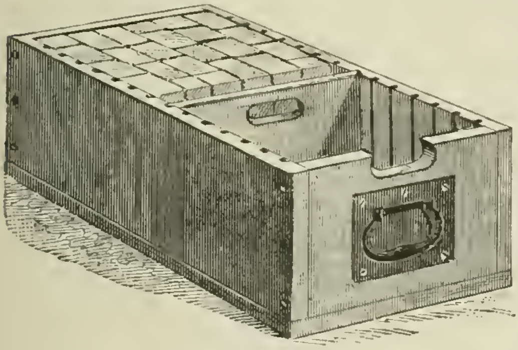
the spring catch by pressure on its exposed arm. In placing the guide in position, the spring catch becomes self-acting. These operations require but one hand, leaving the other free to place the safety-stop arm in position. The safety-stop is an oblong block having an angular face against which the arm of the sector in the lock may engage when the locks are moved forward by the crank. It is held in position by two links which are moved by an arm that is pinned fast to a shaft passing through the rear case, to the outer end of which is pinned the stop-arm. This arm is constructed in the form of a hand crank, having a stop-spindle placed in its handle, behind the shoulder



Gardner Gun-carriage and Limber.

of which is placed a spiral spring that forces the spindle out from the arm into the stop holes, two in number, in the rear case. When the stop-spindle is in the upper hole, the *arm* is in *line* with barrels, the safety-stop is thrown within reach of the sector-arm by which the mainsprings are compressed, and the gun is in firing position. When the spindle is in the lower hole the stop is carried forward out of the way of the sector-arm, and in no case can the springs be compressed while the safety-stop arm is down.

The carriage of the gun is of new design and construction, and is made entirely of steel and bronze. The frame for the carriage, including the side walls, bed-plate, and axle-support, is made in one casting. The lunette body and ring, the handspike ring and socket, and ground-recoil stop-support are also in one casting. The top and side trail-plates are supported at their upper corners by angle-irons, to which they are riveted. These angle-irons extend from the frame to the body and are riveted to them. Lost motion is prevented in the wheels on the arms of the axles by conical sleeves sliding into the boxes of the wheels (their ends being cupped to receive the same) against conical washers supported by linch-pins. The sleeves are forced outward by a toggle-joint actuated by a hand-lever (underneath the trail), and can be locked either in or out. Ample compensation is made for wear of surfaces by right- and left-hand screws locked by jam-nuts. The circular bed-plate of the carriage, that supports the swivel-plate of the mount, is provided with a taper socket to receive the spindle of the swivel-plate, which has a circular groove into which is inserted, by means of a lever, a sliding-bolt for holding down the swivel-plate which passes over and around the bed-plate, and may be secured to it in any desired position by the grip ring, which is fastened in such a manner that it has no movement up or down, while it has ample room to move outward, after being released by the grip-ring screw-handle, and the mount then has full range of the horizon. The base of the mount slips over and around the swivel-plate, and is held from uprising by the nut and the lock-pin on a round bolt that passes through the spindle of the swivel-plate. On the upper face of the swivel-plate is a segmental T groove to receive the head of a clamp-bolt that projects upward through the front of the base-plate. A handle-nut clamps the parts fast when the oscillator is not in use. The amplitude of oscillation is twenty degrees, and can be decreased at will by turning the oscillator stop-screw on the upper face of the base. From the base-plate project upwards two walls, forming the outer portion of a joint in which rest the walls of the mount-body. On the inner side of the body are two circular beveled friction-plates, the outer surfaces of which are forced against the inner sides of the mount; these in turn are forced against the walls of the base, and that is supported by a bolt passing through the whole and secured by a washer and nut. The friction-plates are held from rotary motion by a stout pin that passes through the whole. On the friction-plates is a grip-ring, the screw of which passes underneath the rear body of the mount far enough to form a pointing-lever with its cross-handle, thus instantly performing two functions, as the hands do not leave the screw until the gun is pointed and secured, in any position from thirty degrees elevation to forty degrees depression. At the front of the mount-body extending upward is the arm for supporting the gun-casing, which is bored for attachment by an ordinary pin-hinge. The mount-body extends far enough back to receive the nut for the elevating-screw, in the upper part of



Ammunition-drawer.

which is a sliding box to receive the pin that makes connection with the rear of the casing. The caisson that accompanies the gun is of the usual United States pattern. The chest is of oak and carries eight ammunition packing-drawers, having also sufficient space for appendages and tools. The accompanying drawing represents one of the eight drawers to be carried in the limber-chest. Each drawer holds forty-five pasteboard paper-covered cartridge packing-cases, which may be made water-proof. Each case holds twenty cartridges. The total amount of ammunition carried in the caisson is 7200 rounds. The cases are packed on end, and are supported by each other in such a manner that they cannot be shaken around or upturned, and all liability of jamming bullets or shells is prevented. The drawers have on their inside walls a series of grooves equal in number to one third of the paper cases to be packed. A movable partition (that can be withdrawn by one motion of the hand) is arranged to fit the grooves. After the drawer has received its full amount of cases, the movable partition is inserted into the grooves at the end of the drawer, thereby forming an inner wall, supporting and locking the cases firmly in position. In order to break bulk, the partition is removed, thus leaving space enough to admit the fingers to break out the first case, after which there can be no difficulty. When a portion of the cases have been removed from the drawer, it is *absolutely* necessary to secure those remaining, and the movable partition can be inserted into the grooves nearest the cases, thus securing them, even to the *last case*, as firmly as though the bulk had not been broken. The partition is secured to the drawer by a stout cord, so that there is no danger whatever of its becoming lost. See *Machine-gun*.

GARDNER MAGAZINE-GUN.—In this arm the barrel and tip-stock slide forward and backward on ways connected with the butt-stock. They are released to move forward, and secured when back by a hook into which the forward end of the trigger-guard is formed. This guard revolves, to a sufficient extent for this purpose, on a pin passing through it, at the forward end of the guard-bow. It locks the piece automatically, when it is closed, by the action of a spring at its rearmost end. In moving out the barrel the hammer is cocked by an internal connection between the barrel and the tumbler. A cartridge having been expelled backward from the magazine by the action of the magazine-spring, it is raised by the striking of a projection on the lower end of the barrel against the forward end of a bent lever, the rearmost end of which lies beneath the cartridge. This passes it up a pair of guides on the face of the frame, so shaped as to hold within their jaws the head of the cartridge by the rim. When it arrives opposite to the mouth of the chamber it is passed into it by closing the piece. By repeating the movements as described, the succeeding cartridge will pass up the guides as before, and striking from below the empty one just fired, will throw it up the guides with sufficient force to send it clear of the gun. The magazine is charged through the trough into which the space between the ways is formed. The issue of the cartridges from the magazine is limited to one at each forward motion of the barrel by the interposition of a spring stop, which is pressed out of the way by the barrel at the end of its stroke. The magazine can be cut off and held in reserve by a revolving eccentric stop, moved by a thumb-piece on the outside. The arm can then be used as a single-loader by inserting the rim of the cartridges into the guides at each opening of the piece. By a cam-motion of the movable trigger-guard power is obtained to start the barrel slightly away from the butt, and thus to overcome the chief obstacle to the removal of the empty shell, viz., its sticking at the start.

GARLAND.—A variety of chaplet made of flowers, feathers, and sometimes of precious stones, worn on the head in the manner of a crown. Both in ancient and modern times it has been customary to present garlands of flowers to warriors who have distinguished themselves. A beautiful young woman was generally selected for that purpose.

GARNISHED.—A term in Heraldry. Any charge is said to be *garnished* with the ornaments set on it.

GARNISH-NAILS.—Diamond-headed nails, in early times used to ornament artillery-carriages.

GARRET.—A term formerly and commonly used to signify a turret or battlement. It is now obsolete.

GARRISON.—A body of troops stationed in or near a fort or fortified town to defend it, or to keep the inhabitants in subjection. The garrison of a work, when it is practicable, should always be a complete organization, or composed of detachments belonging to the same unit of force. Garrisons should not live within field-works unless there is a pressing necessity for this to be done. As a rule, they should encamp near the works they are to defend, and only keep guards within the works. Nevertheless the engineer or other officer who lays out a field-work should always consider the possibility of its being occupied by a garrison, and should provide the necessary accommodations, so far as interior space may be required. The proportion of men given for the protection of a garrison generally has for its object both the number required for the immediate security of the place and that required to sustain a siege; an arrangement which in peace avoids the necessity of shutting up a considerable body of troops without an immediate object. See *Post*.

GARRISON COURT-MARTIAL.—A legal tribunal for the examination and punishment of all offenders against martial law, or against good order and military discipline.

The following is a form of record for a Garrison Court-Martial:

GARRISON COURTS-MARTIAL.
First Day.

Proceedings of a Garrison Court-Martial held at Fort ——, ——, pursuant to the following order:

HEADQUARTERS FORT ——, ——,
——, 187 .

Post Orders }
No. —. }

A Garrison Court-Martial will convene at this Post on the —— ——, 187 , at 10 o'clock A.M., or as soon thereafter as practicable, for the trial of such prisoners as may properly be brought before it.

Detail for the Court.

First Lieutenant A. B., —— Artillery.
First Lieutenant C. D., —— Artillery.
Second Lieutenant E. F., —— Artillery.
Second Lieutenant G. H., —— Infantry, J. A.

By command of —— ——:

(Signed) —— ——,
1st *Lieutenant* —— *Artillery*,
Post Adjutant.

FORT ——, ——,
——, 187 .

The Court met, pursuant to the foregoing order, at —— o'clock A.M.

Present:

First Lieutenant —— ——, —— Artillery.
First Lieutenant —— ——, —— Artillery.
Second Lieutenant —— ——, —— Artillery.
Second Lieutenant —— ——, —— Infantry, J. A.

The Court then proceeded to the trial of Private —— ——, Battery ——, —— Regiment U. S. Artillery, who was then brought before the Court, and having thereupon heard the order convening it read, was asked if he had any objection to being tried by any member named therein, to which he replied in the negative. The Court, including the Recorder, was then duly sworn according to law in the presence of the prisoner.

The mode of swearing a Regimental or a Garrison Court is as follows:

The junior member of the Court is its Recorder, and administers to the other two members the oath prescribed in the article for members, after which the Presiding Officer administers to the Recorder the following oath, which combines with the oath of a member the additional obligation required of the Judge Advocate, or person officiating as such:

"You, A—— B——, do swear that you will well and truly try and determine, according to evidence, the matter now before you, between the United States of America and the prisoner to be tried, and that you will duly administer justice, according to the provisions of 'An Act establishing rules and articles for the government of the armies of the United States,' without partiality, favor, or affection; and if any doubt should arise, not explained by said articles, according to your conscience, the best of your understanding, and the custom of war in like cases; and you do further swear that you will not divulge the sentence of the Court to any but the proper authority, until it shall be duly disclosed by the same; neither will you disclose or discover the vote or opinion of any particular member of the Court-Martial, unless required to give evidence thereof, as a witness, by a Court of Justice, in a due course of law. So help you God."

The record from here on is made up in the same general manner as indicated for the proceedings of General Courts-Martial. The junior member, as Recorder or Clerk to the Court-Martial, should, with the President, authenticate its proceedings in each and every case.

In the absence of a Judge Advocate, or person officiating as such, as a prosecuting attorney for the United States, with *legal* obligations to the prisoner—confined, however, simply to objecting to any leading or criminating question—the Court itself proceeds with the business referred to it, summons all necessary witnesses, and asks all questions tending to elucidate the matter, pro and con, without denial to the prisoner of his right to ask any additional question pertinent to the issue, or to make any statement *respectful* in its character.

Equal obligation rests on each member of the Court to well and truly try and determine, according to evidence, the matter before it, and to duly administer justice.

Questions by the Recorder, or any other member, if not objected to, become "*Questions by the Court.*"

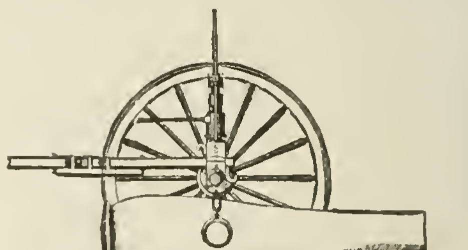
The "decision and orders" of the Reviewing Officer, confirming, disapproving, or remitting the sentence, should follow immediately after the signature of the President and Recorder, and be signed *by him*, and not by his command, and then forwarded, without delay, together with a copy of his Post or Regimental Order promulgating the proceedings, to Department Headquarters, for the supervision of the Department Commander. See *Courts-Martial.*

GARRISON DES JANISSARIES.—The *élite* or flower of the Janissaries of Constantinople was frequently sent into garrison on the frontiers of Turkey, or to the places where the loyalty of the inhabitants was doubted. The Janissaries did not indeed assist in the immediate defense of a besieged town or fortress, but they watched the motions of all suspected persons, and were subject to the orders of their officers, who usually commanded the garrison.

GARRISON-FLAG.—In the United States service, the garrison-flag is the national flag. It is made of bunting, thirty-six feet fly and twenty feet hoist, in thirteen horizontal stripes of equal breadth, alternately red and white, beginning with the red. In the upper quarter, next the staff, is the Union, composed of a number of white stars, equal to the number of States, on a blue field, one third the length of the flag, extending to the lower edge of the fourth red stripe from the top. This flag is furnished only to very important posts, or those having large garrisons, and is hoisted only on gala-days and great occasions. See *Flags.*

GARRISON-GIN.—The largest size of gin. It is strongly built and used for raising heavy ordnance, driving piles, etc., and consists of three poles, each from 12 to 15 feet long, and 5 inches in diameter at the lower end, tapering to 3½ inches at the upper. The poles are united at the top, either by an iron ring which passes through them or by a rope which is twisted several times around each, and to this "joint" a pulley is fixed. Two of these poles are kept at an invariable distance by means of an iron rod, in order that they may support the windlass which is attached to them, its pivots running in iron cheeks fixed to the poles. When the machine is to be used, it is set up over the weight to be raised; two blocks arranged according to the Second System of Pulleys are fixed, the one to the top of the poles, the other to the weight; and the rope, after passing around both blocks, and over the pulley before mentioned, is attached to the windlass, by the revolution of which the weight can then be raised. See *Gin.*

GARRISON SLING-CART.—A form of sling-cart for moving very heavy weights. It is attached by its pole to a siege- or field-limber, and may be drawn by horses. With this cart the weight is raised by first

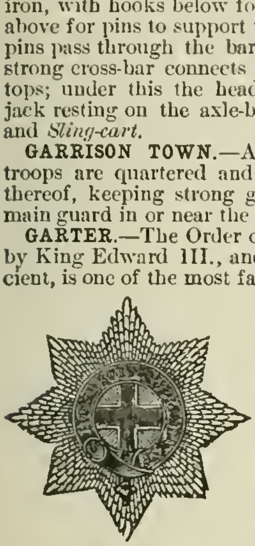


attaching to it a sling, and then applying to the sling the hooks forming the lower part of a powerful screw passing up through the axle of the cart. Above the axle is the nut of the screw, provided with long handles. Power is applied to these handles, and the screw is run up, thus raising the weight.

This sling-cart is capable of carrying 20,000 pounds; but with such heavy weights the handles of the screw are difficult to turn. To overcome this difficulty a modification has been made in the cart by substituting for the screw a hydraulic jack. Through the axle-body two vertical mortises are cut, each at a distance of twenty inches from the middle of the axle-body. Through these mortises slide two stout bars of iron, with hooks below for the sling-chain, and holes above for pins to support them as they are raised; the pins pass through the bars above the axle-body. A strong cross-bar connects the upright bars near their tops; under this the head of the jack is applied, the jack resting on the axle-body. See *Hand Sling-cart* and *Sling-cart.*

GARRISON TOWN.—A strong locality in which troops are quartered and do duty for the security thereof, keeping strong guards at each post, and a main guard in or near the market-place.

GARTER.—The Order of the Garter was instituted by King Edward III., and though not the most ancient, is one of the most famous of the military orders of Europe. Selden says that it "exceeds in majesty, honor, and fame all chivalrous orders in the world." It is said to have been devised for the purpose of attracting to the king's party such soldiers of fortune as might be likely to aid in asserting the claim which he was then making to the crown of France, and intended as an imitation of King Arthur's round table. The round table was erected at Windsor, and the knights and nobles who were invited from all parts of the world were exercised at tilts and tournaments as a preparation for the magnificent feasts that were spread before them. That general "jousts and tournaments" of this description were held at Windsor is assured from the letters summoning them bearing date January 1, 1344, and quoted by Sir Harris Nicolas in his *Orders of Knighthood,* and also from the narrative of Froissart, who connects them with the institution of the order. The original number of the Knights of the Garter was twenty-five, his Majesty himself making the twenty-sixth. The story that the Countess of Salisbury let fall her garter when dancing with the King, and that the King picked it up and tied it round his own leg, but that, observing the jealous glances of the Queen, he restored it to its fair owner with the exclamation, *Honi soit qui mal y pense,* is about as well authenticated as most tales of the kind, and has, moreover, in its favor that it accounts for the otherwise unaccountable emblem and motto of the order. Sir Harris Nicolas, whose error does not usually lie in the direction of credulity, says that though the writers on the order have treated it with contempt, they have neither succeeded in showing its absurdity nor suggested any more probable theory. Various dates are assigned to the Order of the Garter. Froissart, as above mentioned, gives 1344, and fixes on St. George's Day (April 23), 1344; but Stow, and, it is said, the statutes of the order, fix it six years later, viz., 1350. The original statutes have long since perished, and little reliance can be placed on the modern copies of them, and nothing is known on the subject with precision till the compilation of the *Black Book* in the latter part of the reign of Henry VIII. In these circumstances Sir Harris Nicolas is of opinion that, though founded at the former period, it was not till the latter that the order was finally organized and the Companions chosen. It was founded in honor of the Holy Trinity, the Virgin Mary, St. Edward the Confessor, and St. George; but the last, who had become the tutelary saint of England, was considered its special patron; and for this reason it has always born the title of "The Order of St. George," as well as of "The Garter." A list of the original Knights, or Knights-founders, is given by Sir Harris Nicolas. The well known emblem of the order is a dark blue ribbon edged with gold, bearin the motto *Honi soit qui mal y pense,* in gold letters, with a buckle and pendant of gold richly chased. It is worn on the left leg below the knee. The mantle is of blue velvet lined with white taffeta, and on the left breast a star is embroidered. The hood and surcoat are of crimson velvet lined with white taffeta. The hat is of black velvet, with a plume of white ostrich-feathers, in the center of which there is a tuft of black herons' feathers, all fastened to the hat by a band of diamonds. The collar is of gold, and consists of twenty-six pieces, each in the form of a garter. The "George" is the figure of St. George on horseback encountering the Dragon, and is worn hanging from the collar; there is a "lesser George" pendent to a broad dark blue ribbon over the left shoulder. The star, which is of eight points, is silver, and has upon the center the cross of St. George, gules, encircled with the garter. The officers of the order are—the Prelate (the Bishop of Winchester), the Chancellor (the Bishop of Oxford), the Registrar, (the Dean of Windsor), the Garter King of Arms, and the Usher of the Black Rod.



Star of the Order of the Garter.

GARTER KING OF ARMS.—The Garter King of Arms is also the principal King of Arms in England. Though held by the same person, they are distinct offices. The first was instituted for the service of the Order of the Garter, not on its first foundation, but afterwards by Henry V. as Sovereign, with the advice and consent of the Knights-companions. The peculiar duty of Garter King of Arms is to attend upon the Knights at their solemnities, to intimate their election to those who are chosen by the order, to call them to be installed at Windsor, to cause their arms to be hung up over their stalls, and to marshal their funeral processions, and those of royal personages, and of members of the higher nobility. In the capacity of Principal King of Arms, he grants and confirms arms, under the authority of the Earl Marshal, to whom he is not subject as Garter King of Arms. All new grants or patents of arms in England are first signed and sealed by Garter King of Arms, and then by the king of the province to which the applicant belongs. See *Garter.*

GAS.—The term gas was employed by the older chemists to designate any kind of air or vapor. Van Helmont was the first chemist who limited the term gas to such elastic fluids as had not been rendered liquid or solid by the reduction of temperature. In common language some distinction is made between gases and vapors. Gases are understood to be invariably aëriform at ordinary temperatures and atmospheric pressures, while vapors under these conditions are solid or liquid, and only assume a vaporous or apparently gaseous form at relatively high temperatures. Thus oxygen, hydrogen, nitrogen, chlorine, etc., are considered true gases; while water, sulphur, iodine, etc., when heated to certain definite points, become transformed into vapors. There is, however, no distinction between gases and vapors in a theoretic point of view. The *kinetic theory of gases,* first put forth by Daniel Bernouilli, is to the effect that they are formed of material particles, free in space, and actuated by very rapid rectilinear movements, and that the tension of elastic fluids results from the shock of their particles against the sides of the containing vessels. This theory has been recently revived and developed chiefly by Clausius and Clerk Maxwell. Their perfect elasticity is one of the most important physical peculiarities of gases. Within the limits of all ordinary experiments it is generally true that "the volume of a gaseous body is inversely as the compressing force." In consequence of their extreme elasticity, gases exhibit an entire absence of cohesion among their particles, and in this respect they differ essentially from liquids. A vessel may be filled either partially or completely with a liquid, and this liquid will have a definite level surface or limit. With gases it is otherwise; they always perfectly fill the vessel that contains them, however irregular its form. Instead of cohesion, there is a mutual repulsion among their particles, which have a continual tendency to recede further from each other, and thus exert a pressure in an outward direction upon the sides of the vessel in which the gas is inclosed. This outward pressure is greater or less according as the elasticity of the gas is increased or diminished. Dalton long ago remarked that "there can scarcely be a doubt entertained respecting the reducibility of all elastic fluids, of whatever kind, into liquids; and we ought not to despair of effecting it at low temperatures and by strong pressure exerted upon the unmixed gases." This prediction has been completely fulfilled. It occurred to Faraday, who led the van in these investigations, that the most probable mode of obtaining gases (or rather what, under ordinary circumstances, would be gases) in the liquid state, would be to generate them under strong pressure. When thus produced in strong bent glass tubes, they continued liquid at low temperatures while the pressure was maintained; but on removing the pressure (breaking the tube), they instantly passed into the gaseous state. In his Memoir published in the *Philosophical Transactions* for 1823 he announced that he had succeeded in liquefying chlorine, euchlorine, sulphuretted hydrogen, nitrous oxide, cyanogen, ammonia, and hydrochloric, sulphurous, and carbonic acids. Subsequently, under the joint action of powerful mechanical pressure and extreme cold, the number of liquefiable gases was so far extended as to include all except oxygen, hydrogen, nitrogen, nitric oxide, and coal-gas; and all the following gases were obtained in a solid form: hydriodic acid, hydrobromic acid, sulphurous acid, sulphuretted hydrogen, carbonic acid, cyanogen, ammonia, euchlorine, fluoride of silicon. The researches of Andrews established the fact that for every gas there is a certain minimum temperature at which the energy of the molecular movement is exactly balanced by the force of cohesion, *whatever be the pressure to which the vapor is subjected;* this temperature is the "critical point" of the gas. It was because the critical points of certain gases are very low that they so long resisted all efforts to condense them. No amount of pressure without the necessary cold could be effectual. At last, in the end of 1877, by the use of powerful apparatus and ingenious contrivances for producing cold, the difficulties have been overcome by MM. Cailletet and Raoul Pictet of Geneva. By combining a cold of 120° to 140° below zero, with enormous pressures of 550 and even 650 atmospheres, M. Pictet was able to liquefy oxygen. "He has also liquefied and even solidified hydrogen, which he has seen to issue from the tube in the form of a steel-blue liquid jet, which partly solidified. The solid hydrogen, in falling on the floor, produced the shrill noise of a metallic hail, thus confirming the bold and ingenious idea of Faraday, who first suggested that hydrogen is a metal." The distinction between permanent and condensable gases is thus abolished.

Graham's experiments with the simple diffusion-tube show that the diffusiveness or *diffusion volume* of a gas is in the inverse ratio of the square root of its density; consequently the squares of the times of equal diffusion of the different gases are in the ratio of their specific gravities. Thus, the density of air being taken as the standard of comparison at 1, the square root of that density is 1, and its diffusion volume is also 1; the density of hydrogen is 0.0692, the square root of that density is 0.2632, and its diffusion volume is $\frac{1}{0.2632}$, or 3.7994; or, as actual experiment shows, 3.83—that is to say, if hydrogen and common air be placed under circumstances favoring their mutual diffusion, 3.83 volumes of hydrogen will change place with 1.00 of air. The following table gives: 1. The density; 2. The square root of the density; 3. The calculated, and 4. The observed velocity of diffusion or diffusiveness of several important gases; the numbers in the last column, headed "Rate of effusion," being the results obtained by experiment upon the rapidity with which the different gases escape into a vacuum through a minute aperture about $\frac{1}{500}$ of an inch in diameter.

Gas.	Density.	Square root of density.	Calculated velocity of diffusion.	Observed velocity of diffusion. Air = 1.	Rate of effusion.
Hydrogen	0.06926	0 2632	3.7994	3.83	3.613
Light carburetted hydrogen	0.559	0.7476	1.3375	1.344	1.322
Carbonic oxide	0.9678	0.9837	1.0165	1.0149	1.0123
Nitrogen	0.9713	0.9859	1.0147	1.0143	1.0164
Olefiant gas	0.978	0.9889	1.0112	1.0191	1.0128
Binoxide of nitrogen	1.039	1.0196	0.9808	......	......
Oxygen	1.1056	1.0515	0.9510	0.9487	0.950
Sulphuretted hydrogen	1.1912	1.0914	0.9162	0.95	......
Protoxide of nitrogen	1.527	1.2357	0.8092	0.82	0.834
Carbonic acid	1.52901	1.2365	0.8087	0.812	0.821
Sulphurous acid	2.247	1.4991	0.6671	0.68	......

The process of diffusion is one which is continually performing an important part in the atmosphere around us. Accumulations of gases which are unfit for the support of animal and vegetable life are by its means silently and speedily dispersed, and this process thereby contributes largely to maintain that uniformity in the composition of the aërial ocean which is so essential to the comfort and health of the animal creation. Respiration itself, but for the process of diffusion, would fail of its appointed end, in rapidly renewing to the lungs a fresh supply of air, in place of that which has been rendered unfit for the support of life by the chemical changes which it has undergone. A reference to the last two columns of the above table shows that, within the limits of experimental errors, the rate of effusion of each gas coincides with its rate of diffusion. Graham's experiments show that the velocity of *transpiration* (the term which that chemist applied to the passage of gas through long capillary tubes) is entirely independent of the rate of diffusion, or of any other known property. It varies with the chemical nature of the gas, and is most probably "the resultant of a kind of elasticity depending upon the absolute quantity of heat, latent as well as sensible, which different gases contain under the same volume; and therefore will be found to be connected more immediately with the specific heat than with any other property of gases." Oxygen is found to have the lowest rate of transpiration. Taking its transpiration velocity at 1, that of air is 1.1074; of nitrogen, 1.141; of carbonic acid, 1.369; of sulphuretted hydrogen, 1.614; of ammonia, 1.935; of olefiant gas, 1.980; and of hydrogen, 2.288. In the passage of gases through diaphragms, the law of the diffusion of gases is more or less disturbed or modified according to the force of adhesion in the material of which the diaphragm is composed; the disturbance being the greatest in the case of soluble gases and a moist thin diaphragm, such as a bladder or a rabbit's stomach.

All gases are more or less soluble in water and other liquids. Some gases, as, for example, hydrochloric acid and ammonia, are absorbed by water very rapidly, and to a great extent, the liquid taking up 400 or 600 times its bulk of the gas; in other cases, as carbonic acid, water takes up its own volume of the gas; whilst in the case of nitrogen, oxygen, and hydrogen it does not take up more than from $\frac{1}{25}$ to $\frac{1}{50}$ of its bulk. As the elasticity of the gas is the power which is here opposed to adhesion, and which at length limits the quantity dissolved, it is found that the solubility of each gas is greater, the lower the temperature, and the greater the pressure exerted upon the surface of the liquid. Dr. Henry found that at any given temperature the *volume* of any gas which was absorbed was uniform, whatever might be the pressure; consequently that the *weight* of any given gas absorbed by a given volume of any liquid at a fixed temperature increased directly with the pressure. If the pressure be uniform, the quantity of any given gas absorbed by a given liquid is also uniform for each temperature; and the numerical expression of the solubility of each gas in such liquids is termed its *coefficient of absorption* or *of solubility*, at the particular temperature and pressure, the volume of the gas absorbed being in all cases calculated for 32° Fahr., under a pressure of 29.92 inches of mercury. Thus, one volume of water at 32°, and under a pressure of 29.92 inches of the barometer, dissolves 0.04114 of its volume of oxygen; and this fraction represents the coefficient of absorption of oxygen at that temperature and pressure. Similarly, the coefficient of absorption of common air is 0.02471. In consequence of this solubility of the air, all water contains a certain small proportion of it in solution; and if placed in a vessel under the air-pump, so as to remove the atmospheric pressure from its surface, the dissolved gases rise in minute bubbles. Small as is the quantity of oxygen thus taken up by water from the atmosphere, it is the means of maintaining the life of all aquatic animals. If the air be expelled from water by boiling, and it be covered with a layer of oil, to prevent it from again absorbing air, fish or any aquatic animals placed in such water quickly perish. Even the life of the superior animals is dependent upon the solubility of oxygen in the fluid which moistens the air-tubes of the lungs, in consequence of which this gas is absorbed into the mass of the blood, and circulation through the pulmonary vessels.

The following table, drawn up from the researches of Bunsen and Carius, shows the solubility of some of the most important gases, both in water and in alcohol.

Each of these gases, with the exception of hydrochloric acid, may be expelled from the water by long-continued boiling. Gases are not absorbed by all liquids in the same order; for example, naphtha absorbs most olefiant gas, oil of lavender most protoxide of nitrogen, olive-oil most carbonic acid, and solution of chloride of potassium the most carbonic oxide. If a mixture of two or more gases be agitated with water, or probably any other liquid, a portion of each gas will be absorbed, and the amount of each so absorbed or dissolved will be proportional to the relative volume of each gas multiplied with its coefficient of solubility at the observed temperature and pressure. As all ordinary liquids exert a greater or less solvent action on gases, a gas to be examined quantitatively should be collected over mercury.

The adhesion of gases to solids next requires a notice. Illustrations of this phenomenon perpetually occur. Thus, wood and other solid substances immersed in water or other liquids appear covered with air-bubbles. It is this adhesion of air to the surface of glass tubes which causes the difficulty of obtaining barometers and thermometers completely free from air. It is in consequence of the adhesion of air to their surfaces that many small insects are enabled to skim lightly over the surface of water which does not wet them. A simple method of illustrating this phenomenon is by gently dusting iron filings over the surface of a vessel of water; if we proceed carefully, a considerable mass of the iron may accumulate upon the surface; till at last it falls in large flakes, carrying down with it numerous bubbles of air. As the particles of iron are nearly eight times as heavy as water, it was only the adherent air that enabled them to float upon the surface. Closely allied to this adhesion is that remarkable property of condensation which porous bodies, and especially charcoal, exert over gases. Owing to this property of charcoal—especially freshly burned vegetable charcoal—various gases may be separated from their watery solution by filtration of the latter through it; for an example, sulphuretted hydrogen may be removed from water so completely that it cannot be detected either by its well-known odor or by the ordinary tests. Saussure found that 1 volume of freshly burned box-wood charcoal absorbed 90 volumes of ammonia, 85 of hydrochloric acid, 65 of sulphurous acid, 55 of sulphuretted hydrogen, 40 of protoxide of nitrogen, 35 of carbonic acid, 35 of bicarburetted hydrogen, 9.4 of carbonic oxide, 9.2 of oxygen, 7.5 of nitrogen, 5.0 of carburetted hydrogen, and 1.7 of hydrogen. These results follow an order very nearly the same as that of the solubility of the gases in water. Stenhouse has investigated the differences in the absorbent power of the different kinds of charcoal; the table on page 746 shows his most important results: .5 of a gram of each kind of charcoal being employed, and the numbers in the table indicating in cubic centimeters the quantity of absorbed gas.

Gas.	Volume of each gas dissolved in one volume of water.		Volume of each gas dissolved in one volume of alcohol.	
	At 32 degrees F.	At 59 degrees F.	At 32 degrees F.	At 59 degrees F.
Ammonia	1049.69	727.2	......	......
Hydrochloric acid	505.9	458.0	......	......
Sulphurous acid	68.861	43.564	328.62	145.55
Sulphuretted hydrogen	4.3706	3.2326	17.181	9.539
Chlorine	Solid.	2.368	.....	....
Carbonic acid	1.7967	1.002	4.3295	3.1993
Protoxide of nitrogen	1.3052	0.0778	4.1780	3.2678
Olefiant gas	0.2563	0.1615	3.5950	2.8825
Binoxide of nitrogen	......	......	0.31606	0.27478
Marsh gas	0.05449	0.03909	0.52259	0.48280
Carbonic oxide	0.03287	0.02432	0.20443	0.20443
Oxygen	0.04114	0.02989	0.28397	0.28397
Nitrogen	0.02035	0.01478	0.12634	0.12142
Air	0.02471	0.01795	......	....
Hydrogen	0.01930	0.01930	0.06925	0.06725

Gas used.	Kind of Charcoal employed.		
	Wood.	Peat.	Animal.
Ammonia	98.5	96.0	43.5
Hydrochloric acid	45.0	60.0	....
Sulphurous acid	32.5	27.5	17.5
Sulphuretted hydrogen	30 0	28.5	9.0
Carbonic acid	14 0	10.0	5.0
Oxygen	0.8	0.6	0.5

So rapid is this action of charcoal, that Stenhouse has proposed to use a respirator filled with it to protect the mouth and nostrils in an infected atmosphere; and the employment of trays of powdered wood-charcoal in dissecting-rooms, in the wards of hospitals, and in situations where putrescent animal matter is present, is found to act very beneficially in purifying the air by absorbing the offensive gases. Its use in reference to the filtration of water has been already allnded to. The determination of the exact specific gravity of the different gases is of great importance in calculating the proportions of the different ingredients of compounds into which they enter; and the whole series of numbers expressing the chemical equivalents or atomic weights of bodies depend upon the accuracy of the determination of the specific gravity of hydrogen and oxygen.

The following table gives the specific gravity and the weight of 100 cubic inches of some of the most important gases at a barometric pressure of 30 inches and at a temperature of 60°, together with the name of the observer:

Gas.	Specific Gravity. Air = 1.	Weight of 100 Cubic Inches in Grains.	Observer.
Air	1.0000	30 935	Regnault.
Oxygen	1.1056	34 203	"
Nitrogen	0.9713	30.119	"
Hydrogen	0.0692	2.143	"
Carbonic acid	1 5290	47.303	"
Chlorine	2.5000	76.250	Thomson.
Ammonia	0 5902	18 003	"
Carburetted hydrogen	0.5555	16 944	"
Olefiant gas	0 9722	29 652	"
Arseniuretted hydrogen	0 5290	16 130	Tromsdorff.
Sulphuretted hydrogen	1 1805	36.007	Thomson.
Cyanogen	1 8055	55 069	Gay-Lussac.
Hydrochloric acid	1.2847	39.183	Thomson.
Sulphurous acid	2.2222	67 777	"

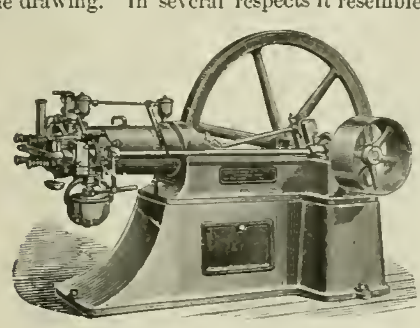
Regarding the chemical properties of gases, most of the different gases, when pure, can be readily distinguished by some well-marked physical or chemical property. Some are distinguished by their color, others by their very peculiar odor; but several of the most important ones—viz., oxygen, nitrogen, hydrogen, carbonic acid, carbonic oxide, light carburetted hydrogen, olefiant gas, and the protoxide of nitrogen—require various other means for their discrimination.

GAS CHECK.—Soon after the introduction of the Woolwich guns it became evident that a great evil had to be combated. This was that the heavy charges used, and the consequent rush of gas along the bore, especially at that portion of it immediately over the seat of the shot, seriously eroded the steel tubes of the guns. To such an extent does this erosion take place that an impression of the rear portion of the bore of a heavy Woolwich gun resembles, in its roughness, the bark of an elm-tree; and obviously this erosion shortens the lives of the guns. Gas-checks, originally introduced to prevent erosion of the bore, have been found not only to fulfill this purpose, but also to increase range and accuracy, and to be capable of giving the requisite rotation to the projectile so as to render the use of studs unnecessary. This is accomplished by bolting a flanged copper disk to the base of the shell. In the larger calibers the studs are going out of use. The projectile for the 100-ton gun receives its motion of rotation from an expanding (copper) gas-check on its base fastened by 12 screws on the base of the projectile. Under the action of the powder-gas, the check is expanded and compressed; its forward portion is compressed between the walls of the bore and the surface of the projectile, which is dentated near the base. The copper is molded to the lands and grooves exactly, giving the motion of rotation and preventing the escape of the gas. On the circumference of the gas-check are buttons which take to the grooves. These are not necessary except as a convenience in loading. They prevent the projectile from being forced down too far by the hydraulic rammer, and so crushing the powder.

In experiments with the 8-inch breech-loading rifle, both copper and steel gas-checks were used. The former proved the better gas-checks, but at times stuck to the face of the breech-block after firing, to such extent as to make it difficult to withdraw the block. With the steel gas check, however, no difficulty was found in withdrawing the block after firing, though there was at times a slight escape of gas. To remedy the defective operation of the checks constructed of a single metal (either copper or steel or other metals), a gas-check was designed and made of steel and copper combined, thus insuring in the ring the hardness and elasticity of steel at the base with the compressibility and extensibility of the copper part in contact with the walls of the gas-ring seat. This construction secures through the extensible copper a perfect and close check at the sides of the seat in the chamber of the gun, while at the same time, the check having its base of hard and unyielding steel, any binding or sticking of the breech fermeture in opening the breech is prevented. The mode of construction of an 8-inch gas-check is as follows: Two holes are punched, near either end, through a steel bar about 14 inches long, 2½ inches wide, and ½ inch thick. The bar is then slit with a chisel between these two holes, and the slit first enlarged by a mandrel, and finally formed into a circle on the anvil. It is then placed in the lathe, its bearing surface with the copper finished, and only sufficient excess of metal left elsewhere to allow subsequent slight corrections. The steel sabot is then carefully heated over a slow charcoal-fire until it attains a dull red heat, and is then immersed in a bath of rape-oil and left to cool. A 2-inch round copper bar, 14 inches long, is then similarly shaped into a ring; then placed in the lathe, its face and shoulder which bear against the steel sabot is finished, and its interior diameter roughly shaped. See *Broadwell Ring*.

GASCON—GASCONNADE.—The term *gascon* is now employed, in the French language, to denote a boaster or braggart, and *gasconnade* to signify any extravagant or absurd vaunting—the inhabitants of the district once known as Gascony having long been notorious in this respect. An example may be mentioned: A Gascon, on a visit to Paris, was asked by his city-friend what he thought of the Colonnade of the Louvre. His reply was, "Ah, it's not bad; it resembles pretty closely the back part of the stables at my father's castle!" There are in French volumes filled with the original and numerous sallies of these humorous boasters.

GAS-ENGINE.—Many attempts have been made in the arsenal to utilize as a motive power the expansive force arising from the explosion of a mixture of common coal-gas, such as is in general use for illuminating purposes, and common air. The first attempt of this kind which had any commercial success was that of Lenoir, a French inventor. It resembles in its general features an ordinary horizontal steam-engine. It has two slides, one on each side of the cylinder, which are opened and closed by eccentrics in the usual way. Through one of the slides, air and gas flow into the cylinder, in the proportions of about 11 of air to 1 of gas, until the cylinder is nearly half full, when the connection with the galvanic battery is made by the revolution of the shaft, causing a spark inside the cylinder, and consequent explosion of the mixture of air and gas. This explosion forces the piston from the middle of the cylinder to the further end. The products of the explosion then escape from the cylinder by the other slide-valve, which opens at the proper instant. The momentum which the fly-wheel has now acquired will carry the piston back to the middle of the cylinder, sucking in behind it, through openings which are made by the action of the eccentric on the slide, a fresh supply of air and gas; and when the piston has reached to the middle of the cylinder, the further inflow of air and gas is stopped by the slide closing, and at the same instant a spark of electricity is sent into the air and gas, exploding it as before. The first half of the stroke of the piston is thus employed in sucking in the requisite quantities of air and gas, and the last half of the stroke giving off the power arising from the explosion of the mixture of air and gas. Better gas-engines than Lenoir's are now in use, and one of the best is styled the Otto Silent Gas-engine, shown in the drawing. In several respects it resembles Le-



Otto Silent Gas-Engine.

noir's, but it differs from it in others. Instead of an electric spark, a small, constantly burning gas-flame is used to fire the charge. But the main difference lies in the use of a more dilute mixture of gas and air, placed under a pressure of above 30 pounds above the atmosphere, by which only a portion of the charge becomes combustible; the remainder is simply expanded, and so not only is the shock of a full explosion avoided, but there is a more sustained pressure on the piston throughout the stroke. We may compare the interior of the cylinder to that of a soda-water bottle with straight sides lengthwise, only it has no constricted portion or neck. One third of its length at the bottom end is taken up by the combustion-chamber; another third by the piston; and the remaining third, or rather more, by the space over which the piston travels. A jacket of cold water surrounds the cylinder to keep it cool. There are two openings in the combustion-chamber—one for the admission of the charge, and the other for the escape of the products of combustion. Attached to the combustion-chamber there is a slide-valve whose movements are so arranged that it first admits the air and gas in due proportions, which the return of the piston compresses, and then another movement of the valve fires the mixture by exposing it to the gas-flame. The explosion, so to call it, occurs once in two revolutions when the engine is fully loaded, but less often when it is not. In the Otto it acts on the piston at the beginning, not as in the Lenoir at the middle of the stroke; but the piston is connected in a very similar way with the fly-wheel in both engines. The cost for the gas is about one penny per hour per horse-power.

GAS-ESCAPE.—Rifled muzzle-loading built-up and converted guns are provided with small channels called *gas-escapes*, through which smoke issues on firing, if the inner tube is cracked through, thus giving warning that it is time to cease firing.

GASKET.—In artillery, a flat plaited cord used for "stoppering the fall." It may also be made (on the same principle as the *selvagee*) by placing the same number of rope-yarns in a straight line and marling down.

GAS-RING.—A thin plate of steel or copper, perforated to the exact size of the caliber of the gun, and used as a face-plate to the breech-block in Sharp's breech-loading rifle and Broadwell's breech-loading ordnance. It is used by the Prussian Government. The breech-block is chambered out larger than the hole in the plate, so that the gas from the explosion of a charge in the gun flies back into the chamber and presses the plate or ring well forward against the breech of the gun.

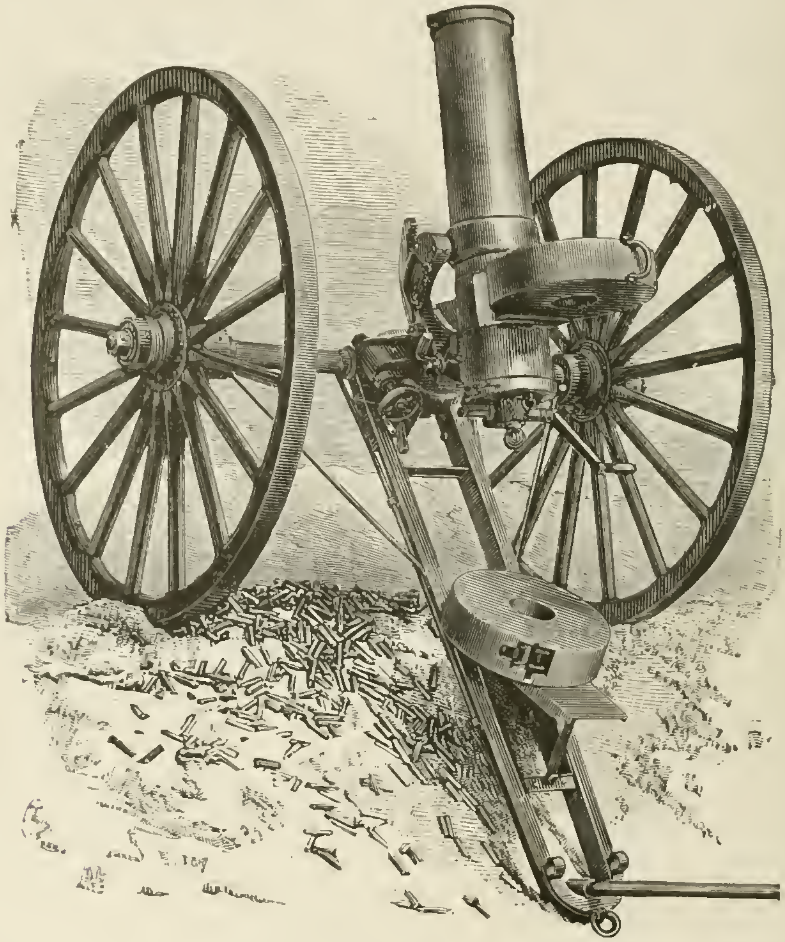
GASTRAFETES.—A very ancient variety of cross-bow, so called because the crossbow-man used to rest it on his stomach.

GATE.—A door of strong planks with iron bars to oppose an enemy. Gates are generally fixed in the middle of the curtain, from whence they are seen and defended from the two flanks of the bastions. The gate, being a most important point in all fortified places, is usually protected by various devices. It is flanked by towers with loopholes, from which assailants may be attacked, and is frequently overhung by a machicolated battlement, from which missiles of every description were poured upon the besiegers. City gates, and gates of large castles, have in all ages been the subjects of great care in construction; and when from some cause, such as the cessation of constant fighting, or a change in the mode of warfare, gateways have lost their importance in a military point of view, they have maintained their position as important architectural works, and where no longer useful have become ornamental. In very ancient times we read of the "gate" as the most prominent part of a city, where proclamations were made, and where the kings administered justice. The Greek and Roman gates were frequently of great magnificence. The propylæa at Athens is a beautiful example, and the triumphal arches of the Romans are the ornamental offspring of their city gates. Most of the towns in England have lost their walls and city gates; but a few, such as York and Chester, still retain them, and give an idea of the buildings which formerly existed, but which now remain only in the name of the streets where they once stood. English castles retain more of their ancient gates, and from these we may imagine the frowning aspect every town presented during the Middle Ages. Abbeys, colleges, and every class of buildings were shut in and defended by similar barriers; many of these still exist in Oxford and Cambridge, and the abbey gates of Canterbury and Bury St. Edmunds are well-known specimens of monastic gateways.

GATEWAY.—In works with large garrisons, where the means of frequent communication with the exterior are requisite, posterns of ordinary dimensions are found not to afford a sufficient convenience for the daily wants. In such cases a passage-way of sufficient width to admit of at least a single carriage-road with narrow foot paths on each side has to be opened through the rampart, which, whenever it is practicable to do so, should be arched and covered with earth to render it bomb-proof. The passage-way should for security have the bottom of its outlet at least twelve feet above the bottom of the enceinte ditch; and when this difference of level cannot be obtained the main ditch should be deepened sufficiently for the purpose below the outlet. A gateway of sufficient height and width for the passage of the ordinary vehicles for the service of the garrison is made through the scarp-wall. This gateway is arched at top, where a machicoulis defense may also be arranged to guard the outlet on the exterior. See *Communications* and *Gate*.

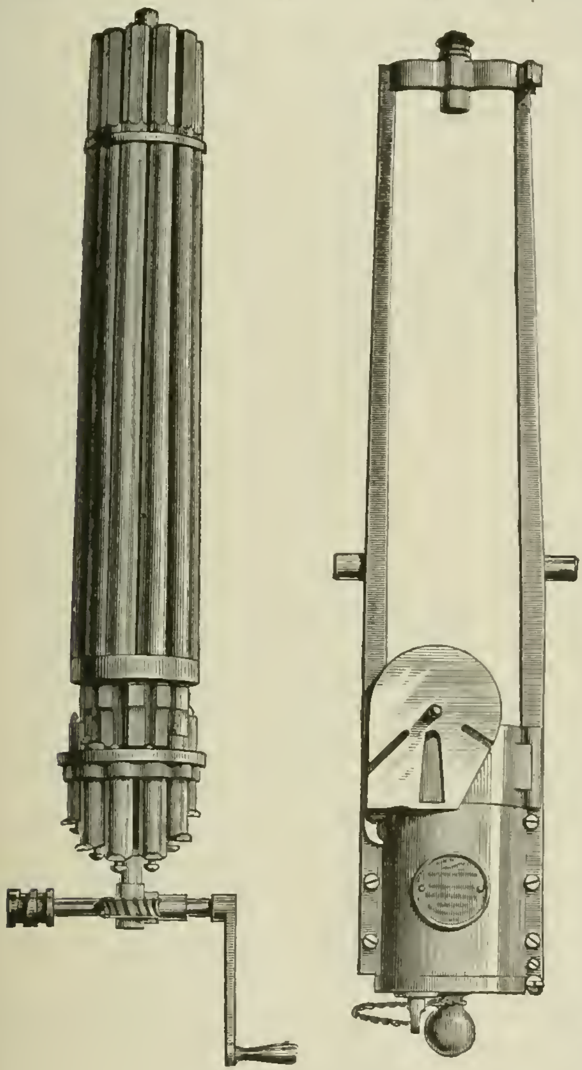
GATLING GUN.—Among the many important and valuable inventions in fire-arms, of which the present century has been prolific, there is none that equals the Gatling gun in originality of design, rapidity of fire, and effectiveness. The severest tests and trials, and its practical use in warfare, have indisputably established its high reputation as a most formidable death-dealing weapon. Trials of the gun have been made from its invention to the present day by the military authorities of the United States, by Mexico, by every Nation of Europe (except the Greeks and Belgians), by several of the South American States, by Egypt, and by China and Japan. These trials have made the gun well known, and its position as an important part of the armament of modern armies is now well assured. Besides, the gun has been formally adopted as an auxiliary service-arm in many of the countries mentioned. The gun was first introduced to European Governments in 1867. At this time the manufacture of metallic cartridges was in its infancy, and the ammunition furnished for the gun was necessarily imperfect. With this imperfect ammunition and with guns that had not the important improvements made during the last few years, the early trials were conducted. The new-model gun and the cartridges recently improved work perfectly, and commend themselves to the critical examination and highest consideration of Governments. The accompanying drawing represents the improved Gatling gun and feed-magazine. This new feed is positive in its action, and by it the gun can be fired, at the rate of 1200 shots per minute, at *all* degrees of elevation and depression. These results have never been attained by any other fire-arm, and will be noticed in detail farther on.

The gun consists of a number of very simple breech-loading rifled barrels grouped around and revolving about one shaft to which they are parallel. These barrels are loaded and fired while revolving, the empty cartridge-shells being ejected in continuous succession. Each barrel is fired only once in a revolution, but as many shots are delivered during that time as there are barrels, so that the ten-barrel Gatling gun fires ten times in one revolution of the group of barrels. The action of each part is therefore deliberate, while collectively the discharges are frequent. The working of the gun is simple. One man places one end of a feed-case full of cartridges into a hopper at the top of the gun, while another man turns a crank by which the gun is revolved. As soon as the supply of cartridges in one feed-case is exhausted, another case may be substituted without interrupting the revolution or the succession of the discharges. The average number of barrels composing the gun is ten. The bore of every barrel extends through from end to end, and the breech is chambered to receive the flanged center-fire metallic-case cartridge. The breech ends of all the barrels are firmly screwed into a disk or rear barrel-plate, which is fastened to the shaft, and the muzzles pass through another similar disk, called front barrel plate, on the same shaft. The shaft is considerably longer than the barrels, and projects beyond the muzzles, and also extends backward for some distance behind the breeches of the barrels. Directly behind the open barrels a cylinder of metal, called a carrier-block, is fastened to the shaft, and in the exterior surface of this carrier-block ten semi-cylindrical channels are cut, which form trough-like extensions of the cartridge-chambers of the barrels to the rear, and are



The Improved Gatling Gun and Feed-magazine.

designed to receive and guide the cartridges while they are thrust into the barrels, and to guide the empty cases while they are withdrawn. Behind the carrier-block the shaft carries another cylinder, called the lock-cylinder, in which ten guide-grooves are formed, which are parallel to the barrels, and in which slide ten long breech-plugs or locks, by which the cartridges are thrust into the barrels, and which close the barrels and resist the reaction of the charges when they are fired. Each plug or lock contains a spiral main-spring acting on a firing-pin, by which the charge is fired, so that the plug performs all the functions of a gun-lock, as well as of a breech-plug. The shaft, to which the group of barrels and both the carrier-block and the lock-cylinder are rigidly attached, is free to turn on its axis, the front end being journaled in the front part of the frame, and the rear end in a diaphragm in the breech-casing. The breech-casing extends to the rear far enough to contain not only the diaphragm through which the main shaft is journaled, but also to form in the rear of the diaphragm a cover for the gearing by which the shaft is revolved. This mechanism or gearing consists simply of a toothed wheel fastened to the shaft and worked by an endless screw on a small axle which passes transversely through the case at right angles to the shaft, and is furnished outside the case with a hand-crank. A cascabel-plate closes the end of the case. Each lock carries a hooked extractor, which snaps over and engages the cartridge-flange when the lock is pushed forward, and which, when the lock retreats, withdraws and ejects the empty case. The cartridge carrier-block is covered above the frame by a semi-cylindrical shell, which is provided at the top with an opening of suitable size and shape to permit a single cartridge to fall through it into one of the channels of the carrier-block, which it overlies. There is a trough extending upward from this opening and forming a hopper, in which a straight feed-case can be placed in a vertical position, containing a number of cartridges lying lengthwise across the case, one above another. Beneath the carrier-block everything is open so as to allow the cartridges or shells which are withdrawn by the extractors from the barrels to fall to the ground. Within the cylindrical breech-case attached to the frame a heavy ring not quite the length of the lock-cylinder is fastened to the case and diaphragm, which nearly fills the space between the inside of the case and the cylinder. Portions from the inside of this ring are so cut away as to leave a truncated, wedge-shaped, annular or spiral cam projecting from the inner surface of the ring, having two helicoidal edges inclined to each other and united by a short, flat plane. Against these edges the rear ends of the locks or breech-plugs continually bear, there being room enough for the locks to lie loosely within the parts of the ring which are cut away. The apex of the wedge-shaped cam points to the barrels. Each lock is held back against the cam by a lug or horn, projecting laterally from the end of the lock, and entering a groove made at the base of the cam, in the thin part of the ring.



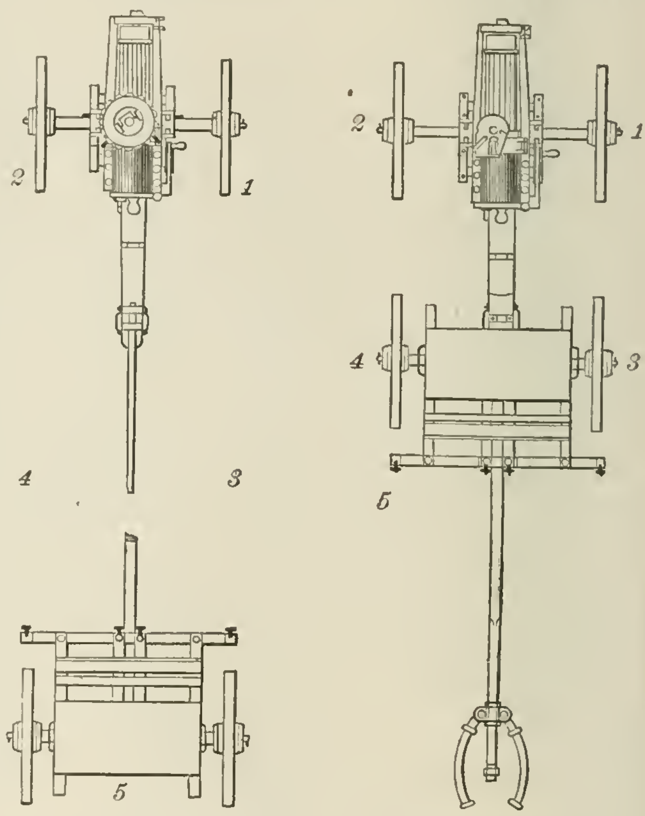
Barrels, Shaft and Casing.

The distance of the apex of the cam from the ends of the barrels is such that the breech-plugs or locks exactly fill the space, so that each plug there forms an abutment, which closes the breech of its barrel and abuts against the apex of the cam, which serves to resist the recoil of the plug when the charge is fired. It will be remembered that the locks are guided in grooves formed in the lock-cylinder, and therefore cannot deviate from their alignment with the barrels. From what has before been explained it will be understood that the ten barrels, the cartridge carrier-block, and the lock-cylinder carrying its ten locks, will, by turning a crank, revolve together about the axis of the central shaft, the lock-cylinder revolving within the stationary case and cam-ring, and the cartridge carrier-block revolving beneath the half-cylindrical shell which carries the hopper. The cartridges will, as the carrier-block channels come successively under the hopper, drop into the channels in front of the locks, and be kept in place by the hopper-shell. The revolution of the lock-cylinder carries the locks around with it, and causes them to receive a longitudinal reciprocal motion, by their ends sliding along the inclined surfaces of the stationary cam. Each lock, then, one after the other, is pushed forward toward its barrel. As the revolution of the parts keeps the locks in contact with the advancing side of the cam, each lock in succession closes its barrel, and its longitudinal motion ceases, while it passes the flat surface to the cam, and then each slides backward from its barrel when constrained to move along the retreating side of the cam by the corresponding cam-groove, and so on, each lock repeating these movements at each successive revolution of the shaft.

The position of the cam relatively to the cartridge-hopper is such that each lock is drawn backward to its full extent when it passes the hopper, so that the cartridges may fall into the carrier in front of the locks. The explosion of each cartridge takes place as its particular lock passes over the flat apex of the cam which resists the recoil.

The hammer is cocked by the knob or head at its rear end coming into contact with a flat *rib* located inside of the cam. This rib restrains the hammer from moving forward, while the forward movement of the body of the lock continues; the spiral mainspring is compressed until the revolution carries the hammer-knob beyond the end of the cocking-rib, when the hammer will spring forward, and strike with its point the center of the cartridge-head, and explode the charge. The point in the revolution at which the barrels are discharged is below and at one side of the axis. Thus it will be seen that, in the ten-barrel gun, one revolution of the barrels corresponds to one revolution of the locks, and delivers ten shots; a process which is repeated continuously, so long as the crank is turned and the cartridges are supplied. The gun can be unloaded of any cartridges not fired by removing the feed-case, opening the hopper, and reversing the motion of the crank. The locks are made interchangeable, and are strong and durable, but should they get out of order the gun is so constructed that any one or all of them can be in a few moments taken out and others inserted in their places, and so the gun can be kept in perfect working order at all times on the field of battle. In the new model the mechanism of the locks has been greatly strengthened as well as otherwise improved, and there are means at hand for their insertion and removal without taking off the cascabel-plate. These means consist of the perforation of the covering and back diaphragm in the outer casing, and by the closure of the apertures through both these plates by a single removable plug.

This is a very valuable improvement, inasmuch as the repairing or inspection of the locks is thereby greatly facilitated. The absence of one or more locks does not affect the working of the gun, except to diminish the intensity of fire in proportion to the number of locks removed. For each lock removed, however, one unexploded cartridge falls to the ground at each revolution of the gun. The gun is encased in a frame which has trunnions, and is mounted in the ordinary way, like a field-piece. The screw for elevating and depressing the breech works in a nut attached to the rail of the carriage in the usual way. An automatic traversing apparatus is applied by which a limited angular movement in a horizontal plane may be given to the gun, as follows: A cylinder having a cam-groove in its periphery is applied to the crank-axle, and the end of a cylindrical pin enters this groove. The cylindrical pin is attached to an arm which is connected to the elevating-screw; when the crank is turned the cam-groove travels back and forth on the cylindrical pin, swinging the gun from side to side through a sector of three degrees. The pin may be thrown out of gear with the cylinder and the gun be fired without swinging. The sector, covered automatically by the traverser, may be changed about five degrees on each side without moving the trail or suspending the firing. The cases which contain the cartridges, and which are applied to the hopper when it is desired to feed the gun, are long narrow boxes of sheet-tin reinforced by gun-metal, open only at the lower ends. The cross-section of the case is trapezoidal, the edge next to which the heads lie being wider than the cartridge-heads, while that which receives the points of the balls is of the width of the ball. This form enables all the cartridges in the case to assume a horizontal position, because the heads of the contiguous cartridges have room to roll over slightly, so as to lie partly alongside of each other, while the ball-ends are kept vertically over each other. Above the cartridges in the case is a weight which can be moved up and down by a thumb-piece. By the action of the hand pressing on the thumb-piece any desired pressure, regulating the rapidity of feed, can be given to the cartridges. Each straight feed-case holds just forty cartridges. The supply of cartridges to the gun may also be made by what is called the feed-drum (used only with the smaller calibers). This contains sixteen radial sections grouped vertically about the axis of the drum. Each section holds twenty cartridges, or each drum holds three hundred and twenty cartridges. The number of sections in the drum and the number of cartridges in each section may be varied. The drum rests vertically over the hopper, and feeds the cartridges automatically from the several sections in succession. Five men, including the gunner, are necessary for the service of the piece. With a greater number of cannoneers an exceptionally rapid and continuous fire can be sustained by assigning more men to the duties of exchanging empty for full feed-cases, and bringing up ammunition; but it is advisable not to expose too many men around the gun to the enemy's fire. The detachment may be maneuvered by the usual commands and means.

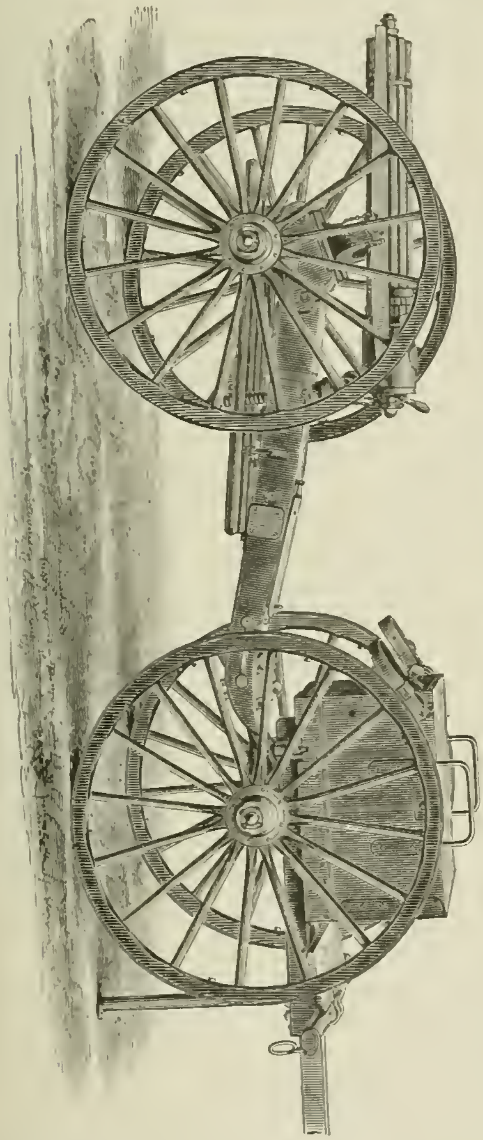


Posts of Cannoneers.

The cannoneers are numbered from *one* to *five*, and their posts at the piece unlimbered will be as follows: Nos. 1 and 3, on the right flank of the piece—No. 1 opposite the cascabel, and No. 3 opposite the rear end of the handspike; Nos. 2 and 4, on the left flank of the piece—No. 2 opposite the cascabel, and No. 4 opposite the rear end of the handspike; No. 5, is in rear of the limber-chest,—all facing to the front. Nos. 2, 4, and 5 wear haversacks slung from the left shoulder.

As soon as the piece is unlimbered, No. 1 ungears the crank and sees that it works easily. No. 2 sees that the hopper is clear for the insertion of a feed-case. No. 3 places the handspike, gets the traversing apparatus in action, and points the piece in the general direction required. Nos. 2, 4, and 5 go to the limber and place five filled feed-cases in their haversacks. After these duties are performed, all resume their positions.

At the command LOAD, No. 1 steps in to the crank, takes hold of the handle with his right hand, and is ready to turn the crank. No. 2 steps in and places a feed-case in the hopper, grasping it with his left hand



Gatling Gun. Carriage and Limber.

on the top, taking hold of the weight-stud with his right hand, so that he can gently press on the cartridges as they move, keeping the case perpendicular to the line of the bore. No. 3 seats himself on the trail-seat and sees that the gun is properly pointed. Nos. 4 and 5 stand fast. At the command FIRE, No. 1 turns the crank regularly without jerks. No. 2 attends the feed-case on the gun, seeing that it feeds regularly, withdrawing the empty case, and replacing it with a filled one, until he has inserted his last filled case in the hopper. He then calls out "case," when No. 4 steps forward and replaces the empty feed-cases with filled ones, and removes the empty ones. He then takes the empty cases to the limber, exchanges them for filled cases, or refills them as may be necessary, and places five filled cases in his haversack, and stands fast, when No. 4 steps forward to No. 2. No. 5 steps forward to the position just left by No. 4, and when No. 2 again calls "case," he performs the same duties that have just been designated for No. 4, and Nos. 4 and 5 perform these duties in succession during the continuance of the firing. No. 2 may drop the empty feed-cases on the ground, or place them in his haversack, taking care to have an uninterrupted flow of cartridges into the hopper kept up. At the command CEASE FIRING, No. 2 withdraws the feed-case from the hopper, places it in his haversack, and resumes the position which he had before the command LOAD was given. No. 1 turns the crank until the cartridges in the hopper have been fired, and then resumes his original position. No. 3 takes his original position, after No. 1 has stopped turning the crank. Nos. 4 and 5 stand fast, unless they are moving at the time the command is given, in which case they take care that No. 2 has five filled feed-cases in his haversack, and then resume their original positions. Should feed-drums be used instead of feed-cases, No. 2 should place the drum on the pintle as soon as the piece is unlimbered. Haversacks will not be worn by Nos. 2, 4, and 5, and when No. 2 gets to feeding from the last compartment of the feed-drum, he will call out "drum," when No. 4 or No. 5, as the case may be, will replace the empty drum, which No. 2 will lift off, by a filled drum, and will at once take the empty drum to the limber to be refilled. At the command CEASE FIRING, when the drum is used, No. 2 will continue to feed until all of the cartridges in the compartment of the drum then in use are exhausted. The methods of limbering and unlimbering, mounting and dismounting of the cannoneers, the intervals between the pieces, service of the piece with reduced numbers, etc., are all dependent upon the Field-artillery Tactics of the Nation using the gun. When the piece is limbered, Nos. 1 and 2 are opposite and one yard outside the naves of the carriage-wheels, Nos. 3 and 4 opposite and one yard outside the naves of the limber-wheels, the gunner in front of the limber-wheel, on the same line with Nos. 2 and 4, who are on the right of the piece, the odd numbers being on the left. The cannoneers are mounted and dismounted as prescribed in Artillery Tactics, except that the gunner and Nos. 1 and 2 mount on the limber of the piece, No. 2 in the middle. In drilling at the school of the piece, in garrison or camp, it will be well to remove the locks to prevent the unnecessary snapping of the springs, and the cartridges can then be run through the hopper at will, familiarizing the men with the use of the gun without waste of ammunition or injury to the locks.

The style of carriage depends somewhat upon the service for which the gun is intended. In the United States an ordinary field-carriage with limber has been used. The drawing shows the musket-caliber, ten-barrel Gatling gun, on carriage with limber complete. Recently a two-wheeled cart, with shafts for a horse, has been proposed by the Ordnance Department, intended to carry the gun and two ammunition-boxes, containing together 40 feed-cases, each holding 40 cartridges, so that the carriage takes with it 1600 cartridges in feed-cases. A space is also reserved in front of the axle for two boxes of cartridges containing 1000 each. The weight of the carriage without cartridges is about 500 lbs. This carriage is intended specially for service with cavalry.

The cartridge for the Gatling gun is made of No. 18 sheet-copper. The *canister* consists of a case terminated at one extremity by a hemispheroid of lead called the head; it contains for the 1-inch gun 15 bullets, .48-inch in diameter. The charge for this gun is ¾ ounce of mortar-powder and 6 grains of fulminate; that for the .50-inch gun is 70 grains of musket-powder and ½ grain of fulminate. The fulminate used is composed of fulminate of mercury, 3 parts;

pulverized niter, 2 parts; glass dust, ½ part; chlorate of potassa, 2 parts. This is well moistened with gum-arabic water.

The *solid shot* consists of a case containing the above composition and charge of powder, with an elongated bullet weighing 8 ounces for the 1 inch, and 450 grains for the .50-inch and .45-inch guns. Canister is only used with the 1-inch gun. The cartridges are put up and issued from the arsenals in pasteboard packages, and when required for service enough are opened to fill the tin feed-cases carried in the limbers of the pieces. The ammunition-chests of the caissons are filled with unbroken packages. For the .45-inch gun the ammunition is interchangeable with that for the regulation infantry rifle.

The character of the rifling of Gatling guns is uniform groove, making one turn in 72 inches for the 1-inch gun, one turn in 42 inches for the .50-inch, and one in 22 inches for the .45-inch gun. The effective range is contemplated at from 200 to 1200 yards, or the zone of infantry fire.

The Gatling gun has recently undergone a great improvement, both in the matter of its details and in its feed. The drawing at the head of this article represents one of the improved guns, having six, eight, and ten barrels, each barrel having its corresponding lock. The barrels and locks revolve together, inside the outer stationary case. But in addition to this action, the locks have a forward and backward motion of their own. The forward motion places the cartridges in the chambers of the barrels and closes the breech at each discharge; while the backward motion extracts the empty cartridge-case after firing. The cartridges are supplied to the gun by magazines consisting of a circular drum of a width slightly greater than the length of the cartridge. On the two circular plates which form the ends of the drum are spiral grooves running from the center to the outer edge, in which the ends of the cartridges are supported and guided in and out of the magazine. In the center of the magazine, between the two aforesaid grooved plates, are two other circular plates which revolve round the central shaft, having a number of slots radiating from the center, and joined near the outer edge by pins. These two plates when revolved force the cartridges along the aforesaid grooves in the end plates out of the magazine into the receiver of the gun, and in front of the locks. The center plates of the magazine are revolved by projections on the receiver which engage with pins that join the center plates in the form of gear. The magazine is held in its place over the receiver by flanges on each side of the hopper with two under-cut slots in which two projections on the magazine fit so as to lock it in its place. The slots are of unequal size, so that the magazine cannot be wrongly inserted. On the left-hand side of the hopper are two wedge-shaped points that are let down into the receiver, which eject the empty shell from the receiver when extracted from the chambers by backward motion of the lock. The extractor is so formed that its hook remains always in front of the cartridge-head, and it is rendered stronger by making it double its former width circumferentially. It has no spring and does not lift the lock by springing over the cartridge-head. The cartridge is therefore always struck centrally instead of at the side. The extractor is so arranged that after each discharge it holds back the firing-pin so that its point does not project in front of the lock-face until released by the cocking-ring, making it impossible for a premature explosion of the cartridge to take place by the forward motion of the lock coming in contact with the cartridge-heads. In firing at high elevations, the cartridges are prevented from sliding back into the mechanism through the orifice in the front lock-flange, either when the locks are in or out of the gun, by flanging the openings and making the lock to correspond. The gun has been fired in a vertical position with as much ease and perfection as when horizontal. The rear portion of the lock is supported by a T-way at the center instead of at the bottom, in order to prevent all possibility of jamming by dust or sand. The gun is mounted on trunnions two inches below the center, and is elevated and depressed by means of a circular elevating arc connected at both extremities with the gun, and actuated by gearing so arranged that elevation and depression are indicated in degrees and minutes. A horizontal limb for direction is graduated in the same way. Both kinds of gear are so arranged that they can be instantly thrown out, allowing the gun to move rapidly in all directions by means of a long lever. The automatic oscillator is dispensed with, the effect being produced by hand movement of the rear lever. An adjustment of the lateral training is obtained by means of stops on the turn-table of the carriage, which can be set to any required number of degrees. The gun can be elevated to 74 degrees and depressed to 78 degrees. It is provided with two sights, viz., one on each side. A device is added to serve the purpose of throwing the cocking-ring out of use at will, and prevents the cocking of the firing-pins. This is of advantage during drill, and allows firing motion to take place without snapping and thereby injuring the firing-pins. The barrels are locked into the rear flange-plate instead of being screwed as heretofore. In case of accident to lock or barrel the lock can be instantly removed, and the firing continued with the remaining locks.

The gun can be fired with the crank either at the rear or side. When at the side, the gun fires at each turn of the crank about one half the number of shots to the number of barrels in the gun; when at the rear, it fires at each turn of the crank as many shots as there are barrels in the gun. The feed-magazines hold from 65 to 104 cartridges each, and weigh from 10 to 24½ lbs. when full of cartridges. The musket-caliber guns weigh from 100 to 237 lbs. each, according to the number and length of the barrels.

It is believed that the best organization for Gatling guns is that of the battery in field-artillery, and that the batteries should belong to the division rather than to a smaller organization. Circumstances may arise that will make the use of the guns in batteries of six or eight pieces enormously valuable; but in any event, better care can be taken of the guns, better instruction given to the men, and a better discipline and *esprit de corps* kept up by a battery organization than by distributing them singly or in sections to serve with infantry regiments. Before any action, the batteries could, if necessary, be assigned to brigades, and the pieces could be used at the discretion of the Commanding General in field-works, trenches, to guard, or drive the enemy from hollow roads, fords, bridges, and ravines, or to assist infantry in holding exposed positions. For detailed description of parts, see the appropriate headings. See *Camel-gun* and *Machine-gun*.

GAUGE.—An apparatus for measuring any special force or dimension; thus we have *pressure-gauge, wind-gauge, rain-gauge, wire-gauge*, etc. The simplest form of gauge of dimension is the common *wire-gauge*, by which the diameter of wire is measured. It is simply an oblong plate of steel, with notches of different widths cut upon the edge; these are numbered, and the size of the wire is determined by trying it in the different notches until the one is found which it exactly fits. The thickness of sheet-metal is tried by the same gauge. There is a great want of uniformity in all these gauges—the Birmingham gauge for iron wire, sheet-iron, and steel differing from that used for brass, silver, gold, etc., and these, again, from the Lancashire gauges. It has been proposed, in order to obtain uniformity, and to enable definite descriptions and orders to be given with accuracy and certainty, that instead of the arbitrary numbers of varying signification now in use, decimal parts of an inch, tenths, hundredths, thousandths, or still smaller fractions, if necessary, be used, and that these be used for all diameters and thicknesses, such as wires, sheet-metals, buttons, watch-glasses, etc.; but such a scale has not yet come into general use. The gauge commonly used for large diameters is a rule with a groove cut lengthwise down the middle. Another metal rule, with a brass head, slides in this, and by means of a thumb-pin may be pushed out at pleasure. The object to be measured is placed between the inside of the slide and the end of the rule, and the width of this space is measured by graduations on the middle metal slide. The engraving shows a combination of sizes known as step-gauges. This device is very valuable for general use in the arsenal and armory, for testing holes, adjusting calipers, etc. They are made in sets of any number of gauges, as may be desired for the particular kind of work. The width of the disks increases with their diameter. A very elegant and delicate gauge has recently come into use for measuring watch-glasses, and is applicable to many other purposes. On an oblong piece of sheet-metal two straight metal ridges are fixed in such a manner that they shall be inclined at a given angle to each other. Now, let us suppose the angle to be such that the distance between the upper extremities is 2 inches and that between the lower ends is 1 inch, while the lengths of the metal ridges are 10 inches. It is evident that for every inch of descent from the upper to toward the lower ends there will be a narrowing equal to $\frac{1}{10}$ of an inch; and for every tenth of an inch of such descent there will be a narrowing of $\frac{1}{100}$ of an inch, and so on: thus we may, by graduating downwards from the top, measure tenths by units, hundredths by tenths, and so on to still finer quantities if required. This is applicable to lengths as well as diameters. By means of fine screws with large graduated heads Messrs. Whitworth have measured small pieces of steel to the one-millionth of an inch. See *Anemometer*, *Calipers*, *Corrective Gauges*, *Micrometer*, *Pressure-gauge*, *Star-gauge*, and *Wire-gauge*.

Step-gauges.

GAUNTLET.—Armor for the hand and arm, made either of scales or mail, and used in the Middle Ages. It formed part of the armor of knights and men-at-arms. See *Gantlet*.

GAUTIER TELEMETER.—This telemeter, invented by Captain Gautier, of the French army, is an instrument for measuring, with a great degree of approximation, any difference, not exceeding three degrees, which may be exhibited in the bearing of a distant object by viewing it from different points of a base-line transverse to its general direction from the observer. The instrument, in its simplicity, accuracy, and portability, recommends itself in all cases where a knowledge of distances is desired at any moment and with the least possible delay; such, for instance, as range-finding, river-crossing, reconnoitering, and the like. A slight acquaintance with its use on such occasions enables the observer to estimate, with more than ordinary promptitude and precision, the distance which it might be all-important to obtain. The instrument, shown in Fig. 1, resembles in

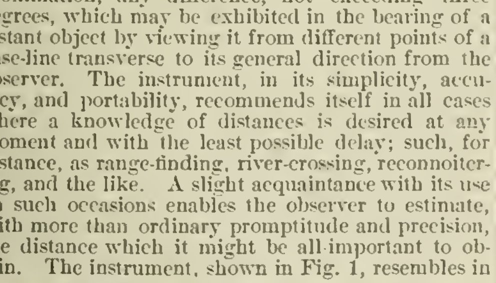


Fig. 1.

shape and size one barrel of an ordinary reconnoitering or field glass. The case in which it is carried is fashioned so as to answer as a handle for holding the instrument when making observations. Within the barrel of the instrument are placed two mirrors at an angle of about 45 degrees with each other; this angle can be varied within certain limits by means of a milled-headed screw acting on one of them. The mirrors are thus made to operate upon the principle of the sextant. A slot on one side of the barrel permits the rays of light from an object to fall upon one of the mirrors, from whence they are reflected upon the other mirror, and the image is seen through the eye-glass at the small end of the instrument. At the front or large end is fixed, in a ring surrounding the barrel, a prism, whose displacement modifies the direction of any object seen through it. At the rear of the instrument is a small eye-glass, by means of which the observer sees, *over* the mirrors and through the prism, the object which is before him, and by double reflection *in* the mirrors the object to the side of him. The semi-revolution of the movable ring containing the prism corresponds to a displacement of the object toward the left of about three degrees. The ring is provided with a graduated scale containing numbers, the use of which will be explained.

Suppose C, in Fig. 2, to be the object, and A the point from which the distance A C is to be determined. Select some distant object, as M, for the *signal*, the direction A M to it making with the line A C an angle a little greater than 90 degrees. From the point A measure the base, A B, in the prolongation of the line to the *signal*. After having adjusted the telemeter upon the case, which serves as a vertical handle, turn the ring until the word "infinity" is brought opposite the fixed index or arrow. This brings the prism to its *initial position*. A small opening in the under part of the instrument, exhibiting the mirror index, enables the observer to assure himself that the movable mirror is at its *mean position*, which is indicated by a fixed mark. The telemeter is then ready for operation, and the observer places himself at A, so that the object C will be on his right. (The right is here chosen merely for purpose of illustration. The observation can be as easily made with the object on the left.) The instrument is held in the left hand, the fingers of which clasp the barrel firmly to the handle (the case). The observer, facing the signal M and sighting through the eye-glass upon the signal, turns, with the right hand, the milled screw until the image of the object C coincides with the signal M. Leaving the screw in this position, he retires to the other end, B, of the base-line, where, holding the instrument as before, he sights upon the signal, and turning the graduated ring on the front end, makes the images again coincide. This done, there will be found on the ring opposite the fixed index a number which, being multiplied by the number of units in the base-line, will give the required distance A C in terms of the unit used in measuring the base. This is the method of a *fixed base*. Another method is by means of a *proportional base*, which is, instead of measuring a base as just described, a certain factor is selected on the ring and the instrument set to it; then by moving back in the direction A B until the images coincide, the distance thus moved over will be the base, which is then measured and multiplied by the selected factor. This method has the advantage of eliminating the errors of reading the movable ring.

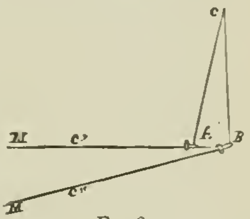

Fig. 2.

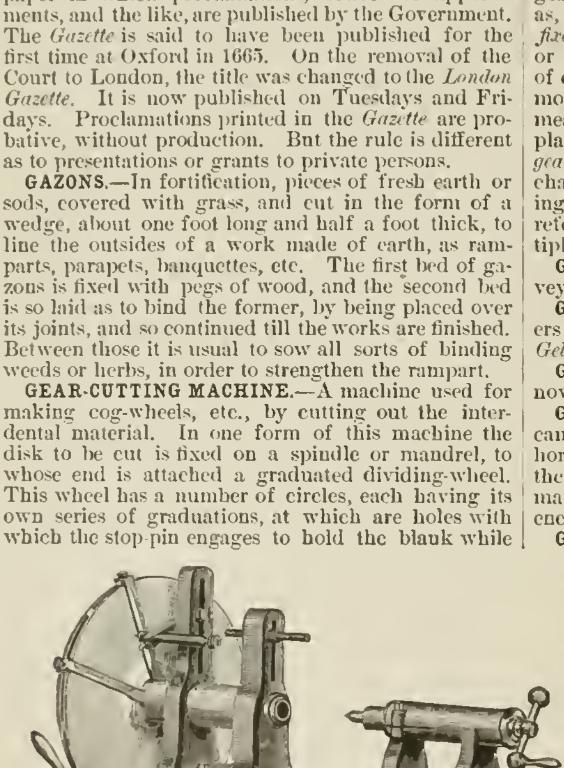
A base of $\frac{1}{100}$ of the distance suffices in general for obtaining the exactness of measurement required in military operations. It is necessary always that the object and the signal be well defined and of a convenient form and size, and that the observer be sufficiently skilled with the instrument to make with precision the necessary sightings, and to make the proper alignment of the two stations upon the signal. In a case where a good natural signal is found, distances up to 2000 meters can be readily measured in less than two minutes. If the conditions are less favorable, the measurements may be effected by employing bases of $\frac{1}{50}$ or of $\frac{1}{30}$. Whatever be the method employed, the immediate result of the operation is the knowledge of the relation between the distance sought and the base. The base may be expressed according to any unit of measurement, and the distance will be correspondingly expressed. If the base is measured in yards, the distance will be yards, etc. See *Telemeter.*

GAZE.—A term in Heraldry. When a beast of the chase, as a hart or stag, is represented as *affrontée*, or full-faced, it is said to be at gaze.

GAZETTE.—A gazette was a Venetian coin worth somewhat less than a farthing; and the name was hence applied to a sort of gossiping sheet, or primitive newspaper, that was sold for that sum at Venice. In its English acceptation it means the official newspaper in which proclamations, notices of appointments, and the like, are published by the Government. The *Gazette* is said to have been published for the first time at Oxford in 1665. On the removal of the Court to London, the title was changed to the *London Gazette.* It is now published on Tuesdays and Fridays. Proclamations printed in the *Gazette* are probative, without production. But the rule is different as to presentations or grants to private persons.

GAZONS.—In fortification, pieces of fresh earth or sods, covered with grass, and cut in the form of a wedge, about one foot long and half a foot thick, to line the outsides of a work made of earth, as ramparts, parapets, banquettes, etc. The first bed of gazons is fixed with pegs of wood, and the second bed is so laid as to bind the former, by being placed over its joints, and so continued till the works are finished. Between those it is usual to sow all sorts of binding weeds or herbs, in order to strengthen the rampart.

GEAR-CUTTING MACHINE.—A machine used for making cog-wheels, etc., by cutting out the interdental material. In one form of this machine the disk to be cut is fixed on a spindle or mandrel, to whose end is attached a graduated dividing-wheel. This wheel has a number of circles, each having its own series of graduations, at which are holes with which the stop-pin engages to hold the blank while



Gear-cutting Attachment.

the circular cutter on the slide-rest does its work. This cutter has a shape coinciding with that of the interdental space of the wheel required. The mandrel of the cutter-wheel is rotated by a band, and the cutter is fed by a hand-crank and feed-screw, so as to traverse past the face of the wheel under treatment. The drawing shows the gear-cutting attachment to the milling-machine, used in armories for cutting larger and heavier wheels than can be cut with the ordinary apparatus. It swings 13 inches, and is supplied with a 20-inch index which contains 4294 holes. It will divide all numbers to 75, and all even numbers to 150.

GEARING.—1. Warlike accouterments; military harness and apparatus for lifting and training heavy ordnance; equipage. 2. A term applied to the parts of machinery by which motion in one part of a machine is communicated to another; gearing consists in general of toothed-wheels, friction-wheels, endless bands, screws, etc., or of a combination of these. When the communication between the two parts of the machine is interrupted, the machine is said to be *out of gear;* and when the communication is restored, it is said to be *in gear.* In the case of the grinding-mill, e.g., driven by a steam engine, the gearing usually consists of an endless band which communicates motion from the axle of the fly-wheel to that of the drum. If the band were slipped off from one wheel, or slackened so that motion could not be communicated by means of it, then the machine would be *out of gear.* Gearing which can be placed in and out of gear is called *movable gearing;* that which cannot, as, for instance, the wheel-work of a watch, is called *fixed gearing.* Gearing which consists of wheel-work or endless screws is put out of gear either by means of one of the wheels sliding along its axis, or being moved out of its place horizontally or vertically by means of a lever. *Straight gearing* is used when the planes of motion are parallel to each other; *beveled gearing,* when the direction of the plane of motion is changed. Gearing has also for its object the increasing or diminishing of the original velocity, and in reference to this is distinguished by the term "multiplying" or "retarding."

GEAT.—The hole through which the metal is conveyed to the mold in casting ordnance. See *Casting.*

GEBEGIS.—A term formerly applied to the armorers among the Turks. It is now nearly obsolete. See *Gelibach.*

GEBELIS.—A Turkish corps of picked men, renowned for their perseverance and fighting qualities.

GEBELUS.—Every Timariot in Turkey, during a campaign, is obliged to receive a certain number of horsemen, who are called *Gebelus,* and to support them at his own expense. He is directed to take as many as would annually cost 3000 *aspres* for subsistence.

GELIBACH.—A sort of Superintendent or Chief of the *Gebegis* among the Turks. He is only subordinate to the Toppibachi, or the Grand Master of the Turkish artillery.

GEMOTE.—Besides the great Council of the Nation—the *Witena-gemot,* or, as we more usually spell it, the Witenagemót—which corresponded to the Reichstage of the Franks, and which, though it took the place of the still more ancient meetings of the whole Nation, to which Tacitus refers as characteristic institutions of the Teutonic tribes in his day, was a representative, though not perhaps an elective body, there were amongst the Anglo-Saxons numerous minor motes or moots, which did not take part of the representative character. The existence of these is an instance of the manner in which the spirit of localization has always maintained its ground, and balanced that of centralization amongst the Germanic Nations, and more particularly in England. There was the *Shiregemot,* or County Court, which met twice in a year; and the *Burg-gemot,* which met thrice; also the *Hundred-gemot,* which met every month, and an extraordinary meeting of which was held twice a year; the Hallegemote, or *Court-baron.* These institutions excluded not only central despotism, but local tyranny in the shape of individual caprice. The Ealdorman decided only with the assent of the Shire-gemote, just as the King was dependent upon that of the Witan. (Lappenberg by Thorpe, ii. p. 322.)

GENDARMES—GENS D'ARMES.—Originally, and up to the time of the first French Revolution, the most distinguished cavalry corps in the service of the Bourbon Kings, to whom they formed a sort of body-guard. Under existing arrangements, the Gendarmes constitute a military police, and comprise both cavalry and infantry. The force consists principally of soldiers taken from the army, generally on account of intelligence and good conduct. The men receive much higher pay than the rest of the army, of which, however, the corps is a part, and they are liable in cases of emergency to be sent on active service. The Gendarmes amount to about 27,000 men, and are intrusted with the execution of many of the most delicate details of government.

GENERAL.—1. A term for the roll of the drum which calls the troops together. To "beat the general" is a phrase drawn from the French drum-instructors, *Battre la générale*.—2. The highest military title in the United States army until very recently, and the highest military title below that of Field Marshal in European armies. A General ordinarily commands no body of men less than an army. See *General Officer*.

GENERAL COURT-MARTIAL.—In the army, a tribunal for the general examination and punishment of offenders against martial law, or against good order and discipline.

The following is a form of record for a General Court-Martial:

Page 1. CASE 1.

PROCEEDINGS OF A GENERAL COURT-MARTIAL WHICH CONVENED AT ——, ——, PURSUANT TO THE FOLLOWING ORDER:

HEADQUARTERS DEPARTMENT OF —— ——,
——, ——, 187 .

Special Orders }
No. —. }

[EXTRACT.]

A General Court-Martial is hereby appointed to convene at ——, on —— the —— of —— at 10 o'clock A.M., or as soon thereafter as practicable, for the trial of such persons as may be brought before it by authority from these Headquarters.

Detail for the Court.

1. Colonel —— ——, —— Artillery.
2. Major —— ——, —— Cavalry.
3. Surgeon —— ——, U. S. Army.
4. Captain —— ——, —— Infantry.
5. Captain —— ——, —— Artillery.
6. Captain —— ——, —— Infantry.
7. Assistant Surgeon —— ——, U. S. Army.
8. First Lieutenant —— ——, —— Infantry.
9. First Lieutenant —— ——, Ordnance Dep't.

First Lieutenant —— ——, —— U. S. Artillery, is appointed Judge Advocate of the Court.

No other officers than those named can be assembled without manifest injury to the service.

By command of Major General ——:

—— ——,
Assistant Adjutant General.

Page 2. CASE 1.

—— BARRACKS,
——, ——,
——, 187 .

The Court convened, pursuant to the foregoing order, at 10 o'clock A.M.

Present:

1. Colonel —— ——, —— U. S. Artillery.
2. Major —— ——, —— U. S. Cavalry.
3. Surgeon —— ——, U. S. Army.
4. Captain —— ——, —— U. S. Infantry.
5. Captain —— ——, —— U. S. Artillery.
6. Captain —— ——, —— U. S. Infantry.
7. Assistant Surgeon —— ——, U. S. Army.

First Lieutenant —— ——, —— U. S. Artillery, Judge Advocate.

Absent:

1. First Lieutenant —— ——, —— U. S. Infantry.
2. First Lieutenant —— ——, Ordnance Dep't.

(Here set forth the cause of absence of any absent member, if the same is known. It is the duty of the Judge Advocate to ascertain, if possible, the cause of absence and record it, and in cases of sickness medical certificates should generally, when practicable, be furnished by the absent members, and appended to the record.)

The Court then proceeded to the trial of —— ——, —— Regiment U. S. Infantry, who thereupon came before the Court, and having heard the order convening it read, was asked if he had any objection to any member present, named in the order: to which he replied in the negative, [or, the Accused (*or* Prisoner, *as the case may be*) submitted the following objection to —— ——].

(Here insert the objection.)

The challenged member stated that:

(Here insert the statement of challenged member.)

The Court was thereupon closed, the challenged member and the Prisoner retiring, and, after due deliberation, the Court having reopened, the challenged member and the Prisoner resumed their seats, and the decision of the Court was announced by the Judge Advocate that the objection of the Prisoner is sustained, and [Here insert challenged member's name and rank] is therefore excused from serving as a member of the Court in this case; [or, that the objection of the Prisoner is overruled].

(Objection can only be urged to one member at a time, for cause stated to the Court, and a record as above must be made in each instance. If the person on trial has no objection to offer, the record will continue as follows:)

The members of the Court were then severally duly sworn by the Judge Advocate, and the Judge Advocate was then duly sworn by the President of the Court: all of which oaths were administered in the presence of the Prisoner, or Accused.

(The oaths are given in the 84th and 85th Articles of War. Should the person on trial desire to introduce counsel, he should now make application, and the record will continue as follows:)

The Prisoner now requested permission of the Court to introduce —— —— as his Counsel, which request was granted.

(The Counsel for Prisoner, when needed by him to assist in an objection to a member or examination on the *voire dire*, may be introduced to the Court immediately after reading the order appointing it. The practice of all Courts-Martial is to receive as Counsel any officer of the army or any lawyer in good standing, or other competent person, but Courts-Martial may, like the Civil Courts of the United States of criminal jurisdiction, decline to receive any individual as Counsel who, by reason of character or ignorance, would, in the Court's judgment, be an improper person to appear before it. In such case the record should state the reasons. If any delay in the trial is desired, application should now be made, and in passing upon the request the Court should be governed by the 93d Article of War.)

The Prisoner was then duly arraigned upon the following charge and specification:

Charge: —— —— —— —— ——

Specification: —— —— —— —— ——.

To which the Prisoner pleaded as follows:
To the specification: "Guilty" [*or*, "Not Guilty"].
To the charge: "Guilty" [*or*, "Not Guilty"].

(Or the Prisoner may, in lieu of pleading to the merits, put in a plea in bar of trial—to the jurisdiction, or special plea, such as autrefois acquit or convict, pardon, on which the Court will have to pass.)

Captain —— ——, of the —— U. S. Infantry, a witness for the prosecution, then came before the Court and was duly sworn by the Judge Advocate, and testified as follows:

(The oath is given in the 92d Article of War.)

Question, by the Judge Advocate: * * * *
Answer: * * * * * *

CROSS-EXAMINATION.

Question, by the Prisoner: * * * * *
Answer: * * * * * * *
* * * * * * * *

(If the person on trial declines to cross-examine the witness, it should so appear on the record. If new matter has been elicited in the cross-examination, bearing upon the issue of the trial, the Judge Advocate may re-examine the witness, should the facts require it. After the examination-in-chief, the cross-examination and re-examination, the Court can ask such questions as it may deem necessary. A question by a member of the Court, if objected to and rejected, must be recorded as "by a member." If not objected to, the record will continue as follows:)

Question, by the Court: * * * * *
Answer: * * * * * *
* * * * * * * *

(After all the testimony for the prosecution has been adduced, the record will continue as follows:)

The Judge Advocate then announced that the prosecution rested.

The Court then, at — o'clock P.M., adjourned to meet to-morrow at 10 o'clock A.M.

——— ———.
1st Lieutenant —— *U. S. Artillery*,
Judge Advocate.

SECOND DAY.
—— BARRACKS,
——, ——,
——, 187

The Court met, pursuant to the foregoing order and adjournment, at 10 o'clock A.M.

Present:

(Here give names, rank, etc., of members present and of Judge Advocate in manner stated.)

Absent:

(Names, rank, and cause of absence.)

The Prisoner (and ——— ———, his Counsel) also present.

The proceedings of the —— instant were then read and approved.

Sergeant ——— ———, of the —— U. S. Infantry, a witness for the defense, then came before the Court and was duly sworn, and testified as follows:

Question, by the Prisoner: * * *
Answer: * * * * *
* * * * * *

CROSS-EXAMINATION.

Question, by Judge Advocate: * * *
Answer: * * * * *
* * * * * *

Question, by the Court: * * * *
Answer: * * * * *
* * * * * *

The Prisoner having no further testimony to offer, made the following statement in his defense, [*or*, submitted a written statement in his defense,] which was read to the Court by the Prisoner, [or by his Counsel, or by the Judge Advocate,] and is hereto annexed, marked "A."

(The statement of the Accused, when in writing, or written argument in his defense, and all written pleas in bar of trial or abatement, should be signed by the Prisoner himself and appended to the record, and referred to in the proceedings as having been submitted by him, whether he is defended by Counsel or not.)

The Judge Advocate replied as follows:

(Here insert the remarks of the Judge Advocate, if verbal; if written, they should be read and annexed as in case of the defense; or,)

[The Judge Advocate submitted the case without remark.]

The Court was then cleared and closed for deliberation, and having maturely considered the evidence adduced, finds the Prisoner, ——— ———, —— U. S. Infantry:

Of the specification: "Guilty" [*or*, "Not Guilty"]
Of the charge: "Guilty" [*or*, "Not Guilty"]

And the Court does therefore sentence him, ——— ———, —— of —— Regiment U. S. Infantry, to ——— ———. [*or*, And the Court does therefore acquit him, ——— ———, —— of —— Regiment U. S. Infantry.]

——— ———,
Colonel —— *U. S. Artillery*,
President.

——— ———,
1st Lieut. —— *U. S. Artillery*,
Judge Advocate.

(The following will be added to the record of the last case brought before the Court:)

There being no further business before it, the Court then, at —— o'clock — M., adjourned *sine die*.

——— ———,
Colonel —— *U. S. Artillery*,
President.

——— ———,
1st Lieut. —— *U. S. Artillery*,
Judge Advocate.

(A space of one page should be left at the close of each record, for the decisions and orders of the Reviewing Authority. The proceedings should be recorded on legal-cap paper, each record folded in four folds, and indorsed on the first fold as follows:)

—— BARRACKS,
——, ——,
——, 187 .

Proceedings of a General Court-Martial, convened by Special Orders No. —, dated Headquarters Department of the ——, ——, 187 .

Colonel I —— *V* ——,
—— *Artillery*,
President.

1st Lieut. A —— *B* —— *G* ——,
—— *Artillery*,
Judge Advocate.

CASE TRIED.
Private E —— F ——,
—— Artillery.

See *Courts-Martial*.

GENERAL DES GALERES.—A Commander of the Galleys, an officer of high rank and extensive jurisdiction in France.

GENERAL DES VIVRES.—A sort of Chief Commissary or Superintendent General of Stores, whose functions were to provide ammunition, bread, and biscuit for the French army.

GENERAL GUIDES.—In each Infantry Battalion of the United States army there are two general guides selected by the Colonel from the Sergeants most distinguished for carriage under arms and accuracy in marching. The general guides are posted in the line of file-closers, opposite the right and left flanks of the battalion; the one on the right of the battalion is designated *right general guide;* the other, *left general guide*.

GENERAL HOSPITALS.—Hospitals specially formed, on the outbreak of a war, for the reception of the sick and wounded who can no longer be kept in the field-hospital. They are of such importance in a campaign that the best position should be chosen for them, both as regards safety and for sanitary reasons. General hospitals should be within easy distance of the army by rail or water. In selecting buildings for such purposes, ventilation and drainage are of primary importance. Huts and tents are frequently used as general hospitals, and are always preferable to private houses, as the latter are often too small for the purpose required of them, and do not always afford the regulation cubic space of air. The size of general hospitals should be limited to the reception of 500 or 600 men at a time; and when it can be managed, they should be cleared out as quickly as possible, and the invalids sent home to be distributed among the military hospitals. Considering the vastness of the armies of the present day, the subject of hospital accommodation is a difficult question; the care of the sick and wounded must therefore, to some extent, be left to the many kind and liberal people who follow armies with the view of attending on the sick, and of distributing the many comforts they take with them, such as clothing, medical and other stores, that have been collected and forwarded, not only from the country of the sick and wounded, but from foreign nations. Such, it is happy to think, is the sympathetic and loving feeling evinced nowadays by the good and benevolent when war breaks out.

GENERALISSIMO.—The Chief Officer in command of an army. This word is used in most foreign countries, and was first employed to designate the absolute authority of Cardinal Richelieu when he went to command the French army in Italy.

GENERAL MAJOR.—A particular rank or appointment, whose functions correspond with those of a Ci-devant Marshal of France. This situation is intrusted to a General Officer, and is only known among the armies of Russia and some other Northern Powers. He takes precedence in the same manner that our Major Generals do of all Brigadier Generals and Colonels, and is subordinate to Lieutenant Generals. Frequently called *Général de Bataille*.

GENERAL OFFICER.—An officer of the General Staff of an army to whom is intrusted the command of a body of men not less in strength than a brigade. In an army of very large proportions the normal sequence of command would be the following: the General Commanding-in-Chief, the Generalissimo, or Field Marshal, would command the whole force; the Generals would have the separate *Corps d'Armée;* the Lieutenant Generals, wings of those *Corps d'Armée;* the Major Generals, divisions in the wings; and Brigadier Generals, brigades in the divisions. In practice, however, an army is rarely large enough to allow of this exact scheme of a military hierarchy being strictly carried out.

In the British service Colonels become Major Generals (except in cases of selection for very distinguished service) in order of seniority, provided each has served on full pay for a certain number of years; promotion to be Lieutenant Generals and Generals follows in exact order of seniority. From the last, promotion to the exceptional rank of Field Marshal is conferred in rare instances by the special favor of the Sovereign, who represents in person the sole command and possesses the patronage of the whole land forces. In addition to the Colonels who become effective Generals, officers who have retired on half-pay at earlier periods of their careers rise by seniority to the rank of General Officers; but they continue, notwithstanding, to receive only the half-pay of the rank in which they retired. With regard to remuneration, General Officers hold 164 honorary Colonelcies of regiments, worth, with few exceptions, £1000 each per annum, and the remainder receive *unattached* pay of £600 a year, if they have been in the Guards; £1 6*s*.3*d*. a day, if in the Artillery or Engineers; and £1 5*s*. a day, if previously in the Line. This pay is received during non-activity, but when employed actively a General receives, in addition, £5 13*s*. 9*d*. a day; a Lieutenant General, £3 15*s*. 10*d*.; and a Major General, £1 17*s*. 11*d*., besides various allowances. The only Generals' commands in the British service are, during peace, the command-in-chief of the army generally and of the forces in India, and sometimes in Ireland. In the estimates for 1876–77 there are 7 Lieutenant Generals, 18 Major Generals, and 5 Brigadier Generals employed actively, exclusive of the numbers serving in India. The last-named rank is only a temporary one in the English service, and conferred very commonly on the senior regimental officer of the corps composing the brigade: during duty as Brigadier he receives £1 8*s*. 6*d*. a day in addition to regimental or other pay. *Captain General* is a rank very rarely conferred by the Sovereign, who holds it *ex officio.* There has been no Captain General other than the Sovereign during the present century.

In the United States the word *General* is used with much license, both in military and civil affairs. Besides Brigadier and Major General we have a Lieutenant General, Commissary General, Quartermaster General, etc. In the militia of the several States there are officers with similar designations and duties. In law we find the Attorney General of the United States, and similar officers in most of the States. The head of the powerful Society of the Order of Jesus is known as the General. The French army has Generals of Division and Lieutenant Generals.

GENERAL OF THE ARMY.—A title given to the General in the United States army. The Revised Statutes provide that when a vacancy occurs in the office of General or Lieutenant General such office shall cease, and all enactments creating or regulating such offices shall, respectively, be held to be repealed. While the office existed, the military establishment was under the orders of the General of the Army in all that pertained to its discipline and military control, and all orders and instructions relating to military operations, or affecting the military control and discipline of the army, issued by the President or the Secretary of War, were promulgated through the General of the Army. With the retirement of General William T. Sherman in 1884, the office of General of the Army ceased, and at present the rank of Lieutenant General is the highest in the United States army. The General of the Army, while in office, was permitted to have a number of Aids, not exceeding six, who held, while serving on his Staff, the rank of Colonel of cavalry. See *General Officer*.

GENERAL ORDERS.—Orders issued to announce the time and place of issues and payments; hours for roll-calls and duties; the number and kind of orderlies, and the time when they shall be relieved; police regulations, and the prohibitions required by circumstances and localities; returns to be made, and their forms; laws and regulations for the army; promotions and appointments; eulogies or censures to corps or individuals, and generally whatever it may be important to publish to the whole command. See *Orders* and *Special Orders*.

GENERAL SERVICE.—In the United States army, the whole number of the general-service men of all grades and designations allowed as clerks for Division, Department, and District Headquarters, and for Superintendents of the Recruiting Service, is as follows: 14 Sergeants, 28 Corporals, 109 Privates, and 9 Topographical Assistants. The rates of commutation of rations, fuel, and quarters of the general-service clerks are fixed by the Secretary of War. The General of the Army determines from time to time the distribution that shall be made of the clerks, according to the exigencies of the service, among the several commands, and the above number must include all those on duty in the Adjutant General's, Quartermaster's, Subsistence, Medical, and all other Staff departments. The men of the general-service detachment are not employed on any other than clerical duties. If Hospital Stewards are employed for clerical duty in the offices of the Medical Directors, they must also be included in the total number allowed, and rated, so far as commutation is concerned only, as privates. In addition to the above number for *clerks*, the Commanding Generals of Military Divisions and Departments, the Commanding Officer, District of New Mexico, and the Superintendents of the Recruiting Service, may, if it be necessary, detail enlisted men from troops under their command as *messengers*, not to exceed five for each Division Department, two for the District named, and one to each Superintendent. Enlisted men so detailed as messengers receive the commutation and extra pay as follows:

Commutation.			Extra pay per day.
Rations per day.	Fuel per month.	Quarters per month.	
$0 50	$8 00	$10 00	$0 20

Whenever a headquarters is at a military post, fuel and quarters are furnished the clerks and messengers in kind, if practicable. When furnished in kind, commutation therefor also is not paid. The several Commanders may, at their discretion, discharge any of their general-service clerks and fill the vacancies in the authorized strength of the detachment by transfers from companies or enlistments in the general service. When, however, the service of any can be dispensed with, they are discharged or transferred to companies and their places not filled.

GENERAL-SERVICE WAGON.—A wagon of ordinary construction, having a long body covered with water-proof canvas; it is fitted for double draught, and has wheels and axletrees of great strength. It will carry 1½ tons, or take 20 powder-cases.

GENERALSHIP.—The office of General; the exercise of the functions of a General; the skill and conduct of a General Officer; military skill in any Commander.

GENEVA CONVENTION.—An agreement concluded at the International Conference which was held at

Geneva, 1864, under the presidency of General Dufour, the Swiss Plenipotentiary, for the purpose of ameliorating the condition of the sick and wounded in time of war. The credit of originating this Conference must be given to two citizens of Geneva, Dunant, a physician, who published a startling account of what he had witnessed in two military hospitals on the field of Solferino, and his friend Moynier, Chairman of the Society of Public Utility, who took up the idea of "neutralizing the sick-wagons," formed associations for its agitation, and at length pressed it upon the Governments of Europe, most of which sent representatives to the Conference. The Convention was drawn up and signed by them on the 22d of August, and since then it has received the adherence of every European Power, and one Asiatic (viz., Persia). The Convention consists of ten articles, of which the last two are formal. The others provide (1) for the neutrality of ambulances and military hospitals as long as they contain any sick; (2) for that of the Staff; (3) that the neutrality of these persons shall continue after occupation of their hospitals by the enemy, so that they may stay or depart, as they choose; (4) that if they depart, they can only take their private property with them except in case of ambulances, which they may remove entire; (5) that a sick soldier in a house shall be counted a protection to it, and entitle its occupants to exemption from the quartering of troops and from part of the war requisitions; (6) that wounded men shall, when cured, be sent back to their own country on condition of not bearing arms during the rest of the war; (7) that hospitals and ambulances shall carry, in addition to the flag of their nation, a distinctive and uniform flag bearing a red cross on a white ground, and that their Staff shall wear an arm-badge of the same colors; (8) that the details shall be left to the Commanders. A second Conference was held at Geneva on the same subject in 1868, and a supplementary Convention drawn out, which, though not formally signed, has been acquiesced in by all the signatories of the original Convention, except the Pope, and which, while still unratified, was adopted provisionally by France and Germany in the War of 1870. It consists partly of the interpretations of the former Convention, and partly of an application of its principles to maritime wars. Its main provisions are these: That when a person engaged in an ambulance or hospital occupied by the enemy desires to depart, the Commander-in-Chief shall fix the time for his departure, and, when he desires to remain, that he be paid his full salary; that account shall be taken in exacting war requisitions not only of the actual lodging of wounded men, but of any display of charity towards them; that the rule which permits cured soldiers to return home on condition of not serving again shall not apply to officers, for their knowledge might be useful; that hospital-ships, merchantmen having wounded on board, and boats picking up wounded and wrecked men shall be neutral; that they shall carry the red-cross flag, and their men the red-cross armlet; the hospital-ships belonging to Government shall be painted white with a green strake, those of Aid Societies white with a red strake; that in naval wars, any strong presumption that the Convention is being abused by one of the belligerents shall give the other the right of suspending it towards that Power till the contrary is proved, and, if the presumption becomes a certainty, of suspending it to the end of the war.

GENIUS.—This word, which conveys the most lofty eulogium that can be applied to intellectual excellence, meant originally the tutelary god or demon that was anciently supposed to preside over the birth and destinies of every individual human being. The peculiarities attending the character and career of each person came thus to be attributed to the higher or lower nature of their attendant genii. Thus arose one of the meanings now attached to the word—namely, the special bent, aptitude, or faculty which any one possesses; as a genius for generalship, etc. In a military sense the term implies a natural talent or disposition to every kind of warlike employment, more than any other.

GENOUILLERE.—In fortification, a term for that part of the parapet of a battery which lies under the embrasure. The name is derived from French *genou*, knee, as representing the ordinary height of the genouillère above the platform on which the gun is worked. The height of the genouillère is regulated by that of the gun-carriage, generally from 2 to 3 feet.

GENOUILLIERES.—Small plates of iron, of various shapes, fixed by straps and buckles over the mail, in order to give an increased security to the joints at the knees. See *Armor*.

GENS.—This Latin word, to which so many important political and social meanings came to be attached, signifies, properly, a race or lineage. From it our own words—gentleman, gentility, etc., have come to us through the French *gentilhomme*, the primary meaning of which was, one who belonged to a known and recognized stock. By the Romans it was sometimes used to designate a whole community, the members of which were not necessarily connected by any known ties of blood, though some such connection was probably always taken for granted. In this sense we hear of the *Gens Latinorum, Campanorum*, etc. But it had a far more definite meaning than this in the Constitutional Law of Rome. According to Scævola, the Pontifex, those alone belonged to the same *gens*, or were "gentiles," who satisfied the four following conditions, viz.: 1. Who bore the same name; 2. Who were born of freemen; 3. Who had no slave amongst their ancestors; and 4. Who had suffered no *capitis diminutio* (reduction from a superior to an inferior condition), of which there were three degrees, maxima, media, minima. The first (maxima capitis diminutio) consisted in the reduction of a free man to the condition of a slave, and was undergone by those who refused or neglected to be registered at the census, who had been condemned to ignominious punishments, who refused to perform military service, or who had been taken prisoners by the enemy, though those of the last class, on recovering their liberty, could be reinstated in their rights of citizenship. The second degree (media capitis diminutio) consisted in the reduction of a citizen to the condition of an alien (*Latinus* or *peregrinus*), and involved, in the case of a *Latinus*, the loss of the right of legal marriage (*connubium*), but not of acquiring property (*commercium*); and in the case of the *peregrinus*, the loss of both. The third degree (minima capitis diminutio) consisted in the change of condition of a *paterfamilias* into that of a *filius familias*, either by adoption (*adrogatio*) or by legitimation. In the identity of name, some sort of approach to a common origin seems to be here implied. The gens thus consisted of many families, but all these families were supposed to be more or less nearly allied by blood—to be, as we should say, kindred. A Roman gens was thus something very nearly identical with a Celtic clan, the identity or similarity of name being always supposed to have arisen from relationship, and not from similarity of occupation, as in the case of the Smiths, Taylors, Lorimers, etc., of modern Europe. There was this peculiarity, however, about the gens which did not belong to the clan—viz., that it was possible for an individual born in it to cease to belong to it by *capitis diminutio*, or by adoption, or adrogation as it was called when the person adopted was *sui juris*. If the adoption was by a family of the same gens, the gentile name, of course, remained unchanged. In the case of a person dying intestate, his gentiles, failing nearer relatives, were his heirs, and they undertook the duties of guardianship in the like circumstances. The gens was further bound together by certain sacred rites, which were imposed on the whole of its members, and for the celebration of which it probably possessed, in common property, a *sacellum* or sacred spot, inclosed and containing an altar and the statue of the god to whom it was dedicated. According to the traditional accounts of the old Roman Constitution, the Gentes were a subdivision of the Curiæ, as the Curiæ were subdivisions of the Tribe. In this view of the matter, the original idea of the gens becomes simply that of the smallest political division, without any relation to kindred or other ties.—An excellent article on the gens by Mr. George Long, in which references to the principal German authorities on the subject are given, will be found in Smith's *Dictionary of Roman Antiquities*.

GENTILHOMMES DE LA GARDE.—A company commonly called *Au bec de Corbin*, from the battle-axe which they carried. The company went through many alterations during the Monarchy of France. During the last years of that government it consisted of 200 guards, under the command of a Captain, a Lieutenant, and an Ensign. The Captain had the power of giving away the subaltern commissions, and had, moreover, the entire management of the rest; every vacancy being in his gift. When the company was first raised its particular duty was to attend the King's person, and to be constantly near him on the day of battle.

GENTLEMEN-AT-ARMS.—The body-guard of the British Sovereign, and, with the exception of the Yeomen of the Guard, the oldest corps in the British service. It was instituted in 1509 by Henry VIII., and now consists of 1 Captain, who receives £1200 a year; 1 Lieutenant, £500; 1 Standard-bearer, £310; 1 Clerk of the Check, £120; and 40 Gentlemen, each with £70 a year. The pay is issued from the Privy Purse. Until 1861, the commissions were purchasable, as in other regiments; but by a royal command of that year purchase has been abolished in the corps, and henceforth the commissions as Gentlemen-at-Arms are to be given only to military officers of service and distinction. The attendance of the Gentlemen-at-Arms is now rarely required, except on the occasions of drawing-rooms, levées, coronations, and similar important state ceremonies. The appointment, which is in the sole gift of the Crown, on the recommendation of the Commander-in-Chief, can be held in conjunction with half-pay or retired full-pay, but not simultaneously with any appointment which might involve absence at the time of the officer's services being required by the Sovereign.

GEOGRAPHICAL DEPARTMENTS AND DIVISIONS.—In the United States, a Geographical Military Division consists of a number of Geographical Military Departments, and is usually under the command of a General Officer. Military Geographical Divisions and Departments are established and their Commanders are assigned by orders from the War Department. In time of peace, Army Corps, Divisions, or Brigades are not formed. Officers commanding Military Divisions and Departments exercise supervision and command over all the military forces of the United States within their territorial limits, whether of the Line or Staff, where special exception is not made by the War Department Subject to the approval of the General of the Army, a Division Commander regulates the establishment of military districts and posts, and originates, directs, or approves military operations within his Departments. In case of emergency, he transfers troops from one of his Departments to another requiring reinforcements. Division and Department Commanders are expected to decide all matters properly coming within their jurisdiction, or to make appropriate remarks upon such papers as they forward for decision of higher authority. A Division Commander decides cases sent him by way of appeal. Department Commanders exercise a general supervision of all military reservations within the limits of their commands, and will use force to remove squatters or trespassers when, in their judgment, it becomes necessary. See *Department Commander*, *Division Commander*, and *Military Department*.

GEOMETRICAL PROGRESSION.—A series of quantities are said to be in geometrical progression when each term of the series is equal to that which precedes it multiplied by some constant factor—i.e., some factor which is the same for all the terms; or, in other words, when the ratio of any two successive terms is the same. Thus a, ar, ar^2, ar^3. . . and 2, 6, 18, 54 . . . are geometrical series. The sum of n terms of the former series may be easily obtained. Let it be S. Then $S = a + ar + ar^2 + \ldots + ar^{n-1}$. Multiply both sides by r, we have $rS = ar + ar^2 + \ldots + ar^n$. Subtracting the former of these expressions from the latter, we have $(r - 1)S = ar^n - a$. Whence we have $S = a \cdot \frac{r^n - 1}{r - 1}$. If the series be one whose terms constantly diminish, i.e., if $r < 1$, and then if we suppose n indefinitely great, r^n will be indefinitely small, and we shall have $S = \frac{a}{1 - r}$ for the sum of the series extended *ad infinitum*. For example, the sum of the series $\frac{3}{10} + \frac{3}{10^2} + \frac{3}{10^3} + \ldots$ *ad infinitum* is $\frac{1}{3}$. It is obvious that any three of the four quantities a, r, n, S being given, the equation $S = a \cdot \frac{r^n - 1}{r - 1}$ will enable us to find the fourth. Series of this class are frequently encountered in the solutions of problems in gunnery.

GEOMETRIC CHUCK.—A chuck having a radial slider to which the work is attached, the said slider oscillating in a plane at right angles to the axis of motion, so as to produce curved lines in various patterns, as regulated by special devices. See *Chuck*.

GEOMETRY.—A science discussing and investigating the properties of definite portions of space under the fourfold division of lines, angles, surfaces, and volumes, without regard to any physical properties which they may have. It has various divisions, e.g., plane and solid geometry, analytical or algebraical geometry, descriptive geometry, and the higher geometry. Plane and solid geometry are occupied with the consideration of right lines and plane surfaces, and with the solids generated by them, as well as with the properties of the circle, and, it may be said, the sphere; while the higher geometry considers the conic sections and curved lines generally, and the bodies generated by them. In the higher geometry, immense advances have recently been made through improved methods, the application of modern analysis, and the various calculi in algebraical geometry, the nature of which is explained in the article Co-ordinates. Descriptive geometry, a division of the science, so named by Monge, is properly an extension or general application of the principle of projections, its object being to represent on two plane surfaces the elements and character of any solid figure. It has many practical applications. When one surface penetrates another, for instance, there often result from their intersection curves of double curvature, the description of which is necessary in some of the arts, as in groined vault-work, and in cutting arch-stones, etc., and this is supplied by descriptive geometry. On geometry likewise depends the theory of gunnery, mining, mechanics, hydraulics, pneumatics, etc.

GEOPHAGISM.—The custom of dirt-eating, indulged in by the lowest order of savages, but most particularly in Terra del Fuego. A kind of ferruginous clay is regularly sold for food in certain parts of Bolivia. The practice is usual among the negroes of the West Indies, and to some extent among North American Indians, while Laplanders mix clay with the flour of which they make their bread.

GEORGE.—1. The badge of the Order of the Garter, exhibiting the figure of St. George on horseback piercing the fallen dragon, which lies on a mount.

2. The banner of St. George—white with a red cross. According to Sir N. H. Nicolas, the cross of St. George was worn as a badge over the armor by every English soldier "in the fourteenth and subsequent

centuries, although the custom did not prevail at a much earlier period," to indicate that he was in the service of the Crown. On the invasion of Scotland by Richard II. in 1386 it was ordained that "everi man of what estate, condicion, or nation they be of, so that he be of oure partie, bere a signe of the armes of Saint George, large bothe before and behynde, upon parell that yf he be slayne or wounded to deth, he that hath so doon to hym shall not be putte to deth for defaulte of the crosse that he lacketh. And that non enemy do bere the same token or crosse of St. George, notwithstandyng if he be prisoner, upon payne of deth." A similar ordinance was adopted by Henry V. for the government of his army in France.

3. St. George, patron of England and Russia. His origin is extremely obscure, and the very oldest accounts of him which are extant contain a strange admixture of history and legend. He is honored both in the East and the West as a martyr, and the Greek acts of his martyrdom fix the date of his death as the persecution under Diocletian; but these acts are, by the confession even of Roman Catholic hagiologists, undoubtedly spurious. On the other hand, it is asserted that the canonization of George is one of the many errors which Protestant historians freely impute to the Roman calendar, and that the George who is thus reputed a saint and martyr is no other than the turbulent and unscrupulous Arian partisan, George of Cappadocia, whom his Arian followers revered as a saint, and imposed as such upon the credulity of their Catholic countrymen. It must be confessed, however, that the best modern authorities, Catholic and Protestant, agree in admitting the great improbability of this allegation. Heylin is of one mind in this matter with the Jesuit Papebroch, and Dean Milman adopts the arguments and agrees in the opinion of the Roman Catholic Bishop Milner. The truth is, that whatever is to be said of the early accounts of the martyrdom of George, the fact of his being honored as a martyr by the Catholic Church, of churches being dedicated to him, and of the Hellespont being called "St. George's Arm," is traced by Papebroch, by Milner, and by other writers to so early a date, and brought so immediately into contact with the times of the angry conflicts in which George of Cappadocia figured as an Arian leader, that it would be just as reasonable to believe that the Catholics of England at the present day would accept Lord George Gordon as a Catholic Saint, as to suppose that the Catholics of the East—while the tomb of Athanasius was hardly closed upon his honored relics—would accept as a sainted martyr his cruel and unscrupulous persecutor. Indeed, it cannot be doubted that the St. George of the Eastern Church is a real personage, and of an earlier date than George of Cappadocia—very probably of the date to which these acts, though otherwise false, assign him. The legend of his conflict with the dragon arose most probably out of a symbolical or allegorical representation of his contest with the pagan persecutor. As in this ancient legend St. George appears as a soldier, he was early regarded as one of the patrons of the military profession. Under this title he was honored in France as early as the sixth century; but it was not until after the Crusaders, who ascribed their success at the siege of Antioch to his intercession, returned to Europe from the Holy War, that the religious honor paid to him reached its full development. He was selected as the Patron Saint of the Republic of Genoa, and also of England. At the Council of Oxford in 1222 his feast was ordered to be kept as a National Festival. In 1330 he was made the Patron of the Order of the Garter by Edward III.; and even since the Reformation the ancient sentiment is still quite popularly maintained.

GERBE.—An ornamental fire-work, in the shape of a strong paper tube filled with a burning composition. The ends are tamped with moist plaster of Paris or clay. See *Pyrotechny*.

GERIT.—The French name of a Turkish dart about two and one half feet long. It was formerly in very common use.

GERMAN ARMY.—One of the largest Continental armies of Europe. By the Treaty of Prague, concluded between Austria and Prussia after the war of 1866, a new German Confederation was formed. A few months later Prussia concluded Conventions with States forming the new Confederation, by which they were bound to adopt any quarrel of Prussia arising out of the recent events, and to place their military strength at the absolute disposal of the Prussians. In order to insure a unity of organization, the military system of the latter was adopted by these States. And now, by the Constitution of the German Empire, bearing date the 16th of April, 1871, the land forces of all the States form a united army under the command of the Emperor. The German army thus includes the Contingents of Prussia (with Hanover), Bavaria, Saxony, Wurtemberg, Baden, and a number of other States. The military system of the German Empire is as follows, and it will be remarked how closely the French system resembles it. Every man is liable to military service, and must render such service personally, neither substitutes nor purchase of exemption being allowed. There are, however, certain social exemptions made, such as for sons of widows, supports of families, etc. The number of recruits annually raised is about 143,000 men, and the peace strength of the army is fixed at 401,659 men (one-year volunteers not included), or about 1 per cent of the population. The age of conscription is 21; the period of military service is 12 years, divided into three portions of 3, 4, and 5 years; 3 years are passed by the Conscript in a Regular Regiment, the next 4 years (on furlough) in the Reserve, and the final period of 5 years in the *Landwehr* or Second Reserve of his district. This brings the soldier to about 32 years of age. After this he is incorporated in the *Landsturm*, or service for home defense in case of war. Every young man can be called up 3 years in succession; those who are exempted in their third year are passed into the *Ersatz-Reserve*, and are free from military service, but can be called upon in time of war. In order that civil professions may not be affected by military exigencies, youths of good character and education, and who have taken university or college degrees, can qualify themselves for one year's service. These *Einjährigen Freiwilligen* (one-year volunteers) have to provide themselves with everything, viz., their accouterments, equipment, and horse, if in the cavalry. The regiments of the regular army during peace-time are, on the breaking-out of war, raised to double their number by recalling an equal number of men from the Reserve, and each reserve-man so recalled returns not merely to the same battalion, but even to the very company in which he had passed the first years of his military life. The *Landwehr* battalion is the basis of the local organization, both for recruiting and mobilization. In peace-time these battalions exist only in cadres. By this system Germany can easily place in the field an army of 1,350,000 men, not including the *Landsturm*, and has now a peace-establishment of about 428,000 voted for 7 years, including officers and volunteers, with a budget of £16,000,000. The German army is organized on the territorial system, and divided into 18 army corps, of which 13 are furnished by Prussia, including the Contingents furnished by Hanover, Schleswig-Holstein, and the minor States annexed to Prussia in 1866; 2 by Bavaria, 1 by Saxony, 1 by Wurtemberg, and 1 by Baden, and the Contingent by Alsace-Lorraine. Each *Corps d'Armée* has a district, which is formed by the Province within which it is raised, recruited, and stationed. These corps districts are subdivided into divisions and brigades, and these again into *Landwehr* battalion districts. Districts are further subdivided into company districts, of which there are from 3 to 6 to a battalion. The *Corps d'Armée* of the Guard and one furnished

by Saxony consist of 2 infantry divisions and 1 of cavalry. The others have 2 divisions, except the 11th, which has 3. Each division has 2 infantry brigades and 1 of cavalry. The Saxon and the 12th corps have 2 brigades of infantry; the cavalry of the Guard has 3, the Saxon and the 15th corps 2 brigades of cavalry each. Independently of these divisions, each corps possesses 1 or 2 battalions of Rifles (the Guards 1 of Rifles and 1 of Sharp-shooters, and the Bavarian army 10 battalions of Rifles), 1 regiment of Field-artillery, 1 regiment or battalion of Foot-artillery, 1 battalion of Pioneers, and 1 of Military Train, as well as 1 battalion *Etappen* troops, 1 of Instruction, 1 of *Gendarmerie*, belonging to the Staff or permanent army. There are 74 brigades of infantry; each brigade is composed of 2 regiments of the Line and 2 of the *Landwehr*, giving a total of 148 regiments of the line. A regiment on war-footing has 60 officers, 3000 men, 73 non-combatants, with 105 horses and 19 wagons. The regiments of infantry consist of 3 battalions, the third one being Fusiliers. Each battalion has 4 companies, and has a peace-strength of 552 of all ranks, and a war-strength of 1022. Besides these field-battalions, a fourth or depot battalion, 1240 strong, is formed on mobilization. The Rifles and Sharp-shooters (*Jäger* and *Schützen*) are not organized in regiments, but form independent battalions. They are recruited from picked men, chosen throughout the army corps district. The cavalry of the German army is divided into 38 brigades; 1 brigade is composed of 4 regiments, 15 of 3, and the 22 others of 2 regiments, giving a total of 93 regiments—12 of Cuirassiers (including those of the Guard), 34 of Dragoons, 18 of Hussars, 25 of Lancers, and 4 Saxon regiments. In peace-time these regiments consist of 5 squadrons, of 4 officers and 135 men each; in war-time they take the field with 4 squadrons of 150 each, while a fifth remains behind to form the depot. The brigades of field-artillery are generally composed each of 2 regiments, of which 1 is composed of 2 sections of 4 batteries, forming the division artillery; and the other, consisting of 2 sections of 3 batteries, and 1 section of horse-artillery of 3 batteries, forming the artillery of the *Corps d'Armée*. Each battery has 4 guns. The Foot-artillery brigade is, with few exceptions, composed of 2 battalions of 4 companies each; to these must be added 1 company of Instructors for the School of Gunnery, and 1 company for laboratory purposes. The battalions of Pioneers have each 4 companies—1 of pontons, 2 of sappers, and 1 of miners. The *Etappen* battalion, which is under the direct command of the Chief of the Staff, has also 4 companies. The peace-establishment of each company is 146 men, but on the war-footing it is increased to 218 men. Further, there are 1 Railway battalion and 13 sections of Field-telegraph. The Train is a mere skeleton on a peace-footing, and has 37 companies with a strength of 5049, which amounts to nearly 49,000 men when it takes the field. The German artillery is armed with guns of cast-steel (Krupp's system); the field-batteries have 8.8-cm. guns, and throw shrapnel weighing 17.9 lbs.; the horse-artillery have 7.85-cm. guns, throwing the same nature of shell, weighing 12.2 lbs. On war being declared, the different *Corps d'Armée* are formed into armies; and to obtain the necessary strength to place them on a war-footing, the Government calls under the Colors the yearly Contingent of Conscripts, the Reserves, and the men of the *Landwehr*. The whole army is then divided into (1) field, (2) depot, and (3) garrison troops. The field-troops of a *Corps d'Armée* comprise—(*a*) Two divisions of infantry, each having 1 regiment of cavalry and 1 detachment of artillery (24 guns). (*b*) The artillery of the *Corps d'Armée*, of 1 regiment of field-artillery, of 6 field-batteries, and 2 horse-artillery batteries. (*c*) Three independent companies of Pioneers. (*d*) *Sections of columns*, viz.: 10 columns of ammunition, 3 of pontons and train, 5 of provisions, 3 sanitary detachments, 1 remount depot, 1 column of field-batteries, 5 columns of land-transport, and 12 ambulances, the *intendance* (commissariat), field-post, etc. The other cavalry regiments, not attached to the different divisions, are formed into cavalry divisions of 2 and 3 brigades, and 3 batteries of horse-artillery. These divisions are under the immediate command of the General-in-Chief. The army is commanded by the Emperor, with a War Minister, and a Chief of the Staff under him. The War Department is divided into three principal offices, as follows: 1. Central office, including the Ministerial one. 2. General War Department, comprising organization, mobilization, quartering, training; strategical and purely military questions. 3. Military Finance Department: pay, clothing, equipment, and supply. The great General Staff of the German army is thus divided: 1. Central Bureau: general correspondence and direction of all the other sections. 2. Three sections; collect all available and latest information concerning European armies, etc., each section having a certain number of countries under its charge. 3. Railway section. 4. Military history section: historical records, histories of great wars, annals, etc. 5. Geographical statistical section, connected with the topographical section: topography and statistics of foreign nations; statistics of Germany. 5. Topographical and land triangulation: survey (land and cadastral), with special regard to military requirements. 7. Intelligence-office. 8. Map-room: store-room for original surveys, maps for distribution. There are 61 officers on the General Staff at Berlin, and they are divided into two classes: 1. Active Staff, liable to serve with corps and divisions in their turn; and 2. The *Neben-Etat*, or accessory establishment, consisting of from 30 to 40 officers noted for special acquirements, but who do not belong to the first division. There are besides 113 employés, such as registrars, draughtsmen, etc. Bavaria and other German States have similar establishments, under the supervision of the Great General Staff at Berlin. The mode of officering the German army is in two ways: 1. By candidates passing the required examination in general subjects, serving a short time in the ranks or otherwise as non-commissioned officers, and qualifying in the theoretical knowledge of their profession after a nine months' course of study at the *Kriegsschule*, or School of War. 2. By passing the latter examination direct from a special superior class of the Corps of Cadets. There is no examination for promotion to any commissioned rank in the army, promotion being obtained by relative merit. Men of ability are noticed by those in authority and promoted; those of inferior capacity do not progress. See *Army*.

GERMAN LIFE-SAVING ROCKET.—The 5-centimeter German life-saving rocket (5^{cm} Rettungsrakete) is composed essentially of a body, head, base, rocket-stick, and chain. The rocket-case or body is cylindrical, made of sheet-metal .05 inch in thickness. The head is ogival, with a shoulder that extends one fourth of an inch beyond the case, and has a cylindrical tenon to fit the front end of the rocket-case. The latter is secured to the head by screws. The inside of the rear end of the case is reinforced for 1.1 inch of its length by a cylindrical metallic ring, which serves as a seat for the screws that attach the base to the body. The base extends to the rear, forming three ribs, placed triangularly, with all the metal removed from the axial portion to facilitate the escape of gas. These ribs conjoin at their posterior ends. An axial hole is drilled through this portion, having a female-screw thread cut upon its interior surface to receive the screw on the end of the rocket-stick. When prepared and packed for service the composition is covered by a water-proof cap, from which projects a fuse, extending 2.5 inches towards the rear. The fuse is steadied in its position by a strap of laboratory-paper reaching to one of the ribs. The fuse and cap are covered with a coat of shellac varnish. Care must be taken in handling not to break off the fuse, which is more or less exposed. The rocket-stick is of wood, enveloped at the front end by a metallic frustum of a cone, whose larger base receives the end of the stick, and whose smaller base is penetrated by the shank of a screw, intended to enter in the hole in the base of the rocket. The stick, frustum, and screw-shank are bound together, and held in place by two wrought-iron bolts of small diameter. The rear end of the rocket-stick is armed with an iron loop, with flattened arms, slightly curved to fit the outside of the stick. This loop serves as the point of connection for the rocket-chain. The diameter of the rocket-stick is slightly greater in the middle than at either end. All the metallic parts of this line-carrying projectile are painted black.

The following are the principal dimensions and weights:

	Inches.	Centimeters.
Total length of 5cm life-saving rocket....	23.5	59.69
Case or body:		
Length........	15.0	38.10

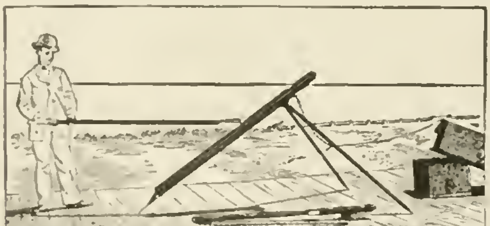
	Pounds.	Kilos.
Weight of rocket........................	10.0	4.53
Weight of rocket-stick and chain........	5.5	2.49
Total weight of rocket complete.........	15.5	7.02

The Germans also use a large 8cm life-saving rocket. The form and construction of this rocket is essentially the same as the 5cm rocket, from which it differs only in dimensions and weight. The description of the 5cm rocket will answer for this one.



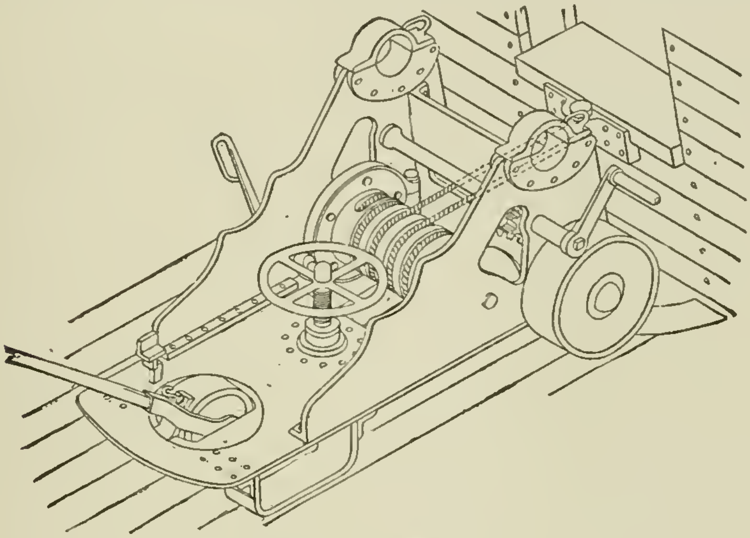
German 8cm Life-saving Rocket.

The German rocket-stand is trough-like in shape, and is supported by two legs near the front end and a curved iron foot or tang at the rear end. The trough like body of the tube is made of sheet-iron or steel, and is constructed from a single piece of metal, curved over a former of the required shape. A longitudinal slot in the bottom, 10.9 inches long and 1 inch wide, extends from the front end to the first exterior rib. This slot is for the reception of the rocket-chain, which is led along the bottom of the trough under the rocket and stick, and allowed to pass downward through this slot. The longitudinal edges of the trough are stiffened and strengthened by angle-pieces of iron running the whole length. These angle-pieces have one side riveted to the inside of the trough, forming the bearing surfaces for the rockets, and the other forming an exterior projecting flange. A rolled bar of iron, 1 inch wide and .3 inch thick, runs from the rear end of the longitudinal slot the whole length of the trough on the under side. The lower or rear end of this metallic bar projects about 10 inches beyond the frame, is decurved and pointed, to form the claw or tang for the support of this end of the trough. This is made of wood, shod at one end with a sharp-pointed steel socket, and armed at the other with a hollow brass tube, bent and split to form a hinged clamp. The latter is actuated by a lever and a spring. This staff is used to hold the *pillenlichte* for igniting the rocket-fuse. The sharp-pointed socket is for convenience in thrusting it into the ground in an upright position. If carelessly thrown aside, it is liable to be lost in the sand. The staff is painted the same color as the rocket-stand. The rocket line is made of hemp. The line is twisted, and is made with three strands, each composed of four yarns. The diameter of this line is .31 inch, or a little greater than "No. 9 Silver Lake braided cord." The rocket-line is stowed in the faking-box in the usual manner. The combined weight of the faking-box and line is 100 pounds, or 9.5 pounds greater than the United States service-box A, with a No. 9 linen line.

The following is the method of using the German rocket apparatus:

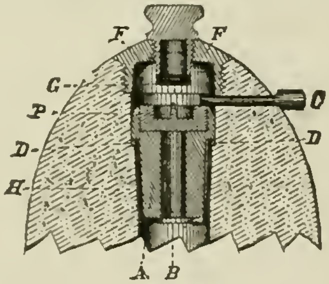
The apparatus is supposed to be at the firing-point. First remove the rocket-stand from its box, spread the legs, and place the stand with the axis of the trough pointing in the desired direction. Then give the proper elevation by raising or lowering the front end by means of the legs. A quadrant or combination-level is used to adjust the elevation. Place the faking-box several feet in front of the stand, turn it upside down, remove the frame and pins and false bottom. Incline the box to the front with its length in the direction of the line of fire, and place the false bottom or frame transversely on edge beneath the rear end of the box, to preserve the proper inclination towards the front. Then screw a rocket-stick into the base of one of the rockets, put the chain in the slot at the front end of the trough of the stand, and lead it along the bottom of the trough. Place the rocket in the trough over the chain, drawing the latter taut, and allow the end of the stick to abut against the plate at the lower end of the trough; carry the other end of the rocket-chain to the front and tie the rocket-line to the ring. The rocket is now ready to be fired. Take a *pillenlichte* and put the square end in the clamp of the firing-staff, which brings the end with the fulminating primer to the front. Next place the bell-shaped mouth of the firing-lock, with the firing-pin withdrawn, over the outer end of the *pillenlichte;* press the thumb upon the rear end of the firing-lever. This action relieves the firing-pin, the spiral spring throws it to the front, exploding the primer, which sets the composition on fire. Approach the rocket-stand, extend the firing-staff until the burning *pillenlichte* comes in contact with and ignites the fuse in the base of the rocket. After seeing that the fuse is properly ignited, stand clear of the apparatus. As soon as the fuse burns up to the base of the rocket, the composition takes fire, and the rocket, guided by the inclined trough of the stand, is launched to the front, carrying with it the stick, chain, and rocket-line. The object of the stick is to give steadiness to the flight, that of the chain to preserve the line from being burned off by the flames issuing from the rocket. See *Anchor-rocket, Life-saving Rockets, Pillenlichte,* and *Rockets.*

GERMAN NAVAL CARRIAGE.—Carriages of this kind have been recently constructed for light guns and introduced into the German naval service. They belong to the class of truck-carriages, are light, easily moved into battery, take up but little space, and are provided with a circular friction-brake, by which the recoil of the gun may be controlled at pleasure. A 6-inch gun mounted on one of these carriages was fired a number of times at Krupp's proof-grounds for test. The carriage worked well, checking the recoil within a short distance. As the principle on which the recoil is controlled may be as well used in the construction of some of the carriages for the land-service, it may not be out of place to give a short description of its leading peculiarities. The cheeks are made of thick iron plates, each cheek of a single piece, reinforced around the trunnion-holes by a semicircular plate of iron on each side of the cheek-plate, the two riveted together through the latter. The cheeks are joined together by a front and rear bottom transom and a front vertical transom of thick iron plate. The carriage is supported on two front and one rear truck-wheels, the latter being on an eccentric axle, thrown in or out of gear by the handspike projecting to the rear. When the rear wheel is not bearing, the rear end of the carriage rests on wooden bolsters, made fast to the under side of the rear bottom transom. When the carriage is in battery, two bolsters under the front ends of the cheeks rest on a traverse-circle raised slightly above the level of the platform. The shock of the discharge is thereby thrown on these bolsters, and not on the wheels and axle. In rear of the front truck-wheels there are two shafts running across the carriage, and having journal-boxes in the cheeks; the first one carries a pinion inside of the right cheek-plate and has a crank on each end, outside of the cheek; the other carries a windlass, with a cog wheel on one end and an iron drum on the other, just inside of the cheeks. The teeth of the wheel engage in those of the pinion. The drum is enveloped by a band-brake, which can be tightened by means of a screw, or within narrow limits by a lever placed on the outside of the left cheek, and held in any desired position by a pin through the lever and cheek-plate. A strong rope is made fast at its middle to the side of the vessel, or the parapet in front of the gun, and the two ends are wound around the windlass and made fast to it. A certain pressure is applied to the brake by means of the screw and lever for that purpose. When the gun is fired, the recoil of the carriage is overcome by the rope, the friction between the brake and the drum offering a certain resistance to the turning of the windlass and the unwinding of the rope. Carriages of this pattern are made in Dantzic, for the Prussian navy, by Mr. Wagenknecht, who also designed it. See *Sea-coast and Garrison Carriages*.



German Naval Carriage.

GERMAN PERCUSSION-FUSE.—In this fuse a metal plunger, A, having a central fire-hole, B, is let into the fuse-hole and rests against the shoulders, DD. Let into the top of the plunger and across its center is a metal bar, P, having a projecting point on its top side, the point being in center of fire-hole. The plunger is retained in its place by a pin, C, which passes transversely into the fuse-hole, the side of which is put in contact with the point of the cap. The outer end of the pin projects on the side of the shell, the projection being limited by the line of the cylindrical portion. The fuse-hole is closed by a screw-cap, F, having a small central screw-hole into which the fulminate cap, G, is screwed. When fired from a rifle-piece, the centrifugal force generated by the revolution of the shell throws out the pin, C; the plunger by its inertia is retained at the bottom of the chamber during the flight of the projectile; at the moment of impact the projecting point on the plunger impinges against the fulminate, which, exploding, ignites the charge in the shell.



The fulminate-cap, G, and pin, C, are not applied to the shell until the instant of loading, when the loader, who carries these articles in a pouch, screws in a fulminate-cap and inserts the pin, previously feeling that the plunger does not stick. To keep the bursting-charge in place in the shell, a brass thimble, H, with a flange about the top, and small holes in the bottom, is first pressed into the fuse-hole and takes against the shoulder, D. A piece of cloth is pasted over the fire-holes in the bottom of the thimble. In this thimble the metal plunger rests. See *Fuse*.

GERMAN STEEL.—A metal made of charcoal-iron obtained from bog-iron or the sparry carbonate. See *Steel*.

GERMAN SYSTEM OF FORTIFICATION.—In the large additions made to the fortifications of the German States since 1815, the German engineers have for the most part of these new structures adopted for the plan of their enceintes the polygonal system with flanking caponieres, combining with these numerous casemates for defense, for bomb-proof shelters, for quartering the troops and preserving the munitions and other stores. The following appear to be the leading features upon which these works are based: 1. To occupy the principal assailable points of the position to be fortified by works which shall contain within themselves all the resources for a vigorous defense by their garrisons; these works being placed in reciprocal defensive relations with each other, but so arranged that the falling of one of them into the besieger's hands will neither compel the loss of the others, nor the surrendering of the position. These are styled *independent works*. 2. To cover all the space to the rear of these independent works either by a continuous enceinte, usually of the polygonal system, with a revetted scarp of a sufficient height to secure it from escalade; the parts of this enceinte being so combined with the independent works in advance that all the approaches of the besiegers upon each, both during the near and distant defense, shall be swept in the most effective manner by their fire; or else to connect these works by long curtains; or, finally, to employ them, as in a system of detached works, either to occupy important points in advance of the main work, or for forming capacious intrenched camps with a view to the eventualities of a war. 3. To provide the most ample means for an active defense by covered-ways strongly organized with casemated redoubts, and with spacious communications between them and the interior for sorties in large bodies. 4. So to organize the artillery for the near defense that it shall be superior to that of the besiegers at the same epoch, and be placed in positions where it will be sheltered from the besieger's guns up to the time that it is to be brought into play.

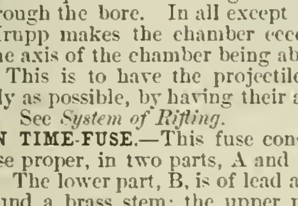
In the profiles of their works, the German engineers follow nearly the common rules for the forms and dimensions of their parapets. They employ three kinds of scarp revetments: 1. The ordinary full revetment, or sustaining wall, with counterforts. 2. Revetments with relieving arches, either with or without defensive dispositions, as circumstances may demand. 3. Scarp-walls either partly or wholly detached from the rampart and parapet. In all these cases, they give their scarp-walls a height from 27 to 30 feet for important works; and about 15 feet for those less so. The batter of these walls is usually one base to twelve perpendicular. For the full revetment with counterforts, they regulate the dimensions of both so as to afford the same stability as in the revetments of Vauban. In their revetments with simple relieving arches, they use either one or two tiers of arches; placing the single tier either near the top, or towards the middle of the wall, according to the nature of the soil and the pressure to be sustained. Revetments with relieving arches for defense, or scarp-galleries, are arranged for one or two tiers of fire. The back of the gallery is sometimes left open, the earth falling in the natural slope in the rear; or it is inclosed either with a plane or a cylindrical wall, according to the pressure to be sustained. When the upper part of the wall is detached, to form a corridor between it and the parapet in its rear, the top portion alone is, in some cases, arranged with loop-holes and arcades, or with recesses to their rear, to cover the men from shells; in others, a scarp-gallery is made below the floor of the corridor to give two tiers of fire. The corridors are from 8 to 20 feet in width; and when deemed requisite, they are divided, from distance to distance, by transverse loop holed traverse-walls for defense. When the scarp walls are entirely detached, they are arranged for either one or two tiers of fire, with arcades to cover the men; the banquette tread of the upper tier of loop-holes resting on the arches of the lower tier of arcades. The counterscarps are revetted either with the ordinary wall, or arranged with a defensive gallery with the full center arch, parallel to the face of the counterscarp-wall.

The plan of the independent works may be of any polygonal figure which is best adapted to the part assigned them in the defense of the position; but they are generally in the form of lunettes, having a revetted scarp and counterscarp to secure them from escalade. In the gorge of the work a casemated defensive barrack is placed, which serves as a redoubt or keep; a simple loop-holed wall which is flanked by the barrack closing the space between it and the flanks of the work, and securing the latter from an assault in the rear. The ditches of the work are either flanked from the enceinte in the rear; or, when the work is a detached one, by caponieres or counterscarp-galleries. The work is usually organized with a covered-way having one or more casemated redoubts, and a system of mines both for the exterior and interior defense. The defensive barrack is usually arranged for two or three tiers of covered fire, and an upper one with an ordinary parapet and terre-plein on which the guns are uncovered and destined for the distant defense. The two upper tiers of covered fire are for artillery, to sweep the interior of the work, and to reach by curvated fires the approaches on the exterior. The lower tier is loop-holed for musketry to sweep the interior. The barrack is surrounded by a narrow ditch on the interior, and this, whenever necessary, is flanked by small caponieres placed in it, which are entered from the lowest story. The barrack communicates with the interior by a door at some suitable point; and the communication between the interior of the work and the exterior is through doors in the wall inclosing the gorge. Considerable diversity is shown in the profiles of these works. They usually consist of a parapet and rampart of ordinary dimensions for the uncovered defense; of scarps either partly detached and loop-holed, with a corridor between them and the parapet; or of scarps with relieving arches arranged with loop-holes for musketry; or of a combination of these two. The height of the barrack, and the command of the parapet of the exterior work, are so determined that the masonry of the former shall be perfectly covered from the direct fire of artillery, and the exterior be perfectly swept by the artillery of the work. The portions of the counterscarps at the salients are also arranged with defensive galleries to sweep the ditches; usually with musketry, but in some cases with artillery.

Casemates are arranged for mortars in the salient angles of the work, to fire in the directions of the capitals; while one or more casemated traverses are placed on the terre-plein, to obtain a fire on the exterior and to cover the terre-plein from ricochet. The masonry of these traverses is masked by the parapet. Posterns lead from the interior of the work to the scarp-galleries, the corridors, the ditch-caponieres, and to the casemated mortar-battery in the salient. The systems of mines for the exterior defense consist simply of the listening-galleries leading outwards from the counterscarp-galleries. That for interior defense is similarly arranged; the communications with it being either from the barrack caponieres, or from the counterscarp of its ditch. The work is provided with powder-magazines which are placed at the points of the interior least exposed to the fire of the enemy; and covered guard-rooms, store-rooms for mining tools, etc., are made in connection with the posterns. The caponieres for flanking the main ditch usually consist of two faces and two casemated flank-batteries of two stories each; the lower story being loop-holed for musketry, and the upper pierced for artillery. Each battery consists of several rectangular chambers; each chamber for a single gun being 12 feet wide and 24 feet deep; or of smaller dimensions, according to the caliber of the gun and the kind of carriage on which it is mounted. The upper chambers are covered with bomb-proof arches, the lower one by arches of sufficient strength for the weight thrown upon them. The front mask-wall of the casemates is 6 feet thick; the wall in the rear is 3 feet thick, and is pierced with windows for light and ventilation. Openings for the escape of the smoke are also made in the front mask-wall immediately below the crowns of the arches. An interior court 30 feet in width is left between the two flank-batteries, and when the batteries are detached from the scarp-wall the space between is inclosed by a loop-holed wall built on each side in the prolongation of the front mask-wall. The faces of the caponiere form a salient of 60 degrees. They are separated from the flanks by two stories of arched corridors, in front of which are two arched chambers of two stories; the upper chamber being arranged for mortars. An open triangular court is left between the front walls of these chambers and the faces of the caponiere. The upper part of the walls of the faces along this court are arranged with arcades and loop-holed for musketry, and have an open corridor in their rear on the same level as the chambers of the second story. See *Polygonal System of Fortification* and *System of Fortification*.

GERMAN SYSTEM OF RIFLING.—In this system the grooves are thirty in number for all calibers, quite shallow, their sides being radial and forming sharp angles with the bore. The rifling has a uniform twist of one turn in 25 feet. The grooves are wider at the bottom of the bore than at the muzzle, so that the compression of the lead-coated projectile is gradual, and less force is expended in changing the shape of the projectile. The change of shape is effected by making the whole groove of the same size at the muzzle, and then cutting away gradually upon the loading-edge of the groove. Of course, as the twist is uniform, the driving-side of the groove cannot vary. The outer surface of the lead coating of the projectile is in raised rings with grooves between, to allow space for its being drawn down in passing through the bore. In all except his smaller calibers, Krupp makes the chamber eccentric with the bore, the axis of the chamber being above that of the bore. This is to have the projectile enter the bore as truly as possible, by having their axes nearly coincident. See *System of Rifling*.

GERMAN TIME-FUSE.—This fuse consists of the *body*, or fuse proper, in two parts, A and B, and the igniter, C. The lower part, B, is of lead and tin, and is cast around a brass stem; the upper part of this stem is provided on the inside and outside with screw-



German Time-fuse.

threads; into the inner thread is screwed the igniter, C; into the outer thread works a screw assembling-disk, which is prevented from turning when screwed down by a brass screw; at the bottom of the brass stem and projecting from its center is a sharp projecting pin. The stem has upon its exterior a grooved channel, and through it, near the point of the pin, radial holes, which permit the flame from the fulminate to communicate with the priming-chamber. The upper part, A, or the "regulator" of the fuse, is a ring of a truncated conical form; it has a priming-chamber and a circular groove on its under side, inclosing compressed mealed powder. The external opening of the chamber is covered by a thin strip of lead and tin, and the internal by a piece of paper. The rim of the "regulator" is divided into regularly-increasing spaces from 2 to 22, indicating meters and half-meters. Separating A and B is a washer of felt. A channel through the lower part of B, filled with rifle-powder, allows a communication between the burning composition of fuse and powder-charge of shell; the position of the upper opening of this channel is indicated on the rim of B by a triangular notch; the lower opening is closed by a disk of lead and tin, thin enough to be blown out by the rifle-powder. The igniter, C, is composed of four parts—the brass *stock*, which incloses all; the *screw cap*, which closes the end; the leaden-shouldered *plunger*, with its recess at bottom to receive the *fulminate wafer*. The fuse works as follows: At the instant of discharge, the plunger, by its own inertia, is forced back, shearing off the soft shoulders, and the fulminate strikes the projecting pin-point; the resulting gas escapes through the radial holes around this point and into a grooved channel, igniting the powder in the priming-chamber and circular groove, which burns till the channel of rifle-powder is reached, when the thin disk of metal at bottom of the channel is blown out, and the flame reaching the powder in the shell, explosion takes place. See *Fuse*.

GERRHES.—Shields used by the ancient Persians. They were usually made of wicker-work, and were rhomboidal in form.

GESATES.—Formerly the Gallic mercenary soldiers, who volunteered services beyond their native country. All these adventurers, or knights-errant, were called *Gesates*, either on account of the gese, or large dart, which they carried; or, as Polybius imagines, on account of the subsistence they received, which was called by that name. Also written *Gessates*.

GESES AND MATERES.—Weapons adopted by the Allobroges (a body of ancient Gauls), independently of the broad cut-and-thrust sword which the Swiss still wear. These instruments were only one cubit long; half the blade was nearly square, but it terminated in a round point which was exceedingly sharp. Not only the Romans but the Greeks received it into their armies. The former retained the full appellation and called it *gese*, but the latter corrupted it into *ysse*. The term *gese* was also applied to a sort of javelin. *Geserne* is the Anglo-Norman term for battle-axe. See *Gesates*.

GETÆ.—The people of Thracian extraction, who, when first mentioned in history, inhabited the country which is now called Bulgaria. They were a warlike people, and for a long time successfully resisted the attempts of Alexander the Great and Pyrrhus to subdue them. They afterwards removed to the north bank of the Danube, having the Dnieper as their boundary on the east, while westward they encroached on the Roman Empire, with which, from this time, they were continually at war. They were called Daci by the Romans, and their country Dacia, and are often mentioned in the literature of the Augustan Era as savage and unconquerable foes. During the reign of Domitian, they overcame the Romans, and exacted an annual tribute. But in 106, their gallant King, Decebalus, was defeated by Trajan, and the people completely subdued. A Roman Colony was settled in the country, and becoming incorporated with the Getæ, gave rise to a mixed race, the modern Wallachs.

GHENT TREATY.—A treaty between the United States and Great Britain which ended the war between the two countries known as the "War of 1812." The treaty was concluded December 24, 1814, two weeks before the battle of New Orleans. The main provisions were: 1st. Restoration of all territory, places, and possessions taken by either party from the other during the war, except certain Islands. Public property remaining in such places at time of ratifying the treaty was not to be destroyed or carried away, and the same promise was made for slaves and all private property. 2d. Article IV. provides the appointment of a Commission to decide to which of the two Powers certain Islands in and near Passamaquoddy Bay belong; and if the Commission should fail to come to a decision the subject is to be referred to some friendly Sovereign or State. 3d. Articles V. to VIII. provide for several Commissions to settle the line of boundary as described in the treaty of 1783—one Commission to settle the line from the river St. Croix to where the forty-fifth parallel cuts the river St. Lawrence (called the Iroquois or Cataraqua in the treaty); another to determine the middle of the water-communications from that point to Lake Superior; and a third to adjust the limits from "the water-communication between Lakes Huron and Superior to the most northwestern point of the Lake of the Woods." 4th. Article IX. binds both parties to use their best endeavors to abolish the slave-trade, as being "irreconcilable with the principles of humanity and justice." It is remarkable that the treaty fails to speak of the impressment of American seamen, a main cause of the war, and passes over the claims of the United States to participate in the fisheries, noticed in the treaty of 1783; nor does it conclude the question as to British and American naval forces on the northern lakes.

GHORCHANA.—The irregular Sikh yeomanry who served in the wars in the Punjab between the Sikhs and the English.

GHURRIE.—An Indian term; a circular plate of gun-metal, issued to troops in India, in the proportion of one per regiment, for the purpose of striking the hours. This kind of plate is made up in the country.

GIAMBEUX.—Greaves or an armor for the legs, made of metal or waxed leather, and much worn in the Middle Ages.

GIANT POWDER.—A mixture of nitro-glycerine with absorbents, by which this dangerously-explosive liquid is made into a perfectly safe solid substance, of a consistence and appearance not unlike light-brown sugar. It is not possible to explode this powder by ordinary accident, nor even by the application of a match. A quantity of it placed upon a rock and fired with a lighted match will burn away very much as a piece of camphor or resin would burn, with little flame but much smoke, and will boil and bubble until only a crust is left. There is not the least danger, therefore, of igniting the powder dangerously, until properly placed for the blast. In this respect it has a very great advantage over ordinary blasting-powder, which may be exploded by a spark. The powder, as it is manufactured, is made into cartridges about eight inches in length, and of any required diameter. The cartridges are wrapped in strong parchment-paper, and covered with paraffine. They are fired by a cap which is inserted into the end of the cartridge. The fuse, which is of the common kind, is inserted into the open end of the cap, which is pinched close upon it with a small pair of pliers, so as to hold it firmly. The cartridge is then opened at one end, the cap with the fuse attached inserted, and the paper is tied tightly around the fuse with a piece of twine. See *Dynamite* and *High Explosives*.

GIBERNE.—A sort of bag in which the grenadiers held their hand-grenades. It was worn like a powder-flask.

GILL COMBINATION-FUSES.—The metallic stock, A, of the fuse shown in Fig. 1 is open at both ends, the front half being bored conically to receive the time-fuse, B. At the bottom of the recess for fuse B is a small disk of metal, C, having a vent-hole, D, through its center; about one eighth of an inch below the disk C is a second and heavier one, E, having a central projecting point, F, on the under side; through this disk and equidistant from its center are three small holes. The space between disks is filled with pressed musket-powder, pieces of thin paper preventing its falling through holes in disks. The remainder of the stock, A, is bored cylindrically for the play of the triangular plunger, G, the hole through center of which is surmounted by a percussion-cap, H. On one of the triangular edges of the plunger, G, is a single stud running full length of plunger; both of the other edges have two studs, so arranged that the ones in front shall be in a different plane to insure freedom at impact. The cylindrical hole through the plunger is filled with pressed musket-powder and end stopped by a leather plug. A safety-pin secures the plunger in place. A metal pin, L, prevents the plunger from falling out, and a paper washer closes the rear end of stock. The fuse acts as follows: the time-fuse, B, cut for a certain number of seconds, is ignited at the instant of discharge by the gas from powder-charge, and the flame from fuse-composition ignites the pressed musket-powder between the disks C and E, which in turn ignites the bursting-charge of shell. Should, however, the flight of the projectile be arrested before the burning out of fuse-composition, the plunger, G, is thrown forward, the cap striking the projecting point, F, on disk E, igniting mealed powder in the center of plunger, G, thus igniting the bursting-charge and exploding the shell.

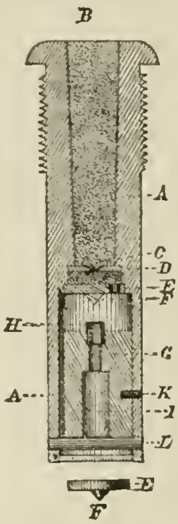


Fig. 1.

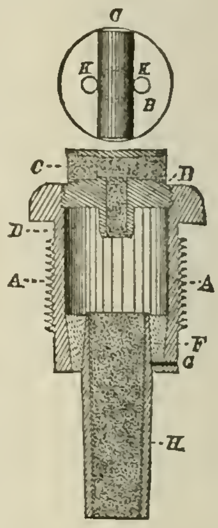

Fig. 2.

The fuse shown in Fig. 2 consists of a metal stock, A, open at the rear but closed at the front end by a screw-plug, B, having a transversal projection, C, on the out, and a central one, D, on the in side, both bored to form right-angled channels, which, when filled with pressed gunpowder, constitutes the igniter for time-fuse. At the bottom of the cylindrical pocket of the stock, A, there is a recess to receive the wedge-shaped, soft-metal valve or stopper-ring, F, which is held, after being pressed tightly into place, by two pins, G. The stock terminates in a slightly conical-shaped projection bored to receive and hold securely the time-fuse, H. The bottom of the recess for valve, F, is open, except at the three points or shoulders. The screw-plug, B, is provided also with two holes, KK, through which may be passed a strand of quick-match to insure ignition of time-fuse. The operation of the fuse is as follows: The gas from the burning powder-charge starts the igniter, which in turn ignites the time-fuse—cut as desired; should the shell's progress be arrested before burning out of fuse, the soft-metal ring is thrown forward, allowing gas from burning fuse free communication with bursting-charge in shell. See *Fuse*.

GILL DYNAMOMETER.—This instrument consists essentially of a hydraulic jack for producing pressure, and a system of levers and weights for recording same. There are two distinct methods of applying the pressure; one by hand, the other by the accumulator. Both methods involve the use of the jack; but in the first the pressure is intermittent, while in the second it is continuous. Automatic checks are arranged so as to relieve the pressure where the required effect has been produced. The combination leverage is 1 to 200. The capacity of the machine is 10,000 pounds, and any pressure up to that limit can be measured by the proper adjustment of the weights in the scale-pan and the slide on the graduated levers.

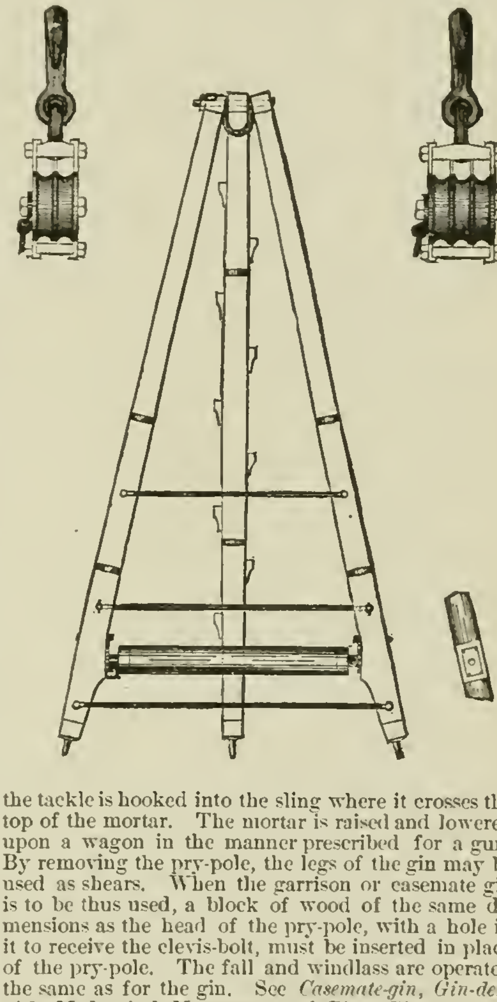
GIMBAL.—A mechanical contrivance for keeping a suspended body vertical, whatever be the derangements to which the points of suspension are liable. It consists of two brass rings which move within one another, each perpendicularly to its plane about two axes, placed at right angles to each other.

GIMLET.—A tool for boring holes in wood to receive nails, screws, etc., and generally used when the hole is to be larger than can be bored with a brad-awl. It has a conical screw-point, followed by a groove for clearing, and is fitted in a cross or T handle. An improvement has lately been made by twisting the grooved part of the gimlet, so that it forms a long spiral groove. A great variety of gimlets are used in the arsenal and laboratory.

GIN.—The gin is a tripod formed of three poles. Two of these poles, called legs, are joined together by braces of wood or iron, and contain between them the windlass. The third pole is called the pry-pole, and is joined to the legs, at the top, by a bolt. This bolt supports a clevis, to which the upper block of the tackle is hooked. The windlass is worked by two handspikes fitting into brass sockets, one at each extremity of the windlass; the operation of the handspike is made continuous by the action of a pawl attached to the socket on the ratchet of the windlass. To prevent the legs and pry-pole from sinking into the ground, or injuring the pavement of casemates, stout pieces of wood, called shoes, are placed under them. The hoisting apparatus consists of two blocks through which the fall is rove. The fall is wound two or more times around the windlass. There are three kinds of gins used for artillery purposes: the siege, the garrison, and the casemate. The last two differ from each other only in height; the first differs from the others in construction and size. Piper's gin is an improved modification of the siege-gin. When the gin is put together and raised, that part included between the legs and pry-pole is called the inside, the outside being the part without the legs; the right corresponding to the right hand of a man standing at the middle and outside of the windlass, facing towards it, the left corresponding to his left hand.

When mounting a siege-gun, it is immaterial upon which side of the piece the legs of the gin are placed, but for uniformity they are generally placed on the right. The gun is suspended either by a sling or by a bail; the latter is preferable. It consists of a stout piece of iron passing like a handle over the piece and fitting against the ends of the trunnions, to which it is fastened by iron bolts passing through the ends of the bail into holes bored for the purpose, one in the end of each trunnion. A clevis, attached to the middle of the bail, gives a place for hooking the lower block of the tackle. The piece may be conveniently slung by a rope passed around each trunnion, and the ends fastened together on top of the piece; or trunnion-rings may be used. Hook the pulley to this sling or to the trunnion-rings; bear down with one or two men on the handspike in the bore to balance the piece, and when it is raised sufficiently high run the carriage under it, and place a handspike in the trunnion-beds and a block on the stock. Lower the gun, the trunnions directly over the trunnion-beds, until the piece rests on the block and on the handspike. Remove the sling or rings from the trunnions, and run the carriage, with the gun on it, back until the head of the checks is in rear of a perpendicular let-fall from the head of the gin. Pass the sling around the chase, hook the pulley to it, and work the gin until the weight no longer bears on the handspike in the trunnion-beds; remove the handspike, and lower the trunnions to their places; bear down on the muzzle, and remove the block from under the breech

To sling and hoist a siege-mortar mounted on its carriage, a gun-sling or sling-chain is used. In either case, the middle of it is passed under the front notches; the ends carried up, and, crossing over the top of the mortar, are passed under the rear notches. The gin is erected over the mortar, and the lower block of



the tackle is hooked into the sling where it crosses the top of the mortar. The mortar is raised and lowered upon a wagon in the manner prescribed for a gun. By removing the pry-pole, the legs of the gin may be used as shears. When the garrison or casemate gin is to be thus used, a block of wood of the same dimensions as the head of the pry-pole, with a hole in it to receive the clevis-bolt, must be inserted in place of the pry-pole. The fall and windlass are operated the same as for the gin. See *Casemate-gin*, *Gin-derrick*, *Mechanical Maneuvers*, and *Piper Gin*.

GIN-DERRICK.—The garrison gin-derrick consists of two legs framed together, one pry-pole, two drums or windlasses with geared wheels, and two wagon-wheels, serving the double purpose of moving the derrick from point to point and for working the windlass. The axle passes through one of the windlasses, and can at pleasure be geared into a wheel on the other windlass. Length of legs, 254 inches; greatest width of legs, 86 inches; weight, 1725 pounds. It is hoisted by being pulled over to the front; the feet of the legs then rest on the ground, and the pry-pole is carried out over the object to be raised. The wheels are now free, and the method of operating the gin is similar to that for other gins, the power being applied to the wheels instead of to handspikes. See *Gin* and *Mechanical Maneuvers*.

GINDI.—The term applied to Turkish horsemen who perform extraordinary feats in horsemanship.

GINGAL.—A weapon used by Asiatic armies in the defense of fortresses. It may be described as a large and rude musket, which is fired from a rest. The Chinese employ it to a considerable extent. Also written *Gingaul* and *Ginjaul*.

GIONULES.—Turkish volunteer cavalry renowned for their bravery and excellent horsemanship.

GIRANDOLE.—1. In fortification, several chambers in mines connected for the defense of the place of arms of the covered-way. 2. Any firework turning upon a wheel, or any wheel whose circumference is studded with rockets.

GIRDER.—A main beam used to support joisting, walls, arches, etc. Girders may be of wood or iron, and are now very commonly made of cast-iron. They are much used in supporting the upper walls of houses, while the lower part is cut away to allow of rearrangement. Wooden girders are sometimes strengthened with iron trusses, and are then called trussed girders. Sometimes a beam is cut in two, and an iron plate inserted between the pieces, and the whole bolted together. This kind of girder is called a sandwiched beam. Girders are much used in railway and fortification works, in which case they are generally of wrought-iron. The Menai and Britannia bridges are simply very large boxed girders. The *lattice* girder is another form, in which the sides are made somewhat like wooden lattice-work.

GIRDLE.—A band of leather or of other material worn round the waist, either to confine the loose and flowing outer robes so as to allow freedom of movement, or to fasten and support the garments of the wearer. In southern Europe and in all Eastern countries the girdle was and still is an important article of dress. Among the Romans it was used to confine the tunica; and so general was the custom that the want of a girdle was regarded as strongly presumptive of idle and dissolute propensities. It also formed a part of the dress of the Greek and the Roman soldier; the phrase *cingulum deponere*, to lay aside the girdle, was as equivalent to quitting the service. It was used as now in the East to carry money in; hence *zonam perdere*, to lose one's purse. Girdles and girdle-buckles are not found in early Celtic interments, nor are they frequent in Gallo-Roman graves. But in Frankish and Burgundian graves they are almost constantly present, often ornamented with plaques of bronze or silver, and the clasps and mountings chased or inlaid with various ornamental designs, occasionally including figures of the cross, and rude representations of Scripture subjects. In later times girdles are frequently represented on brasses and monumental effigies from the twelfth to the sixteenth century. They were either of leather or of woven materials, often of silk and adorned with gold and gems. The mode in which they were worn is shown on the effigies; usually fastened by a buckle in front, the long free end of the girdle was carried up underneath and then down over the cincture, and through the loop thus formed the ornamented end hung down in front.

GIRL.—A term in Heraldry, used to signify the young of the roe in its second year. See *Heraldry*.

GIROLAMO MAGGI SYSTEM OF FORTIFICATION.—A system in which the bastions are small, and provided with double flanks. The curtain has four double flanks. Vauban borrowed from this system the curtain of his third system. See *Fortification*.

GIRONDISTS.—The name given during the French Revolution to the moderate Republican Party. When the Legislative Assembly met in October, 1791, the Gironde Department chose for its Representatives the advocates Vergniaud, Guadet, Gensonné, Grangeneuve, and a young merchant named Ducos, all of whom soon acquired great influence by their rhetorical talents and political principles, which were derived from a rather hazy notion of Grecian republicanism. They were joined by Brissot's party and the adherents of Roland, as well as by several leaders of the Center, such as Condorcet, Fauchet, Lasource, Isnard, and Henri La Rivière, and for some time had a parliamentary majority. They first directed their efforts against the reactionary policy of the Court, and the King saw himself compelled to select the more moderate of the party, Roland, Dumouriez, Clavière, and Servan, to be Ministers. Ultimately, however, he dismissed them, a measure which led to the Insurrection of the 20th June, 1792. The encroachments of the populace, and the rise of the Jacobin leaders, compelled the Girondists to assume a conservative attitude; but though their eloquence still prevailed in the Assembly, their popularity and power out of doors were wholly gone, and they were quite unable to prevent such hideous crimes as the September massacres. The principal things which they *attempted* to do after this—for they never succeeded in accomplishing anything—were to procure the arrestment of the leaders of the September massacres, Danton, etc.; to overawe the mob of Paris by a guard selected from all the Departments of France; to save the King's life by the absurdest of all possible means, viz., by first voting his death, and then by intending to appeal to the Nation; and, finally, to impeach Marat, who, in turn, induced the various sections of Paris to demand their expulsion from the Assembly and their arrestment. This demand, backed up as it was by one hundred and seventy pieces of artillery under the disposal of Henriot, leader of the Sans-culottes, could not be resisted; thirty of the Girondists were arrested on a motion of Couthon, but the majority had escaped to the Provinces. In the Departments of Eure, Calvados, and all through Brittany, the people rose in their defense, and, under the command of General Wimpfen, formed the so-called *Federalist Army*, which was to rescue the Republic from the hands of the Parisian populace. Movements for the cause of the Girondists took place likewise at Lyons, Marseilles, and Bordeaux. The progress of the Insurrection was, however, stopped by the activity of the Convention. On the 20th July the Revolutionary Army took possession of Caen, the chief station of the insurgents, whereupon the Deputies of the Convention, at the head of the Sans-culottes, forced their way into the other towns, and commenced a fearful retribution. On the 1st October, 1793, the prisoners were accused before the Convention by Amar, as the mouthpiece of the Committee of Public Safety, of conspiring against the Republic with Louis XVI., the Royalists, the Duke of Orleans, Lafayette, and Pitt, and it was decreed that they should be brought before the Revolutionary Tribunal. On the 24th their trial commenced. The accusers were such men as Chabot, Hébert, and Fabre d'Eglantine. The Girondists, however, defended themselves so effectually that the Convention on the 30th was obliged to come forward and decree the closing of the investigation. That very night Brissot, Vergniaud, Gensonné, Ducos, Fonfrède, Lacaze, Lasource, Valazé, Sillery, Fauchet, Duperret, Carra, Lehardy, Duchâtel, Gardien, Boileau, Beauvais, Vigée, Duprat, Mainvielle, and Antiboul were sentenced to death, and, with the exception of Valazé, who stabbed himself on hearing his sentence pronounced, all perished by the guillotine. On their way to the Place de Grève, in the true spirit of French republicanism, they sang the *Marseillaise*. Coustard, Manuel, Cussy, Noel, Kersaint, Rabaut St. Etienne, Bernard, and Mazuyer were likewise afterward guillotined. Biroteau, Grangeneuve, Guadet, Salles, and Barbaroux ascended the scaffold at Bordeaux; Lidon and Chambon, at Brives; Valady, at Périgueux; Dechézeau, at Rochelle. Rebecqui drowned himself at Marseilles, Pétion and Buzot stabbed themselves, and Condorcet poisoned himself. Sixteen months later, after the fall of the Terrorists, the outlawed members, including the Girondists Lanjuinais, Defermon, Pontécoulant, Louvet, Isnard, and La Rivière, again appeared in the Convention. A rather flattering picture of the party has been drawn by Lamartine, in his *Histoire des Girondins*.

GIRONNE—GYRONNE—GYRONNY.—Terms used in Heraldry to indicate that the field is divided into six, eight, or more triangular portions, of different tinctures, the points of the triangles all meeting in the center of the shield. Nisbet objects to this as a vulgar mode of blazoning; and, in speaking of the "paternal ensign of the ancient surname of Campbell," he says that it is "composed of the four principal partition-lines, parti, coupé, traunché, taillé, which divide the field into eight gironal segments, ordinarily blazoned with us, girony of eight, or, and sable." The triangle in dexter-chief has been called a giron or gyron.

GIRTH.—A band or strap made of web passing round the belly of a horse or other animal, to keep the saddle in its place. There is a girth known as the *Australian girth*, which is made of a network of hide or cord. It is very much approved of in the German army, and has been adopted by the cavalry of that Nation. It never gets saturated with sweat, and is therefore less likely to get stiff and hard, and hence causes fewer girth-galls. The term *girth* is also used with reference to the circumference of timber, etc.

GISARME.—This weapon is quite different from the *war-scythe* and *breach-knife*, as it is double-edged, like the cut-and-thrust sword, and armed with hooks. Its origin dates from the Age of Bronze among the Keltic and Germanic Nations, at which time many tribes were in the habit of fastening glaives or scramas-axe swords to very long shafts. Frequently called *glaive-gisarme*. See *Guisarme*.

GISTES.—Pieces of wood which are made use of in the construction of platforms to batteries, and upon which the madriers or broad planks are placed.

GLACIS.—In fortification, the slope of earth, commonly turfed, which inclines from the covered-way towards the country. Its object is to bring assailants, as they approach, into a conspicuous line of fire from the parapet of the fortress, and also to mask the general works of the place.

In the fortifications like Noizet's, one principle is chiefly to be attended to in disposing the different planes of the glacis. They should all be swept by the artillery-fire of the works immediately in their rear, and by the musketry-fire at least of the bastion-face. The glacis of the bastion covered-way should be swept by the artillery of the bastion-face. The glacis of the re-entering place-of-arms should be swept by the fire from its redoubt. The glacis of the demi-lune offers more difficulty in its arrangement, owing to the crémaillère form of the interior crests. The best method seems the following: Planes are passed through each long branch, so as to be swept by the artillery-fire of a portion of the face of the demi-lune; these are connected by another series of planes, which are passed through the salient point of each crotchet, and below the plane of musketry-fire of at least one half of the bastion-face, and that of artillery-fire of a part of the demi-lune face. It will be readily seen, from the nature of this problem, that it admits of many solutions. In selecting amongst them, the following considerations may serve as guides: 1. When the planes of the glacis have a very gentle slope, they are better seen by the works in their rear; but the construction is more expensive, on account of the greater quantity of embankment. 2. When the slope is more steep, the enemy's works on the glacis are better exposed to the reverse views of the collateral works, although not so well seen by those directly in rear of the glacis; but the quantity of embankment is smaller. See *Fortification*.

GLADIATOR.—In antiquity, from *gladius*, a sword, one who fought in the arena, at the Amphitheater at Rome, and in other cities, for the amusement of the public. The gladiators were generally slaves, bought and trained for the purpose, by masters who made this their business. The custom is supposed to have been borrowed from the East, and to have had its origin in the practice of human sacrifices, or that of taking the lives of captives or prisoners of war, in honor of heroes who had died in battle. Thus, in the *Iliad* we read that Achilles sacrificed twelve Trojan prisoners to the manes of his friend Patroclus, and Virgil speaks of captives sent to Evander, to be sacrificed at the funeral of his son Pallas. The "Great Custom" of the King of Dahomey thus finds warrant in classic antiquity; and the North American Indians, in putting their prisoners to death with tortures, have only refined upon an ancient barbarism. After a time, all funerals were solemnized by human sacrifices, which took the form of combats, in which, to increase the interest of the spectators, the prisoners were required to sacrifice each other; and as prisoners, and afterwards other slaves, were kept for this purpose, they were trained to fight with skill and courage, to make the spectacle more impressive. These contests first took place at funerals, but afterwards in the Amphitheater; and in process of time, instead of a funeral rite, became a common amusement. The first we read of in Roman history was the show of a contest of three pairs of gladiators, given by Marcus and Decius Brutus, on the death of their father, in the year of Rome 490. In the year 537 a show of twenty-two pairs was given in the Forum. In 547 the first Africanus diverted his army at New Carthage with a gladiatorial exhibition. The fashion now rapidly increased. Magistrates, public officers, candidates for the popular suffrages, gave shows to the people, which consisted chiefly of these bloody and generally mortal encounters. The Emperors exceeded all others in the extent and magnificence of these cruel spectacles. Julius Cæsar gave a show of 320 couples; Titus gave a show of gladiators, wild beasts, and sea-fights for 100 days; Trajan gave a show of 123 days, in which 2000 men fought with and killed each other, or fought with wild beasts for the amusement of the 70,000 Romans, Patricians and Plebeians, the highest ladies and the lowest rabble, assembled in the Colosseum. A vast number of slaves from all parts of the world were kept in Rome, and trained for these exhibitions. There were so many at the time of Catiline's Conspiracy, that they were thought dangerous to the public safety, and it was proposed to distribute them among the distant garrisons. Efforts were made to limit the number of gladiators, and diminish the frequency of these shows. Cicero proposed a law, that no man should give one for two years before becoming a candidate for office. The Emperor Augustus forbade more than two shows in a year, or that one should be given by a man worth less than half a million sesterces; but it was difficult to restrain what had become a passion, and men even had such contests for the amusement of their guests at ordinary feasts. These shows were announced by show-bills and pictures, like the plays of our theaters. The gladiators were trained and sworn to fight to the death If they showed cowardice, they were killed with tortures. They fought at first with wooden swords, and then with steel. When one of the combatants was disarmed, or upon the ground, the victor looked to the Emperor, if present, or to the people, for the signal of death; if they raised their thumbs, his life was spared; if they turned them down, he executed the fatal mandate. A gladiator who had conquered was rewarded with a branch of palm, and sometimes with his freedom. Though the gladiators at first were slaves, freemen afterwards entered the profession, and even knights. Senators and knights fought in the shows of Nero, and women in those of Domitian. The Emperor Constantine prohibited the contests of gladiators, 325 A.D.; but they could not at once be abolished. In the reign of Honorius, Telemachus went into the arena to stop the fight, when the people stoned him. They were finally abolished by Theodoric, 500 A.D.

GLADIUS.—A Roman sword with a single cutting edge, and having a grooved blade. See *Gladiator*.

GLANDERS.—A malignant disease of the equine species, characterized by the appearance within the nostrils of little holes or ulcers, remarkable for their rugged, inflamed, undermined edges, their discharge of sticky, greenish, unhealthy pus, their tendency to spread, and their resistance of treatment. The blood of glanderous subjects is deficient in red globules, contains an excess of albumen and fibrine, and in this vitiated and deteriorated state is inadequate properly to nourish the body, which consequently becomes weak and wasted. The mucous membranes are also irritable and badly nourished; there is consequently impaired respiration, an obstinate choking cough, and relaxed bowels. The lymphatic glands and vessels become inflamed, and in their swollen state may be distinctly felt about the throat and underneath the jaws, and also in the limbs, where they frequently run on to ulceration, constituting farcy. Glanders is produced by any cause which interferes with the purity or integrity of the horse's blood, or produces a deteriorated or depraved state of his system. It has been frequently developed in healthy animals by their breathing for a short time a close, impure atmosphere, and cases of this sort were thus produced amongst the horses of several cavalry regiments, whilst being transported in badly-constructed, overcrowded vessels to the Crimea in 1854. Confined, overcrowded, badly ventilated stables are almost equally injurious, for they prevent the perfect aëration of the blood, and the prompt removal of its organic impurities. Bad feeding, hard work, and such reducing diseases as diabetes and influenza also rank amongst the causes of glanders. A small portion of the nasal discharge from a glandered horse coming in contact with the abraded skin of man, communicates the loathsome and fatal disease from which so many attendants of horses have died, and Government very properly compels the immediate destruction of every glandered horse. Whilst oxen and dogs are exempt from it, donkeys suffer generally in the acute form, often dying in eight or ten days. Horses frequently have it in a chronic form, and if well fed and managed sometimes live and work for years. In the old coaching-days some stages were known to be worked by a glandered team, but no animal with glanderous ulcers or discharge should on any account be preserved, for, besides being perfectly incurable, the fatal disease is communicable not only to healthy horses, but also to human beings. See *Veterinary Art*.

GLAIRE.—A broad-sword or falchion fixed upon a pike. The name is sometimes applied to the weapon used in the days of knighthood, and to that used for executions.

GLAIVE.—A modified form of the *war-scythe*. The blade of the weapon curves from the edge and has a hook or spur at its base. The point is double-edged. The glaive was much used in France during the fourteenth century, and is especially mentioned in the poem of the "Trente." Also written *Glare*.

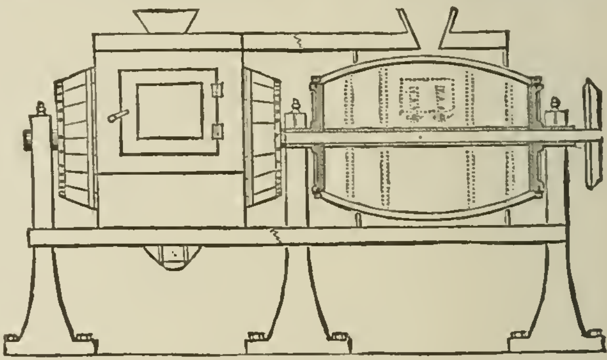
GLAIVE-GISARME.—This weapon, which British authors usually confound with the halberd, is simply a *glaire* fixed on a shaft, or a *gisarme*. See *Gisarme*.

GLAIZE.—A kind of halberd, much used by the Saxons in early times, and by whom so called.

GLASSER SYSTEM OF FORTIFICATION.—A system having a bastioned enceinte, ravelins with reduits, counter-guards, envelope, and re-entering places-of-arms with reduits. The ramparts have a demi-revetment with a chemin-des-rondes or fausse braye on the level of the ground. On the capitals of bastions and ravelins are casemated caponieres, which are well covered and powerfully defend the ditches.

GLASS-PAPER.—A polishing material made by powdering glass more or less finely, and sprinkling it over paper or calico still wet with a coat of thin glue; the powdered glass adheres as it dries. Glass-paper is very extensively employed as a means for polishing metal and wood-work; it is sold in sheets, and is very largely manufactured at Birmingham and other places.

GLAZING-BARREL.—Some manufacturers glaze or polish large-grain powder by using a small quantity of black-lead, about half an ounce to every 100 pounds of powder. The black-lead, with the powder in these proportions, is put into a glazing-barrel, and from three quarters of an hour to one hour is found to be sufficient time to polish the grain. Black-lead is also sometimes used with the small or fine-grain powder; but, although its use has some advantages, such as lessening the formation of dust, and also preventing the moisture in the atmosphere from affecting the powder so readily, still it is an impurity, and as such should be used sparingly and with much caution. Recently plumbago has been used for glazing gunpowder, and if obtained pure is preferred to black-lead, inasmuch that while a little more than half the quantity is sufficient to give a perfect glaze to the powder, it is found to protect it more effectually from the action of moisture in the atmosphere. The glazing apparatus consists of a large strong wooden barrel supported, as shown in the drawing, on an iron shaft which runs through the center. The barrels, two of which are generally placed in line on one shaft, are formed of oak, and are about 5 feet long and 2½ in diameter; the shaft is cased with wood where it passes through the barrels. Each barrel is provided with a small square door for charging and uncharging. The barrels are found to be peculiarly well



Glazing Apparatus.

adapted for the purpose, owing to their shape. Formerly wooden cylinders with straight sides were used, but it was found that the different sizes of grain had a tendency to separate in them, so that all did not receive an equal amount of polishing. But in the barrels, which are larger in diameter at the center, there is a constant intermingling of the grain and a more uniform action. A set of glazing-barrels consists of four, each pair being supported on a shaft. These shafts are of wrought-iron, covered on the inside of the barrels with wood, and receive their motion by means of bevel gearing direct from a main shaft driven by the water-wheel or steam-engine. The barrels are inclosed in wooden casings, with feeding-hoppers on the top. Into each hopper four casks of fine-grain powder (each cask containing 100 pounds) are emptied, the barrels are turned with their doors uppermost, and the contents of the hoppers pass into them; the doors are then closed and secured. The apparatus is now set in motion, and after running for five or six hours it will be found that a fine gloss has been imparted to the powder by the mere friction of the grains rubbing one against the other, whilst at the same time all the sharp angles and corners are rubbed off, and the powder thereby rendered much better for keeping or for transport. Each pair of barrels can be stopped or put in motion at pleasure, independently of the others, by simply throwing a clutch in or out of gear, so that after the barrels have been at work a sufficient time this clutch is thrown out, and they are brought to rest with their doors downwards. Upon these being unfastened and opened, the powder is delivered into casks already placed for its reception. This operation, as may be imagined, produces a small quantity of dust, which is removed by passing the glazed powder once through a slope-reel kept expressly for the purpose. The fine-grain powder is now in the same state as the large-grain powder. Both contain about the same degree of moisture, which it is necessary to extract before the powder is complete and fit for sending into store; this is effected in the drying-stove, where both the fine and large-grain powder can be dried at one and the same time. See *Gunpowder*.

GLISSADE.—The term formerly applied to the forward or backward movement of the pike.

GLOBE OF COMPRESSION.—The phrase *common mine* is applied to the crater when its radius is equal to the line of least resistance. When the crater radius is greater than the line of least resistance, the terms *overcharged mine* and *globe of compression* are used. When the crater radius is less than the line of least resistance, the mine is termed *undercharged*.

GLOBE-SIGHT.—A form of front sight used mostly on target and sporting rifles. It consists of a pin with

Globe-sights.

a small ball on the end of it, or a disk with a hole in it. For protection it is set in a tube open at both ends. The sight, with interchangeable disk, is represented in the drawing. See *Front Sight*.

GLOIRE.—An artificial fire-work of great splendor which resembles a large sun.

GLORIOUS VIRGIN.—An Order of Knighthood in Venice, founded by Bartholomew of Vicenza, and approved by Pope Urban IV. in 1262. This institution was ecclesiastical as well as military, and its objects were the protection of widows and orphans, and the furtherance of the peace of Italy. The badge was a purple cross between certain stars, and the costume a white surcoat on a russet cloak.

An Order of Knighthood of St. Mary the Glorious also existed in Rome about the seventeenth century, whose purpose was the suppression of the Barbary Corsairs who infested the Mediterranean.

GLORY.—The honor, reputation, and fame acquired by military achievements. That precarious splendor which plays around the brows of a warrior, and has been collected by hard service, extraordinary genius, and unblemished integrity; but which may desert the greatest hero through one unfortunate failure, occasioned by the fatality of human imperfection.

GLOVES.—Covers for the hands, or for the hands and wrists, having a separate sheath for each finger. Gloves are worn by all officers and soldiers when under arms or when wearing side-arms. In the United States army they are prescribed as follows: *For General Officers, Officers of the General Staff, and Staff Corps.*—Buff or white gauntlets or gloves. *For Field Officers of Artillery, Cavalry, and Infantry; for the Officers of Light Artillery and Cavalry.*—White gauntlets or gloves. All other officers and enlisted men, white gloves. *To throw the glove* is the old expression which formerly meant to challenge to single combat.

GLUE.—An impure desiccated gelatine, procured from various sources, such as the scraps of ox and other thick hides, the débris of tan-yards, the tendons and intestines of many animals, rabbit-skins deprived of their fur, scraps of parchment, old gloves, and many other apparently worse than useless matters, all contributing their portion in the manufacture of "glue." Glue is an invaluable article in the laboratory and arsenal. It differs only from *gelatine* in the care taken in its manufacture, and in the selection of the materials from which it is made; almost every animal substance will yield it, hence all kinds of animal refuse find their way to the glue-makers' boilers. Nevertheless, the impossibility of preserving for any length of time the materials required for this manufacture renders it necessary to adopt some system in choosing and preserving them, until sufficient quantities are collected, without fermentation or decomposition. Hence the refuse of tanneries, consisting of the clippings of hides, hoofs, ear and tail pieces of ox, calf, and sheep, are preferred, because they can be dressed with lime, which removes all the hair and acts like an antiseptic. For this purpose they are placed in tanks with quicklime and water for two or three weeks, during which the lime is several times renewed, and the pieces frequently turned over. They are afterwards washed and dried, and are ready for use by the glue-maker, who usually gives them another slight lime-dressing, and subsequently washes them; they are afterwards exposed to the action of the air for a while, to neutralize the caustic lime. When well drained, the pieces are placed in flat-bottomed copper boilers, which have a perforated false bottom placed a little distance above the true one, to prevent the burning of the materials, and which have been supplied with rain or other soft water up to two thirds the depth of the boiler, the pieces being piled up to some height above the top of the open boiler. The whole is kept at a gentle boiling heat until all the gelatinous part has dissolved out, and the mass of material has sunk down into the fluid. The boiling is sustained until, by repeated trials of small quantities, the operator knows the fluid is of the right consistency, when it is drawn off carefully into the congealing boxes, and fresh materials are added to the residue left behind in the boiler, and the process is repeated.

Besides its use in joinery, in cabinet-making, and similar operations, glue is used by paper-makers and in dressing silks; and for these last two purposes fine light-colored kinds in thin cakes are made. Large quantities are employed also for sizing walls in the state called *size*, which is the glue simply gelatinized after boiling in the first process. A very fine and pure white *size* is made by the bonnet-makers of Bedfordshire and other places of the skins of calves' head, ears, and the under part of the neck and belly; this is employed for stiffening straw, cotton, horse-hair, and other plaits for making bonnets and hats.

GLYACYLINE.—An explosive substance composed principally of gun-cotton and nitro-glycerine. See *Nitro-glycerine*.

GNOMON.—The hand of a sun-dial. It is placed at such an inclination with the plate of the dial that, when properly set, the gnomon will be directed to the north pole of the heavens, and its shadow will fall upon the same lines of the dial at the same hours, whatever be the season of the year—that is, for one particular latitude; but dials must be differently constructed for places which have different latitudes. It is shown in Astronomy that the elevation of the celestial pole is equal to the latitude of the place, and, consequently, the inclination of the gnomon of a sun-dial must be also equal to the latitude of the place where the dial is intended to be set. It follows, therefore, that a dial constructed for London would not be suitable for Edinburgh.

GOAT'S-FOOT CROSS-BOW.—A form of cross-bow anciently used by the cavalry. It was much lighter than the infantry cross-bow, and the string was always stretched by means of a simple lever, called a *goat's foot*.

GOBILLE.—A small copper ball, one fourth of an inch in diameter, several of which are put into a revolving cask for the purpose of more intimately incorporating the ingredients of powder, carcass, and rocket-composition.

GOBISSON.—A quilted and padded dress worn under the habergeon. Also written *Gambasson*.

GOBONY.—A term in Heraldry, the same as *componé*. A gobonated bordure is frequently carried in place of the baton sinister, not only by the lawful issue of bastards, who, after the third lawful generation, are considered entitled to make the change, but by bastards themselves. See *Bastard Bar*.

GOD SAVE THE QUEEN.—The national anthem of Great Britain, and by adoption that of several of the German States, and which is played and sung in every part of the British Empire alike on solemn and festive occasions, has been a subject of controversy with respect to its origin. Its words are apparently imitated from the Domine Salvum of the Catholic Church Service. In England the authorship has been generally attributed to Dr. John Bull, born 1563; in 1591 Organist in Queen Elizabeth's Chapel; 1596, Professor of Music in Gresham College, and Chamber-musician of James I. About the period of the discovery of the Gunpowder Plot, Bull composed and played on a small organ before the King an ode beginning with the words, "God save great James our King." He died at Lübeck, 1622. It does not appear, however, that this or any other old composition of a similar title had any connection with that which we now possess. The words and music were composed in honor of a birthday of George II., and performed for the first time at a dinner given on that occasion in 1740 by the Mercers' Company of London. The words and music were first published in the *Harmonia Anglicana*, 1742, and appeared in the *Gentleman's Magazine*, 1745. The air, according to Dr. Arne, has preserved its original form, but its harmonies have been modified by various artists; and the words were changed on the accession of William IV., and on that of Queen Victoria.

GOLADAR.—An East Indian term signifying a sutler or store-keeper. Also written *Goldar*.

GOLANDAAZEE.—The Indian term for an artilleryman. Also written *Golandanzee* and *Golundanzee*.

GOLD-BEATER'S SKIN.—The prepared external membrane of the large intestine of the ox, frequently used to protect primings and fuse-compositions from dampness, as in the construction of the Breithaupt fuse.

GOLD-COAST CORPS.—A corps in the British service made up of drilled Africans, and officered from the West India regiments. It is kept up for the purpose of protecting the possessions of Sierra Leone and Gambia.

GOLDEN EAGLE.—The typical eagle and imperial emblem of ancient Rome and Persia. It is generally of brown color, and about 3 feet long.

GOLDEN FLEECE.—In Greek tradition, the fleece of the ram Chrysomallus, the recovery of which was the object of the Argonautic expedition. The Golden Fleece has given its name to a celebrated Order of Knighthood in Austria and Spain, founded by Philip III., Duke of Burgundy and the Netherlands, at Bruges, on the 10th January, 1429, on the occasion of his marriage with Isabella, daughter of King John I. of Portugal. This Order was instituted for the protection of the Church, and the fleece was probably assumed for its emblem, as much from being the material of the staple manufacture of the Low Countries as from its connection with heroic times. The founder made himself Grand-Master of the Order, a dignity appointed to descend to his successors; and the number of Knights, at first limited to 24, was subsequently increased. After the death of Charles V., the Burgundo-Spanish line of the House of Austria remained in possession of the Order; but at the close of the Spanish War of Succession, the Emperor, Charles VI., laid claim to it in virtue of his possession of the Netherlands, and taking with him the archives of the Order, celebrated its inauguration with great magnificence at Vienna in 1713. Philip V. of Spain contested the claim of Charles; and the dispute, several times renewed, was at last tacitly adjusted by the introduction of the Order in both countries. The insignia are the golden fleece hanging from a gold and blue enameled flintstone emitting flames, and borne in its turn by a ray of fire. On the enameled obverse is inscribed *Pretium laborum non vile*. The decoration was originally suspended from a chain of alternate firestones and rays, for which Charles V. allowed a red ribbon to be substituted, and the chain is now worn only by the Grand-Master. The Spanish decoration differs slightly from the Austrian. The costume consists of a long robe of deep red velvet, lined with white taffetas, and a long mantle of purple velvet lined with white satin, and richly trimmed with embroidery containing firestones and steels emitting flames and sparks. On the hem, which is of white satin, is embroidered in gold, *Je l'ay empris*. There is also a cap of purple velvet embroidered in gold, with a hood, and the shoes and stockings are red. In Austria, the Emperor may now create any number of Knights of the Golden Fleece from the old nobility; when Protestants, the Pope's consent is required. In Spain, Princes, Grandees, and personages of peculiar merit are alone eligible.

GOLDEN HORDE.—A force of Tartars who invaded Kiev and Moscow, destroyed several other cities, and in 1241 massacred a Magyar army. Their first leader was the grandson of Genghis Khan. At the battle of Bielawisch, in 1481, they were destroyed by Ivan III. and the Nogay Tartars.

GOLD RAIN.—An ornament for rockets formed of small stars, all of the same size. These stars are cubes, the length of the side being .5 inch. The composition consists of 16 parts of niter, 10 parts of sulphur, 4 parts of mealed powder, 3 parts of lamp-black, 1 part of flowers of zinc, and 1 part of gum arabic. The sodium nitrate may be replaced by the bicarbonate of soda or the oxalate of soda. The copper sulphate is well ammoniated. See *Compositions* and *Fire-works*.

GOLD STICK.—Superior Officers in the English body-guard, and Captains in the Corps of Gentlemen-at-Arms; so called because on state occasions they carry a gilded bâton.

GOLLETTE.—A shirt of mail worn by foot-soldiers in ancient times. See *Armor* and *Hauberk*.

GOMER CHAMBER.—This chamber, named after its inventor, consists of the frustum of a cone connected with the bore by a portion of the surface of a sphere. This kind of chamber is considered very advantageous for mortars. Being large at the mouth, it allows the powder to act on an entire hemisphere of the projectile, and no risk is run of breaking it. It, however, gives a less range than either the cylindrical or spherical, but its capacity is greater.

GONFALON.—1. One of the arms borne by the Normans in the eleventh century. It was a spear, sometimes ornamented with a small flag, fixed just below the metal point, and similar to the present English lance.—2. An ensign or standard.

GONFALONIER.—A Turkish General and Standard-keeper who always precedes the Grand Seignior during war.

GONG.—An Indian instrument of percussion, made of a mixture of metals (78 to 80 parts of copper, and 22 to 20 parts of tin), and shaped into a basin-like form, flat and large, with a rim a few inches deep. The sound of the gong is produced by striking it, while hung by the rim, with a wooden mallet, which puts the metal into an extraordinary state of vibration, and produces a loud, piercing sound. It is used by the Chinese as an instrument of martial music.

GONGWALLAS.—A term applied to the Militia in India. It is thus called from *Gong*, a village, and *Wallas*, a man.

GOOD-CONDUCT BADGES.—Marks of distinction for good conduct which are bestowed upon soldiers in the English army. Each badge carries with it a reward of a penny a day. The badges are worn by soldiers below the elbow, with the points up.

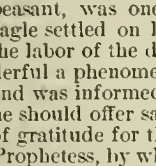
GOOD-CONDUCT PAY.—A reward of additional pay to corporals and private soldiers for good conduct. It is granted under the following circumstances: A soldier whose name does not appear in the regimental defaulter-book for at least two years preceding his claim receives—after 2 years, 1*d.* per diem, with one good-conduct badge; after 6 years, 2*d.* per diem, with one additional badge for each penny: after 12 years, 3*d.* per diem; after 18 years, 4*d.* per diem; after 23 years, 5*d.* per diem; after 28 years, 6*d.* per diem. A soldier of 16 and less than 18 years' service, and whose name has not been entered in the regimental defaulter-book for 14 years next preceding the date at which he shall become entitled thereto, shall receive the rate granted by Article 911 of the Warrant, after 18 years' service, on completion of such 14 years' continuous good conduct; and shall receive the rate attached to 23 and 28 years after 21 and 26 years respectively. The Warrant further states that a soldier shall not be advanced to a higher rate of good-conduct pay unless he shall have been in the uninterrupted receipt of the next lower rate for the two years immediately preceding his claim. But this condition shall not apply to the accelerated rates specified in Article 914. Non-commissioned officers do not receive good-conduct pay, but receive instead 2*d.* a day as an increase to their regular pay. They receive, as well, rewards for distinguished or meritorious services, annuities and medals, either while serving or after discharge. A Warrant, dated May 29, 1875, has been issued by the Secretary of War, revising the regulations contained in the Warrant of December 27, 1870, relative to the forfeiture of the service of soldiers, and to amend in certain respects the regulations relative to good-conduct pay.

GOOD-SERVICE PENSION.—An annuity of £100 a year given to General or Field Officers in the English army as a reward for distinguished or good service. Only a certain number of annuities is granted. This reward is held either for life or until an officer succeeds to his Colonel's Allowance.

GOODWIN COEHORN.—A small Coehorn mortar fixed on a stake driven into the ground at a suitable angle, and fired by a trigger and a lanyard. It is a surprisingly effective little piece, throwing a 3-inch shell to a very great distance, and may be carried one under each arm.

GORDIAN KNOT.—The traditional origin of this famous knot was as follows: Gordius, a Phrygian peasant, was once plowing in his fields, when an eagle settled on his yoke of oxen, and remained till the labor of the day was over. Surprised at so wonderful a phenomenon, he sought an explanation of it, and was informed by a Prophetess of Telmissus that he should offer sacrifice to Zeus. He did so, and out of gratitude for the kindness shown him married the Prophetess, by whom he had a son, the famous Midas. When Midas grew up, disturbances broke out in Phrygia, and the people sent messengers to the oracle at Delphi, to ask about choosing a new King. The messengers were informed that a King would come to them riding on a car, and that he would restore peace. Returning to Phrygia, they announced these things, and, while the people were talking about them, Gordius, with his father, very opportunely arrived in the requisite manner. He was immediately elected King, whereupon he dedicated his car and yoke to Zeus, in the acropolis of Gordium (a city named after himself), the knot of the yoke being tied in so skillful a manner that an oracle declared whoever should unloose it would be Ruler of all Asia. When Alexander the Great came to Gordium, he cut the knot in two with his sword, and applied the prophecy to himself.

GORE.—In Heraldry, a charge consisting of one third of the shield cut off by two arched lines, one drawn from the dexter or sinister chief, and the other from the bottom of the escutcheon, meeting in the fess point. A gore sinister is enumerated by Heralds as one of the abatements or marks of dishonor borne for unknightly conduct. See *Gusset* and *Heraldry*.

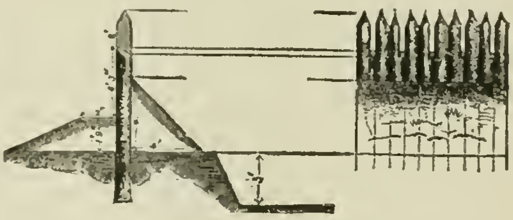


Gore.

GORGE. — 1. A cavetto, hollow member, or round concave molding, containing the quadrant of a circle, and used as an ornament in cornices. The term is commonly applied to the entrance into any piece of a fortification, which consists of the distance or space between the inner extremities of the two faces. See *Gorge of Mountains.*

2. In fortification, the opening on that side of the work corresponding to the body of the place, or the side whence comes the defense. In isolated works, the gorge is sometimes intrenched. The gorges of works not attached to a fortress, but which are its dependencies, are in general open, or without parapets, in order that the enemy may not cover himself from the fire of the place if he should seize such detached works. If the works are liable to surprise, and their gorges cannot be shut, a row of palisades are planted there, and mines are prepared so as to overthrow the enemy if he should seize the work and attempt to construct a lodgment there. The gorge of a bastion is usually an open space between the extremities of the flanks of the bastion. The larger this gorge is, the better is the defense; for when the ruined bastion is about to fall by siege into the hands of the enemy, the defenders can construct defensive works or dig small ditches in the gorge of the abandoned bastion. Such resistance sometimes drives the besiegers to the necessity of battering in breach the curtain.

A stockade is the best inclosure for the gorge of a work. The outline or plan of the gorge should be



Section and Elevation of Stockade of Gorge.

a small bastion front, or a tenaille, for the purpose of obtaining a flank defense. The trunks for the stockade should be ten or twelve inches in diameter and eleven feet in length. It will be best to square them on two sides, so that they may have about four inches of surface in contact. The top of the stockade should be at least eight feet above the ground. To arrange it for a defense, a banquette is thrown up against it on the interior; the height of the banquette one foot nine inches. A strip about two feet in length should be cut from the top of two adjacent trunks with a saw, so that when they are placed side by side there shall be an opening at top, between them, eight inches wide on the interior and two and a half inches on the exterior; this opening, through which the muzzle of the musket is run out in firing, is termed a *loop-hole.* The distance between the loop holes should be three feet. In this arrangement the bottom of the loop-holes will be six feet above the ground on the exterior, to prevent the enemy from closing on them to stop them up or use them in the attack. About four feet in front of the stockade a ditch is made, twelve feet wide and three feet deep. The earth from the ditch is thrown up against the stockade, in a slope, to the level of the bottom of the loop-hole, to prevent the enemy from attempting to cut down the stockade.

GORGED.—When a lion or other animal has a crown by way of collar round its neck, it is said heraldically to be gorged.

GORGE OF MOUNTAINS.—The passage, more or less compressed, between two mountains, which is used as a passage-way into valleys. Gorges are important military points. If they lead to an intrenched camp, it is necessary to fortify them, and there post grand guards; these positions are the principal theaters for affairs of posts.

GORGERIN.—A portion of armor at the bottom of the helm and below the *barière*. It was used instead of the mail camail to protect the neck. See *Gorget*.

GORGET.—That part of the ancient armor which defended the neck. Also a crescent-shaped ornament formerly worn by military officers on the breast. The gorget ceased to be worn, like other articles of body-armor, during the reign of Queen Anne.

GORGONS.—In military antiquity, a warlike female nation of Libya, in Africa, that had frequent quarrels with another nation of the same sex, called *Amazons*.

GOTHS.—The name of a powerful nation of antiquity, belonging to the Germanic race. By some writers they are thought to have had a Scandinavian origin, which was the belief of their own historian, Jornandes. Indeed, Jornandes, Procopius Capitolinus, and Trebellius Pollio identified them with the Getæ, a branch of the Thracian group of nations; but later researches, especially those of Dr. Latham, leave it almost without a doubt that the Goths were originally Germans. The earliest notice of them extant among the writers of antiquity is that of Pytheas of Marseille, who lived about the time of Alexander the Great, and wrote a book of travels, some fragments of which have been preserved in the works of other writers. In one of these fragments we find mention made of a tribe of *Guttones* bordering upon the Germans, and who lived round a gulf of the sea called Mentonomon, a day's sail from the Island of Abalus, where they used to gather amber and sell it to the neighboring Teutones. This gulf, there is every reason to believe, was the *Frisches Haff*, situated on the Prussian shore of the Baltic. The next notice that occurs of the Goths is in the *Germania* of Tacitus, in which they are called *Gothones*, and are represented as dwelling beyond the Lygii; in the same direction, that is, as the one pointed out by Pytheas, though not on the sea-coast. Tacitus also distinguishes them from the Gothini, a tribe east of the Quadi and Marcomanni, and who are represented by him as using the Gallican tongue. The Gothones, according to this historian, were under regal government, and on that account not quite so free as the other tribes of Germany, but still they enjoyed a considerable amount of liberty. The tribes next beyond them, and dwelling immediately on the sea-coast, were the Rugii and Lemovii, whose form of government was also monarchical, and their weapons, like those of the Gothones, round shields and short swords.

GOUDRONS.—Small fascines, or fagots, which are well steeped in wax, pitch, and glue, and then are lighted for the pupose of setting fire to beams, planks, traverses, galleries, pontons, etc. They are likewise used in various shapes and ways to convey light into the ditches or upon the ramparts.

GOUR.—An article of forage fed to elephants in India. It consists of wheaten cakes mixed with molasses, and the daily ration is from 15 to 30 pounds, according to the size of the animal.

GOURDIN.—A flat stick, two or three fingers in breadth, which was used by the French to punish galley-slaves.

GOVERNMENT.—The Constitution of the United States provides that Congress shall make rules for the government and regulation of armies. By government is understood not only the body of fundamental laws of a State, but also the body of persons charged with the management of the executive power of a country, direction, power or authority which rules a community, administration, rule, management. Government of the military is that branch of the code which embraces the creation and regulation of the military *hierarchy*, or the gradual distribution of inferior authority. The power of making rules of government is that of Supreme Command, and from this living principle proceeds the localization of troops; their organization and distribution; rules for rewards and punishments; and generally all rules of government and *regulation* whatsoever which the legislature may judge necessary to maintain an efficient and well-disciplined army. All authority over the land forces of the United States must therefore be derived from Congress. For although the President is the Commander-in-Chief, yet his functions as such must be regulated by Congress, under the 17th clause of Section 8 of the Constitution, as well as under the general authority of Congress to make rules for the government and regulation of the land forces. The President cannot be divested of power which Congress may assign to any inferior Military Commander, because the authority of the greater includes that of the less. But all authority over the land and naval forces save the *appointment* of the Commander-in-Chief rests with Congress, and no authority can be exercised not delegated by Congress, except such as may be fairly deduced from powers given for the effective discharge of the duties annexed to his office.

GOVERNOR.—1. The officer placed by royal commission in the military command of any fortress, not only over the garrison but over the inhabitants. In time of war it is an office of great responsibility, and at all times requires considerable experience and military information. In the United States a Governor is invested with supreme authority in a State.

2. A device which regulates the admission of steam to the engine according to the rate of motion. The intention is to maintain uniform velocity, and any acceleration of speed above a given rate causes a valve to be partially closed, diminishing the area of steam-passage: contrariwise in case of flagging in the speed of motion of the engine. Fig. 1 shows a vertical section through the center of the governor and its parts, together with a cross-section of the girder of the Cummer engine; this section being along the center line of the governor-shaft shows the main eccentric, cast solid with it. The cut-off eccentric, with its sleeve, it will be observed, fits loosely on the governor-shaft, and is connected with the flying ends of the governor-weights by means of rods or links (as shown in Fig. 2) in such a manner that the cut-off eccentric, with its sleeve, is moved around the governor-shaft, either forward or backward, as the flying weights change their position; by this means the steam is cut off correspondingly earlier or later in the stroke as the governor or flying weights adjust themselves to the load.

The governor-shaft is driven from the main shaft by a train of gears, one of which appears in section in Fig. 1. The governor-case, to which is attached the flying weights, is keyed to the governor-shaft, and revolves with it. It will be noticed the governor-shaft is hollow, and has passing through it a thrust-rod. One end of this thrust-rod is attached to a cross-bar, which, passing through a slot in the governor-shaft, is thereby made to revolve with it. The cross-bar just referred to is connected with the governor or flying weights by suitable connections and bell-cranks shown in Fig. 1. The other end of the thrust-rod fits into a step which is jointed to the vertical arm of the large bell-crank shown in Fig. 1. It will be clear that any movement of the weights in the governor case would cause the thrust-rod to move correspondingly out or in, and thus operate or change the relative position of the large bell-crank and cause the weight located under the engine and attached to the end of the horizontal arm of the bell-crank to be raised or lowered in an amount corresponding to the outer or inner position of the governor-weights.

Referring once more to the cut-off eccentric, Fig. 2 shows how the flying ends of the governor-weights are connected by means of two rods and a clamp collar with the sleeve of the cut-off eccentric, so that, as the governor-weights change their position, the eccentric, with its sleeve, moves around the shaft either forward or backward. When the cut-off eccentric is rotated forward, the steam is cut off earlier in the stroke; when the eccentric is rotated backward, the steam is cut off later in the stroke. The extreme range of cut-off as controlled by this governor may be from 0 to 8–10 of the stroke measured from the beginning; these extremes correspond to the extreme positions of the flying weights, or, in other words, the engine is controlled by the governor from a simple friction-load to the full capacity of the engine. It will be seen that the dead weights suspended from the horizontal arm of the large bell-crank can be varied or adjusted in amount. This provision is made in order to regulate the speed of the engine. Whenever a change, either faster or slower than standard speed, is desired, the required variation is effected by simply adding to or taking from these loose weights under the bed; the change is easily made without the necessity for stopping the engine.

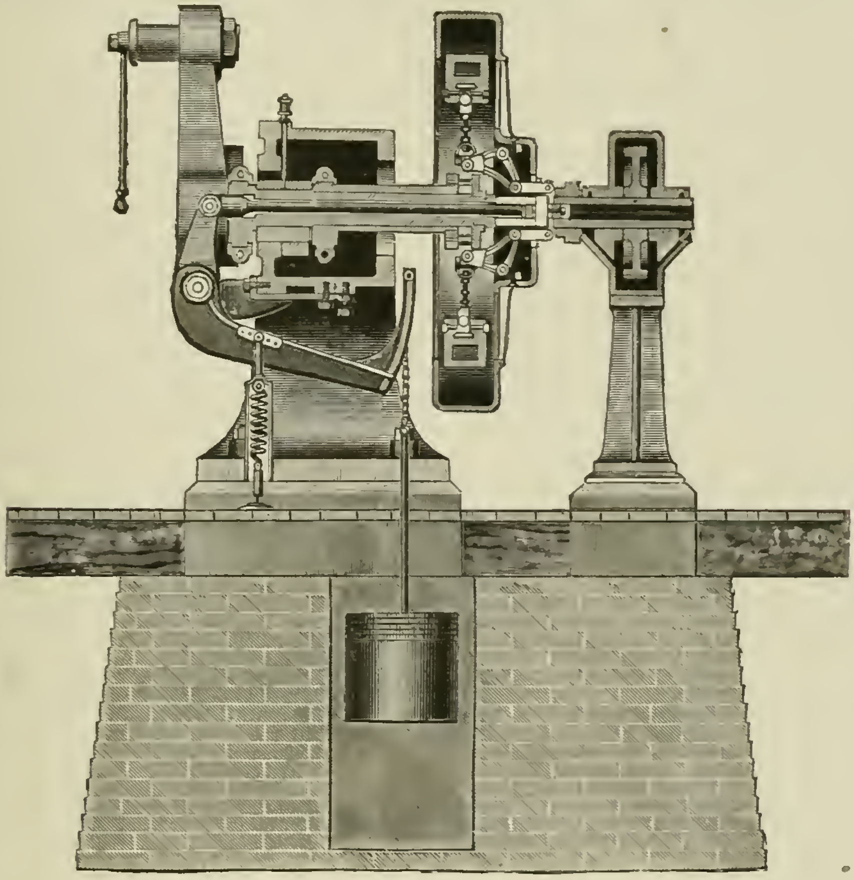


Fig. 1.

The object of the governor is to preserve a certain determined speed with the smallest possible variation from constant speed as changes in the load occur. The cut-off must always be proportioned to the load. When no load is on, steam is cut off very early in the stroke, and the flying weights are at their extreme outer position; with a heavy load steam follows further, and the weights are nearer their inner position. Between these two limits any number of positions of the weights and corresponding angular positions of the cut-off eccentric may be had, and in each position as the steam is adapted to the load, the slightest increase or decrease in speed must make a change in the cut-off and bring the engine again to standard speed. In order that the governor may be very sensitive and instantly feel any variation of speed, it is necessary that the centrifugal force of the flying weights and the opposing centripetal force exerted by the dead weights and spring on the large bell-crank be exactly balanced in every position they can possibly take; then any change of speed will cause the flying weights to instantly move in or out and be just as well balanced in their new position and as sensitive to any other variation in speed as they were before. This balancing of the centrifugal force, which is generated by the flying weights of the governor, is accomplished by the weights suspended from the horizontal arm of the large bell-crank and the spring attached to the same arm. The governor is adjusted for whatever speed may be desired.

The mechanism of the governor is such as to permit of a delicate adjustment. Referring to Fig. 1, it will be seen that the point of attachment of the spring

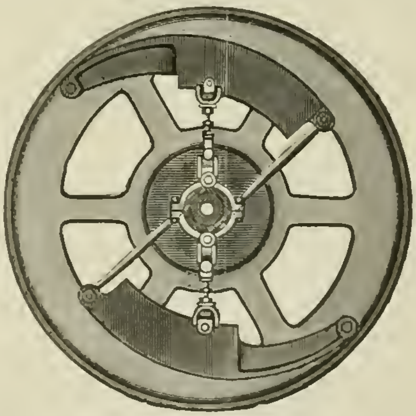

Fig. 2.

may be shifted so as to get more or less leverage and extension of the spring, and therefore more or less centripetal force. There is a series of holes on the arm for this purpose. The governor-weights and the tension of the spring are all calculated as closely as may be; then the final adjustment is made by attaching the spring at a greater or less distance from the fulcrum of the bell-crank, and thus the balance between the opposing forces may be exactly determined, and the adjustment so accurately made that these forces increase and decrease in the same ratio.

There is a point to be noted in connection with this spring; the dead weights furnish a constant centripetal force to balance the centrifugal force of the weights when at their inner position. All the spring has to do is to furnish what is necessary to balance the increase of centrifugal force as the weights move out from the center; the initial tension is 0; its duty is light, it is never severely strained, and it has periods of rest, so that its elasticity does not become impaired. In this respect this governor differs from all those in which a spring is required to furnish all the necessary centripetal force. It is quite obvious that such a spring has a more severe and very injurious duty to perform, because it is always under tension, so that its elasticity soon becomes impaired and the Governor does not act properly. A comparison of the two methods of construction will show clearly the superiority of this governor and explains the very close governing under varying loads for which the Cummer engine has achieved an excellent reputation.

The effectiveness and force of a governor-weight varies in the ratio of the squares of the velocities; and as the velocity depends upon the radius of gyration, it is easily seen why the weights should approach and recede from the center by only a small amount, and this is permitted by the small movement required to operate the eccentric; and it follows also that, when the weights are at their inner position, and the engine is following $\frac{3}{8}$ to $\frac{3}{4}$ of the stroke, the weights have moved inward so little, or from $\frac{1}{8}$ to $\frac{1}{4}$ of what would be necesary if the governor was placed on the main shaft, that the governor has the valves and the engine as much under control as when in any other position. It is important that the governor-weights be given such an adjusting movement that, when at their inner position, their force and value for governing shall not be impaired. From what has been said, it will be seen that the weights are always in an effective position and the governor acts equally well from 0 up to $\frac{3}{4}$ of the stroke. See *Steam engine*.

GOVERNOR-GENERAL OF INDIA.—The Chief Executive Officer of that Dependency, who has also the rank and position of a Viceroy. He is appointed by the Crown for a period of five years, which, however, can be extended. The Governor-General is subject in all matters of moment to the control of the Crown, through the Secretary of State for India. He is assisted by an Executive Council, composed of six members, should he see the necessity of so many, viz., two civilians, a law and financial member, a military member, and a member of public works. All acts of the Government are performed in the name of the Governor-General "in Council;" not that he is necessarily bound to the majority of his Council, as he can dissent altogether from their opinion, and act accordingly, if he thinks fit. The above members, with the addition of a civilian from Madras and Bombay, a few non-official members selected from the European commercial community, and one or two native noblemen, constitute the Supreme Legislative Council for making laws and regulations. But the Governor-General has the power of making rules and regulations, on an emergency, with reduced numbers of his Council.

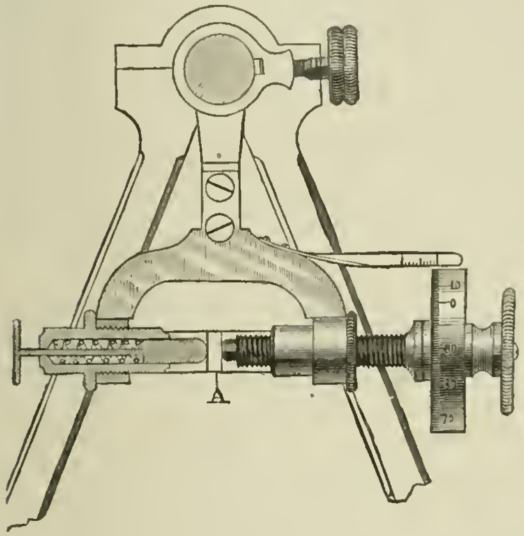
GOWRIE CONSPIRACY.—One of the most singular events in the history of Scotland, which took place in August, 1600. On the 5th of that month, as King James VI., then residing at Falkland Palace, in Fife, was going out to hunt, Alexander Ruthven, brother of the Earl of Gowrie, whose father had been executed for treason in 1584, came to his Majesty, and informed him that, on the previous evening, he had seized a person of a suspicious appearance, and evidently disguised, with a pot full of foreign gold hid under his cloak, and had confined him in his brother's house at Perth. Conceiving him to be an agent of the Pope or the King of Spain, the King agreed to examine the man himself, and without waiting to change his horse, set out for Perth, attended only by the Duke of Lennox, the Earl of Mar, and about twenty others. Soon after his arrival, while his retinue were at dinner, Ruthven conducted the King up a winding staircase and through several apartments, the doors of which he locked behind him, and brought him at last to a small study, where stood a man in armor, with a sword and dagger by his side. Snatching the dagger from the man's girdle, Ruthven held it to the King's breast, and said, "Who murdered my father? Is not thy conscience burdened by his innocent blood? Thou art now my prisoner, and must be content to follow our will, and to be used as we list. Seek not to escape; utter but a cry, make but a motion to open the window, and this dagger is in thy heart." The King expostulated with Ruthven, who so far relented that he went to consult his brother, leaving the King in charge of the man in armor. In the mean time, one of Gowrie's servants hastily entered the apartment where the King's retinue were, and announced that the King had just ridden off towards Falkland. All hurried into the street, and the Earl, with the utmost eagerness, called for their horses. On Alexander Ruthven's return to the King, he declared that there was now no remedy, but that he must die, and proceeded to bind his hands with a garter. The King grappled with him, and a fierce struggle ensued. Dragging Ruthven towards a window looking into the street, which the man in armor had opened, the King cried aloud for help. His attendants knew his voice, and hastened to his assistance. Lennox and Mar, with the greater number of the royal train, ran up the principal staircase, but found all the doors shut. Sir John Ramsay, of the Dalhousie family, one of the royal pages, ascending by a back stair, entered the study, the door of which was open, and seizing Ruthven, stabbed him twice with his dagger, and thrust him down the stair, where he was killed by Sir Thomas Erskine and Sir Hugh Herries. Upon the death of his brother, Gowrie rushed into the room, with a drawn sword in each hand, followed by seven retainers, well armed, and was instantly attacked. Pierced through the heart by Sir John Ramsay, he fell dead without uttering a word. The inhabitants of Perth, by whom Gowrie, who was their Provost, was much beloved, hearing of his fate, ran to arms, and, surrounding the house, threatened revenge. The King addressed them from a window, and admitted the Magistrates, to whom he fully related all the circumstances, on which they dispersed, and he returned to Falkland. Three of the Earl's servants were executed at Perth. The man in armor, Andrew Henderson, the Earl's steward, was pardoned. All who were examined were totally ignorant of the motives which prompted the brothers Ruthven to such a deed, and they still remain in some degree of mystery, although recent discoveries have led to a pretty general belief that the object of the conspirators was to possess themselves of the King's person, to convey him by water to Fast Castle, and either to give him up to England, or to administer the Government in his name in the interest of that country and of the Presbyterian leaders at home. Most of the documents relating to the plot are printed.

GRADE.—A term synonymous with rank, and peculiarly applicable to the different ranks among officers, beginning from an Ensign to the Commander-in-Chief of an army. See *Rank*.

GRADIENT.—In Heraldry, a tortoise when walking is said to be gradient. The term is used chiefly in connection with earthworks and roads to signify a departure of the line from a perfect level.

GRADIENTER.—An attachment often used with transits for fixing grades, determining distances, etc.

It is shown in the drawing, and consists mainly of a screw attached to the semicircular expanded arm of the ordinary clamp of the telescope axis; the screw is accurately cut to a given number of threads, and passing through a nut in one side of the arm, presses against a little stud, A, fixed to the inside surface of the right-hand standard. In the other side of the semicircular arm is inserted a hollow cylinder containing a pin actuated by a strong spiral spring, the end of the pin pressing against the side of the stud opposite that in contact with the screw. Near the other end of the screw, and turning with it, is a wheel, or micrometer, the rim of which is plated with silver, and divided into one hundred equal parts. A small silver scale, attached to the arm and just above the micrometer-wheel, is divided into spaces, each of which is just equal to one revolution of the screw; so that by comparing the edge of the wheel with the divisions of the scale, the number of complete revolutions of the screw can be easily counted. It will be seen that when the clamp is made fast to the axis by



Gradienter.

the clamp-screw, and the gradienter screw turned, it will move the telescope vertically, precisely like the tangent-screw ordinarily used. And as the value of a thread is such that a complete revolution of the screw will move the horizontal cross-wire of the telescope over a space of one foot on a rod at a distance of one hundred feet, it is clear that when the screw is turned through fifty spaces on the graduated head, the wire will pass over fifty one hundredths, or one half a foot on the rod, and so on in the same proportion. In this way the gradienter can be used in the measurement of distances, precisely like the micrometer already described in the article on the Engineer's Transit. Grades can also be established with great facility, as follows: First level the instrument; bring the telescope level to its center by the clamp and gradienter-screw; move the graduated head until its zero is brought to the edge of the scale; and then turn off as many spaces on the head as there are hundredths of feet to the hundred in the grade that is to be established. See *Micrometer*.

GRADIVUS.—The Roman Mars, who as a war-god was surnamed *Gradivus* (= *grandis divus*, the great god), also bore the surname of *Silvanus*, and appears to have been originally an agricultural deity; and propitiatory offerings were presented to him as the guardian of fields and flocks; but as the fierce shepherds who founded the city of Rome were even more addicted to martial than to pastoral pursuits, one can easily understand how *M. Silvanus* should have, in the course of time, become the "God of War." See *Mars*.

GRADUATION.—The art of dividing mathematical, astronomical, and other instruments. The simplest problem in graduation is the dividing of the straight line, such as an ordinary scale or rule. This is commonly done by copying from a standard scale, for which purpose a dividing square and a suitable knife for cutting the divisions are used. The dividing square is a hard steel straight-edge, with a shoulder at right angles like a carpenter's square. This is made to slide along the standard scale, and halt at each required division, when a corresponding one is cut upon the rule, etc., by using the steel straight-edge as a guide to the knife. The *original graduation* of a straight line into equal divisions, as in making a first standard scale, etc., is performed either on the principle of *bisection* or *stepping*. In bisecting, the points of a beam-compass are adjusted to nearly half the length of the line to be divided; one point is then placed at one end of the line, and a faint arc struck towards the middle: this is repeated at the other end; the small distance between these arcs is then carefully bisected with the aid of a fine pointer and magnifier, which gives an accurate half of the line. The half thus obtained is again bisected in like manner, and these quarters bisected again, and so on until the required subdivision is attained. Stepping is performed with delicately pointed spring-dividers, which are set at once as nearly as possible to the opening of the small division required; then the points are made to step on, leaving at each step a very fine dot; and when it is found that the last dot either falls short of or overpasses the end of the line, the opening is adjusted accordingly, until perfect accuracy is obtained. Thus, if a line were divided into a thousand parts, and each division were $\frac{1}{1000}$ too long or too short, the error would amount to a whole division at the end of a thousand steps. The method of bisection is practically the most accurate, and has been adopted by Graham, Bird, Ramsden, Troughton, and all other eminent artists in original graduation. Curved lines are divided on this principle. The chord of an arc of 60° is equal to the radius; therefore the opening of the compasses required for striking the circle gives this arc at once to start with. An arc of 90°, or a quadrant, is obtained by bisecting 60° and adding the half. By continual bisection of 60°, the finer graduations are produced. The amount of care, patience, skill, and delicacy of touch required in the original graduation of important astronomical instruments is such that not above one or two men in a generation have been found competent to the task, and these have become almost as famous as the astronomers who have successfully used the instruments. It would be out of place here to point out in detail the minute precautions and methods of correction that are adopted in this most delicate manipulation; but, as one example, we may mention the fact that Graham, when dividing the mural quadrant for the Greenwich observatory, measured his larger chords from a scale made for the purpose; but before laying these down on the quadrant, he left the scale, beam-compasses, and quadrant to stand for a whole night, in order to acquire exactly the same temperature, and that neglect of this precaution would have involved a notable amount of error. The necessity of such extreme accuracy will be understood when we consider the application that is made of these divisions. When, for example, the mariner determines his latitude by taking the meridian altitude of the sun, the graduated arc of the limb of the sextant or quadrant he uses represents, practically, the curved surface of the globe, and the error is magnified just to the same extent as the radius of the earth exceeds that of the divided arc of the instrument. Supposing this arc to be part of a circle of 60 inches circumference, each degree will occupy $\frac{1}{6}$ of an inch. An error of $\frac{1}{100}$ of an inch in the division would thus mislead the mariner to an extent of more than four statute miles as regards his position on the waters. But such a ship's quadrant is but a coarse and rude instrument compared with astronomical instruments for measuring celestial angular distances by means of a divided arc; in these an error of a thousandth part of an inch would be regarded as one of very serious magnitude. See *Dividing-engine*.

GRADUATION OF REAR SIGHTS.—The rear sights of small-arms are graduated with elevation-marks for certain distances, generally every hundred yards; in aiming with these, as with all other arms, it is first necessary to know the distance of the object. This being known, and the slider being placed opposite the mark corresponding to this distance, the bottom of the rear-sight notch and the top of the front sight are brought into a line joining the object and the eye of the marksman. The term *coarse sight* is used when a considerable portion of the front sight is seen above the bottom of the rear-sight notch; and the term *fine sight*, when but a small portion of it is seen. The graduation-marks being determined for a fine sight, the effect of a coarse sight is to increase the true range of the projectile. If the form of the trajectory be known, the rear sight of a fire-arm can be graduated by calculation; the more accurate and reliable method, however, is by trial. Suppose it be required to mark the graduation for 100 yards; the slider is placed as near the position of the required mark as the judgment of the experimenter may indicate; and, with this elevation, the piece is carefully aimed, and fired, say, ten times at a target placed on level ground, at a distance of 100 yards. If the assumed position of the slider be correct, the center of impact of the ten shot-holes will coincide with the point aimed at; if it be incorrect, or the center of impact be found below the point aimed at, then the position of the slider is too low on the scale. Let P be the point aimed at, and P' the center of impact of

the cluster of shot-holes; we have, from close similarity of the triangles, $A'F : FP :: AA'' : PP'$, from which we can determine $A'A''$, the quantity that must be added to AA' to give the correct position of the graduation-mark for 100 yards. If the center of impact had been above P, the trial-mark would have been too high. Lay off the distance AA'' above A'', on the scale, and we obtain an approximate graduation for 200 yards, which should be corrected in the same way as the preceding, and so on. The distance PP' is found by taking the algebraic sum of the distances of all the shots from the point P, and dividing it by the number of shots. It will be readily seen that an approximate form of the trajectory may be obtained by drawing a series of lines through the different graduation-marks of the rear sight, and the top of the front sight, and laying off from the front sight, on each line, the corresponding range. The points thus determined are situated in the required trajectory. See *Sight*.

GRAINOIR.—A term used in the French artillery to signify a sort of sieve, in which there are small round holes for moist powder to be passed through, in order to make the grains perfectly round.

GRAINS D'ORGE.—A coat of mail in riveted rings. It is entirely formed of metal rings, and has neither wrong side nor lining.

GRAND DIVISION.—A battalion or regiment being told off by two companies to each division is said to be told off in grand divisions; hence grand-division firing is when the battalion fires by two companies at the same time, and is commanded by one officer only.

GRAND GUARD-MOUNTING.—The grand guard-mounting is conducted upon the same principle as the regimental guard-mounting. Each regimental detachment is assembled on its parade and verified by the Adjutant, after which it is marched to the general parade by the senior officer or non-commissioned officer of the detachment. The officer of each detachment, having formed it in open order, places himself two yards in front of its center, the guides taking their places in the line of file-closers as the detachment is halted. A Staff-officer counts the files, verifies the details by reference to written orders, causes the guard to count fours, divides it into two or more platoons, and then dresses it to the right. A space for the guide is left between the platoons, which is temporarily occupied by a file closer, and through which the file-closers pass at the command: 1. *Officers and non commissioned officers to the front and center*, 2. MARCH. Each platoon is inspected by its Chief. The guard having passed in review before the Field Officer of the Day is formed to the left into line, and halted by the Staff-officer. The Field Officer of the Day then sends the guard by detachments to the various posts. See *Guard-mounting*.

GRAND GUARDS.—The main guards covering an army or camp from an attack by the enemy. Inasmuch as the grand guards furnish the outposts, and serve as their supports, not more than one third of their force should be taken for the outposts. The grand guards are posted on the principal avenues leading to the detachments on which they are to fall back, if driven in; and, when of infantry, about 200 paces, and of cavalry, 600 to 800 paces, in the rear of the outposts. The points which they occupy should be selected both to secure them from the enemy's view and to give a ready communication between them and their respective outposts. No difficult or broken ground should lie between the grand guards and their outposts; if any such occur, particularly if it be of a nature to offer facilities to an enemy to penetrate to the rear, the whole should be posted on the farther or hither side; and in preference in the latter position, if by it the chain of posts can be kept unbroken. Grand guards are chiefly to watch the enemy in front; their flanks are protected by each other, and the camp must furnish posts to protect their rear and secure retreat. In broken or mountainous countries, particularly if the inhabitants are ill-disposed, intermediate posts must be established when it is necessary to post the grand guards at a distance from the camp. The General of Division, if he thinks proper, changes the stations and orders of these guards, and establishes posts to connect the brigades or protect the exterior flanks.

The following are the standing instructions to grand guards, beside the special orders given in each case: To inform the nearest posts and the Field Officer of the Day, or the General of Brigade, of the movements of the enemy, and of the attacks they receive or apprehend; to examine every person passing near the post, particularly those coming from without; to arrest suspicious persons, and all soldiers and camp-followers who try to pass out without permission, and to send to the General, unless otherwise directed, all country people who come in. Deserters are disarmed at the advanced-posts, and sent to the Commander of the grand guard, who gets from them all the information he can. If many come at night, they are received *cautiously, a few at a time.* They are sent in the morning to the Field Officer of the Day, or to the nearest post or camp, to be conducted to the General of the Brigade. All suspected persons are searched by the Commanders of the posts. Grand guards are often charged with the care and working of telegraphic signals. The Commandants of grand guards visit the sentinels often; change their positions when necessary; make them repeat their orders; teach them under what circumstances and at what signals to retire, and particularly not to fall back directly on their guard if pursued, but to lead the enemy in a circuit. The fires of grand guards should be hidden by some sort of screen. To deceive the enemy, fires are sometimes made on ground not occupied. Fires are not permitted at small posts liable to surprise.

GRAND-MASTER.—The title of the Head of the Military Orders, the Hospitallers, the Templars, and the Teutonic Knights; see these articles. The title originally borne by the Superior of the Hospitallers was simply "Master" (*Magister*); but in 1268 Hugh de Reval took that by which they are since known—Grand-Master, *Magnus-Magister*. In the Teutonic Order, the title "Master," with different modifications, was applied to the several Superiors of the Order in the various countries. Thus, the Superior of Germany was styled *Teutsch-Meister*, "German Master." The Superior of Livonia was called *Heer-Meister*, "Military Master." In all these Orders the office of Grand-Master was held for life. The name was also used in the Dominican Order.

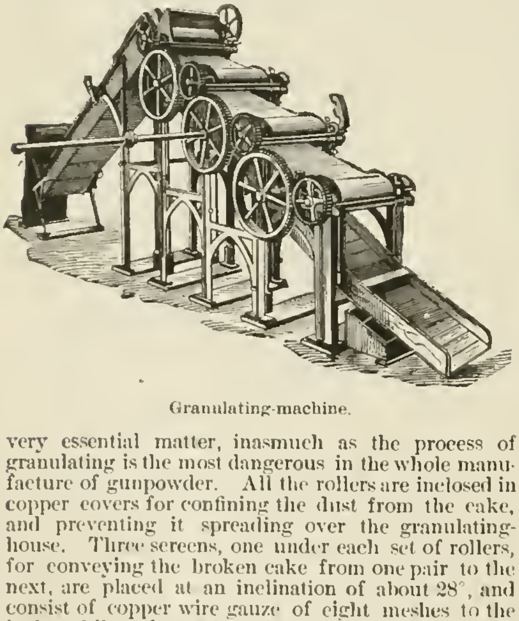
GRAND-MASTER OF CROSS-BOWS.—The *personnel* of the French artillery was for a long time prior to 1420 retained, together with the engineers, under the general direction of an officer who was titled *Grand-Master of Cross-bows*. In 1420 the Master-General of Artillery was made independent of this officer.

GRAND ROUNDS.—Every General Officer, or the Commander of a Post or Garrison, may visit the guards of his command, and go the Grand Rounds, and be received in the same manner as prescribed for the Officer of the Day. The Officer of the Day, wishing to make the Rounds, takes an escort of one non-commissioned officer and two men. Whenever the Rounds are challenged by a sentinel, the Sergeant answers, "Grand Rounds!" and the sentinel replies, "Halt, Grand Rounds! Advance, Sergeant, with the countersign!" Upon which the Sergeant advances and gives the countersign. The sentinel then cries, "Advance, Rounds!" and stands at a carry till they have passed. When the sentinel before the guard challenges, and is answered, "Grand Rounds!" he replies, "Halt, Grand Rounds! Turn out the guard; Grand Rounds!" Upon which the guard is drawn up with arms at a carry. The Officer Commanding the Guard then orders a Sergeant and two men to advance; when within ten paces, the Sergeant challenges. The Sergeant of the Grand Rounds answers, "Grand Rounds!" The Sergeant of the Guard replies, "Advance, Sergeant with the countersign!" The Sergeant of the Rounds advances alone, gives the countersign, and returns to his Round. The Sergeant of the Guard calls to his officer, "The countersign is right!" on which the Officer of the Guard calls, "Advance, Rounds!" The guard being at a carry, the Officer of the Rounds advances alone to the Officer of the Guard, who keeps his post and gives to him the parole. He then examines the guard, orders back his escort, and, taking another one, proceeds in the same manner to other guards. All material instructions given to a sentinel on post by persons entitled to make Grand Rounds are promptly and fully reported to the Commander of the Guard. See *Rounds*.

GRAND SERJEANTY.—The most honorable of all the ancient feudal tenures. According to Lyttleton, tenure by Grand Serjeanty is where a man holds his lands or tenements of the Sovereign Lord the King by such services as he ought to do in his proper person to the King, as to carry his banner or his lance, or to lead his army, or to be his Marshal, or to carry his sword before him at his coronation, or his Carver, or his Butler, or to be one of his Chamberlains of the receipt of his Exchequer, or to do other like services. This tenure must have been held of the King. Where lands were held of a subject, on condition of performance of services identical with those which were rendered to the King, the tenure was not Grand Serjeanty, but Knight's Service. Thus, lands on the Scottish border held of the King by cornage—i.e., on condition of winding a horn to give notice when the Scots had crossed the border—were held in Grand Serjeanty; but lands held of a subject for the same service were held in Knight's Service. Tenants holding by Grand Serjeanty were free from escuage, which usually appertained to Knight's Service, and in general could only be called upon to perform their services *infra quatuor maria*, within the Kingdom. The services in Grand Serjeanty were to be performed by the tenant in person, where he was able to do so. The office of attendance on the Sovereign's person was esteemed so honorable that no one below the dignity of a Knight could perform it. Hence, where lands held by Grand Serjeanty were in the possession of a citizen, he was permitted to perform his service by Deputy. This tenure by Grand Serjeanty was, in common with other military tenures, reduced to common Socage, except so far as regards the honorary services, which continue to be observed to this day. Thus, the Duke of Wellington holds of the Crown his estate of Strathfieldsaye on condition of presenting to the Sovereign a flag bearing the national colors on each succeeding anniversary of the Battle of Waterloo. The manor of Woodstock, with the demesne, in which is situated Blenheim Park, is held by the Duke of Marlborough by Grand Serjeanty, on condition of presenting to the Queen and her heirs, at the Castle of Windsor, a standard of France on the 13th of August yearly, being the anniversary of the day on which the Battle of Hochstädt was fought, near the village of Blenheim, on the banks of the Danube. The tenure of Grand Serjeanty was observed throughout the Continent of Europe. "The free-born Franks," says Mr. Hallam, *Middle Ages*, "saw nothing menial in the titles of Cupbearer, Steward, Marshal, or Master of the Horse, which are still borne by the noblest families in every country in Europe, and by Sovereign Princes in the Empire. The Count of Anjou, under Louis VI., claimed the office of Great Seneschal of France—i.e., to carry dishes to the King's table on state-days. Thus the feudal notions of Grand Serjeanty prepared the way for the restoration of royal supremacy, as the military tenures had impaired it." In Scotland, Grand Serjeanty was not known as a separate tenure—that is to say, lands held on condition of honorary services rendered to the Sovereign were not attended with any privileges other than those attaching to lands held in a similar manner of a subject superior. In that country a tenure by honorary service was known as a Blanch Holding.

GRAND TACTICS.—Tactics, or that branch of the art of war which treats of the methods of drawing up and moving troops systematically, has two modifications. 1. *Minor* or drill tactics, which embraces that setting up and preliminary drilling of soldiers essential to discipline, expertness in handling their weapons, and facility of movement preparatory to their employment on the field of battle. 2. *Grand* tactics, or the art of combining, disposing, and handling the troops on the field of battle. It is this latter branch of tactics that supplements strategy. In case the principles of both branches cannot be carried out at the same time, it is recommended to adhere to the rules of *Strategy* at the expense of *Tactics*, for some means may generally be found to modify bad tactical dispositions; as a change in the formation of the troops, the use of intrenchments, etc. See *Strategy* and *Tactics*.

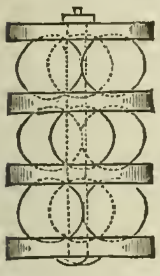
GRANULATING-MACHINE.—The machine used for granulating or reducing the pressed cake into grain-powder is somewhat similar in construction to the breaking-down machine; it is, however, fitted with four pairs of cutting rollers, and rectangular screens below the three upper pairs; these screens convey any grain not properly reduced by the one set of rollers to the next under them. The machine is composed of two side frames of gun-metal, which carry the rollers, screens, and all the other moving parts. The rollers are placed in pairs at an inclination of about 33°, and have a vertical height of 2 feet 5 inches between each pair; they are 7 inches in diameter, and make from twenty-five to thirty revolutions per minute, thus giving a speed of about 48 feet per minute to their toothed surfaces, the length of which for operating upon the powder is 2 feet 6 inches. The press-cake is fed to the machine by an endless band at the rate of about 30 lbs. per minute. The teeth in the several pairs of rollers vary in size and form. Those on the upper rollers are diamond-shaped, and resemble a series of small pyramids standing out from the surface of the rollers; these teeth are a quarter of an inch apart and the same in depth, and so arranged that those in the one roller work into the spaces of the other. The second pair of rollers have smaller teeth, but of the same form as the upper pair; they are a quarter of an inch apart, but only one eighth of an inch in depth. The teeth of the third and fourth pairs are differently shaped; in these they are formed by cutting V-shaped ribs longitudinally along the rollers and the rectangular grooves a quarter of an inch apart by one eighth of an inch in depth round their circumferences. The ribs of the one roller work into the grooves of the other, and *vice versa*, and their top and bottom edges are slightly rounded. On the side bearings, and behind each roller, there is fixed a scraper, the edge of which is provided with teeth corresponding with the grooves in the rollers, so that as the latter revolve, any powder adhering to them is cleared out, and this prevents their ever becoming clogged. The back roller of each pair is provided with a sliding bearing and is pressed forward towards the front rollers by weighted levers; this arrangement admits of their opening when necessary, and permits a glut of cake or any hard material to pass them with safety. This is a



Granulating-machine.

very essential matter, inasmuch as the process of granulating is the most dangerous in the whole manufacture of gunpowder. All the rollers are inclosed in copper covers for confining the dust from the cake, and preventing it spreading over the granulating-house. Three screens, one under each set of rollers, for conveying the broken cake from one pair to the next, are placed at an inclination of about 28°, and consist of copper wire gauze of eight meshes to the inch; while underneath, and embracing all the rollers, are three tiers of light separating-screens, contained within a deep frame set at an angle of 32°. The upper screen is of copper wire gauze of eight meshes to the inch; the second is likewise of copper wire gauze, but of sixteen meshes to the inch; while the third is a very fine (nearly close) screen, and receives the dust from the upper ones and conveys it into a box placed for the purpose. The separating-screen frame is slung from the gun-metal framing of the machine by light springs made of lancewood. The screens themselves are also carried from the frame by the same means, and the whole has a longitudinal movement given to it of 182 vibrations per minute, produced by polygonal wheels on the driving-shaft, which press against circular but loose-running wheels attached to the separating-screen frame. The surfaces of these wheels are kept in contact by the weight of the screen itself. The process of granulating the press-cake may be described as follows: The cake, having been broken into pieces, is put into a wooden hopper, which holds 700 pounds; the side of this hopper next the inclined frame is open to a shoot, and the hopper itself—when the machine is at work—moves slowly up this inclined frame, the speed being regulated so as to suit that of an endless feed-band made of canvas, with strips of leather sewn across it. A rope, set in motion by one of the machine-shafts in connection with a worm and wheel, is used to raise the hopper, the cake in which, falling through the shoot on to the endless band, is carried forward to the uppermost or first pair of rollers. From these it is conducted to each successive pair by the screens, and these, having a quick vibrating motion, allow any grain that has been broken small enough to pass through them into the upper long separating-screen in the frame underneath. Such grain as is too large to go through any of the screens is called "chucks," and is collected and passed through the machine a second time. The grain which passes the upper, or eight-mesh long screen, is used for common powder; that which passes through the sixteen-mesh long screen is suitable for rifle or small-arm powder; and that which passes through into the lower screen is dust. The powder as it falls from the surface of the different screens is collected in separate boxes placed underneath the machine for its reception. When the hopper has reached the limit of its travel upwards, and all the cake has passed on to the feeding-band, which it will do in from twenty-five to thirty minutes after the machine has been set in motion, the hopper acts, by a self-acting arrangement on a clutch, which throws the rope-wheel out of gear, and thus stops the further travel of the hopper, while a counter-balance weight prevents its descent. At the same time that the clutch throws the wheel out of gear, it relieves a catch connected with a wire spring and bell; the latter, by ringing in the bomb-proof house, wherein the workmen remain while the machine is in operation, gives them notice that the hopper is empty. After allowing about five minutes for the band and machine to become quite empty, the apparatus is stopped, and the attendants, now leaving their place of safety, enter the granulating-house, and empty the grain from the several boxes into tubs for removal. No one is on any account permitted to enter the granulating house whilst the machine is working, and as a further precautionary measure the attendants or others who have occasion to enter the house at other times wear sewn hide-leather boots. After all the powder is removed, the hopper is let down to its proper place and refilled with cake, and the machine is now again ready for use; the attendants therefore leave the granulating-house and retire to the bomb-proof building, where they set the machine in motion, and remain under cover until the bell again rings, when, after allowing a few minutes to elapse, they stop the machine, both the starting and the stopping being effected in the bomb-proof house. When a fine-grain powder is required, rollers with smaller teeth are used, together with screens of 24 and 32 meshes to the inch. The dust produced by this machine, as well as from all the other machines, is collected and taken back to the incorporating-mill, where 50 pounds of it are spread out on the bed, and after being well damped it is worked under the edge runners for about one hour; it is then fit to be sent forward to the breaking-down machine, the press, and other subsequent operations. The quantity of dust produced varies considerably, according to the condition of the teeth of the granulating rollers; if they are much worn, or become foul, as they are apt to do during damp weather, the quantity of dust will be considerably increased; or if only fine-grain powder is being made, the percentage of dust will be great. As in the case of the breaking-down machine, so with the granulating-machine, no iron or steel is exposed, and indeed there is very little of either used in its construction, the shafts and bed-plate being the only parts made of those metals; the former, as well as the whole floor of the granulating-house, is covered with soft leather hide, and the shafts are all encased in copper or gun-metal. The side frames, rollers, wheels, bolts, nuts, and all other parts of the machine are made of gun-metal, copper, or wood. A machine of the size described is capable of granulating from 130 to 140 barrels of gunpowder in a day of twelve hours, supposing each barrel to contain 100 pounds. See *Gunpowder*.

GRAPE-SHOT.—The grape shot is composed of a number of small shot arranged around a spindle on an iron disk. Formerly the shot were inclosed in a canvas bag, which was drawn together between the balls, or "quilted" by a strong line; but the present method is more simple and durable. It consists of nine shot of a size appropriate to the caliber used, which are held together by two rings and a plate at each end of the stand, connected by a rod, as shown in the drawing. The diameter of balls for grape-shot varies with the caliber, being in all cases larger than those used for canister. Grape-shot are particularly valuable for use against torpedo-boats. See *Case-shot*, *Projectiles*, and *Siege and Garrison Ammunition*.



GRAPHITE.—A crystalline modification of carbon, very different in appearance and physical properties from the diamond. It is found in Cumberland, Siberia, Ceylon, Germany and France, and in North and South America. Graphite is a very good conductor of electricity; like the diamond it is unalterable by heat. It may be prepared artificially by bringing an excess of charcoal in contact with fused cast-iron; a portion of the carbon dissolves, and separates out again on cooling in large scales. It is used sometimes, amongst other purposes, in glazing gunpowder.

GRAPHOMETER.—A name sometimes, though inappropriately, given to the protractor, an instrument used in plotting surveys. It is a semicircle, marked with 180°, and, in the large instruments, with parts of degrees. Its use is to lay off angles. See *Protractor*.

GRAPNEL.—A small anchor of several flukes, used in mooring boats or pontons for military bridges. A grapnel having five prongs is also used for escalading purposes, to aid the assailants in effecting an entry into the place. When it is thus used, it is thrown over any spot where it is likely to anchor itself. A 2-inch rope, 60 feet in length, is attached to the shank.

GRASP.—The handle of a sword, also of an oar. Also, the small part of the stock of a musket.

GRAS RIFLE.—The Chassepôt rifle, modified by Major Gras, and now the arm definitively adopted by the French army. The barrel of the Chassepôt has been retained in the conversion, keeping the same caliber of .433 inch, with four grooves from right to left, with one turn in 21½ inches. But in the new barrel the depth of the grooves is slightly diminished, and the ledges rounded off. The same caliber has been retained in order that the same cartridge may be used in all arms. A metallic cartridge has been adopted, in lieu of the "self-consuming" one used for the Chassepôt; the bullet is of compressed lead, consequently the densest and most homogeneous. Its diameter at the base is .429 inch, instead of .468 inch, in order to reduce, within the smallest limits, the enormous friction the bullet undergoes in the barrel, which considerably diminishes the initial velocity. Thus the bullet of the Gras rifle, being smaller than the bore, is forced by depression, whilst in the Chassepôt it is forced longitudinally. This diminution of friction, combined with the removal of the "chambre ardente," or space behind the cartridge in the old rifle, has produced this effect, and the initial velocity, which was 1365 feet in the Chassepôt, has attained 1491 feet in the new arm. The length of the bullet is 1.092 inch, instead of .995 inch as formerly; that is, two and a half calibers. A greased wad is placed between the powder and the bullet. The bullet is covered with a strip of paper, in order to prevent *leading*; that is, deposits of lead in the grooves, which are fatal to accuracy. The barrel of this converted weapon has been modified in such a manner as to enable it to receive the new cartridge: 1st, by an alteration in its caliber; 2d, by the removal of the *tête mobile*, or movable head, in the breech mechanism, and by a modification of the cylinder, whereby the cartridge fits in closely; and, lastly, by the substitution of a striker or piston for the needle, and by the addition of a stronger spring and a cartridge-extractor. The breech action remains, as before, on the bolt principle. The conversion of the Chassepôt to the Gras rifle is computed to cost ten francs apiece.

GRASS-CUTTERS.—Natives of India attached to the artillery and cavalry branches of the service in that country, whose sole duty is to collect and bring in grass daily for the horses of their regiment. There is one to each horse or one to every two horses; the latter is called a *jorawallah*, and receives the pay of two men, but under these circumstances he has to keep a pony, and bring in grass equal to the load of two men. The grass-cutter's pay is from 8s. to 10s. a month.

GRASSIN.—A very early name for all militia composed of light troops. Now obsolete.

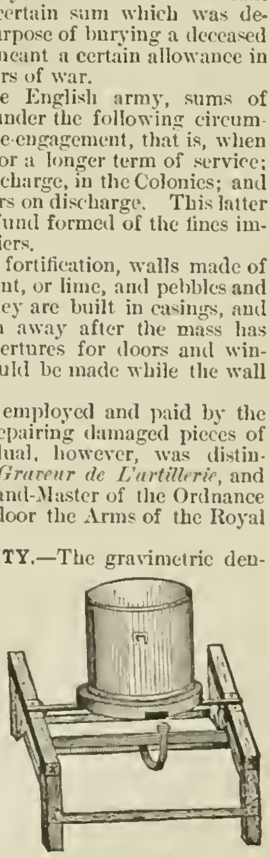
GRATIFICATION.—In a general acceptation of the term, this word meant, among the French, certain rewards which Generals gave to the troops, after a severe engagement, in testimony of their valor and good conduct. These rewards were distributed according to rank. By *gratification* was likewise meant the accumulation of a certain sum which was deposited for the specific purpose of burying a deceased soldier. The term also meant a certain allowance in money allotted to prisoners of war.

GRATUITIES.—In the English army, sums of money given to soldiers under the following circumstances: To soldiers on re-engagement, that is, when they engage to serve on for a longer term of service; to soldiers settling, on discharge, in the Colonies; and to all good-conduct soldiers on discharge. This latter gratuity is taken from a fund formed of the fines imposed upon drunken soldiers.

GRAVEL WALLS.—In fortification, walls made of a conglomeration of cement, or lime, and pebbles and small stones or slag. They are built in casings, and the planks may be taken away after the mass has properly hardened. Apertures for doors and windows, or embrasures, should be made while the wall is in process of building.

GRAVEURS.—Persons employed and paid by the founders of cannon for repairing damaged pieces of artillery. Some individual, however, was distinguished by the name of *Graveur de L'artillerie*, and was permitted by the Grand-Master of the Ordnance to exhibit over his shop-door the Arms of the Royal Artillery.

GRAVIMETRIC DENSITY.—The gravimetric density of a powder is the weight of a cubic foot of the powder expressed in ounces. It should fall between 875 and 900 ounces. This cannot be relied upon for the true density, as the shape of the grain may make the denser powder seem the lighter. It is only of value as giving a tolerably correct idea of the volume of the air-space in a given weight. The *gravimeter*, shown in the drawing, is weighed when filled loosely, and again when filled by packing the



Gravimeter.

powder. The powder, as it is poured in, is allowed to adjust itself naturally, without any packing. The settled weight is obtained by packing the powder through the process of rocking, shaking, turning, and jarring the gravimeter on a cradle, shown in the figure, and adding gradually to the contents, as a space is made by the packing together of the grains. In either case, when weighed, the gravimeter must be level full. This is shown by placing a pane of plate-glass over its top, and noticing whether it touches the rim of the gravimeter all around, and also if the powder is up to the surface of the glass all the way across. The only value attached to the use of a gravimeter is that of obtaining a tolerably correct idea of the volume of the air-space in any given weight. The air-space is dependent on the shape and size of the granules, and on the amount of settling or shaking together to which the powder is subjected. Knowing the specific gravity of the powder under examination, the air-space is found as follows: If w = the weight in ounces of 1 cubic foot of homogeneous powder, or the specific gravity multiplied by 1000, and w' = the weight in ounces of 1 cubic foot of same powder granulated, or the ascertained gravimetric density; then $\frac{w'}{w}$ = P is the proportion or per cent of the cubic foot occupied by the powder, and 1 — P = p is the proportion or per cent of the cubic foot occupied by air. These percentages are determined for the powder, both loose and settled. See *Inspection of Powder.*

GRAVITY.—Projectiles and all other bodies, when raised into the air and left unsupported, fall to the earth in lines perpendicular to it. The force which causes them to do so is termed gravity, and acts towards the earth's center; more strictly, it acts perpendicularly to the surface of still water. But if a projectile be projected obliquely into the air, it is made to describe a curved path, having a highest point, vertex, or apogee; and when it meets the earth in its descent, its direction is not towards the center, but inclined to it at the angle of projection. Observing this, and that the body, if not interrupted by the earth's surface, would continue to move in a curve, with its tangent always away from the center, it is easy to imagine that if not interrupted it might circulate round the center as the moon does round the earth. Next, knowing that the force of gravity is exerted at all accessible heights above the earth, the question arises—May it not be exerted as far off as the moon, which we know to be influenced by *some* force which continually deflects her from the tangent to her orbit, and makes her circulate round the earth? Observing now the time of revolution of the moon, and calculating its centrifugal force, which we know must equal the centripetal force, we put the question, Is this force the same as gravity? The answer is that it is a force 3600 times less energetic. If, then, gravity be the force which really holds the moon to her path, it must be explained why it acts upon her so much more feebly than it would were she a body on the earth's surface. The explanation is given at once if we suppose gravity to be a force whose energy diminishes with increase of distance, and is inversely as the squares of the distances at which it is exerted; for the distance of the moon from the earth's center is just about 60 times that of the earth's surface from its center, and 3600 : 1 : : 60^2 : 1. We infer that it does so from the fact that there is nothing inadmissible in such a diminution of energy with increase of distance—that, on the contrary, there are many analogies for it, as in the emanations of light and heat; and in the argument drawn from the necessity of otherwise supposing some other force than gravity to be employed in deflecting the moon, and the force of gravity to cease at some unknown level. On these views, and a generalization to be afterwards mentioned, Newton is understood to have at first rested his law of universal gravitation: "Every particle of matter in the universe attracts every other particle with a force directly proportioned to the mass of the attracting particle, and inversely to the square of the distance between them"—a law the truth of which, since it was first broached, has been put beyond all question by the most complete body of predictions, fulfilled to the letter, that can be cited in support of any law of nature.

Before, however, the argument on the extension of terrestrial gravity to the sphere of the moon could have become pregnant with so great a result, much investigation had to take place in other fields; and, in fact, Newton had, previously to conceiving the law, explained the three great Keplerian laws of order obtaining in the solar system by reference to an attractive force residing in the sun. These laws are—1. That the planets revolve round the sun in ellipses, having the sun for a common focus; 2. That every planet moves in such a way that the line drawn from it to the sun sweeps over equal areas in equal times; 3. That the squares of the times occupied by the several planets in their revolutions in their elliptic orbits are proportional to the cubes of their mean distances from their common focus, the sun. From the law of equal areas, Newton inferred that every planet is retained in its orbit by a force of attraction directed towards the center of the sun; from the orbits being elliptical, he inferred that in each case this force varies in intensity according to the inverse square of the body's distance from the sun; while from the third law he inferred the homogeneity of the central force throughout the solar system. It was then, after being familiar with the notion of terrestrial gravity and its action, through the researches of Galileo, Huyghens, and Hooke, and with the notion of a central force acting inversely as the square of the distance of its object, through his explanations of the laws of Kepler, that he put to himself the question,—Is not the force with which the moon gravitates to the earth the same with gravity?—the force which causes a stone to fall on its surface. A question answered affirmatively on the supposition of gravity, like the sun's attraction, being a force diminishing with increase of distance, and according to the same law. The result was to bring the whole solar system, the planets and the sun, and satellites and their planets—the satellites being observed to obey the same laws of order with reference to their primaries that the latter obeyed in reference to the sun—under the law of gravitation. And the imagination, lifted up by the grandeur of the conception, would refuse to limit the operation of that law to our own system, were there no facts to entitle us to extend it beyond. The phenomena of double stars, however, of themselves justify the extension and the statement of the law as we have given it in universal terms. It may be observed, in conclusion, that the Keplerian laws, which may be said to have been the basis of Newton's researches, are, owing to perturbations caused by the mutual action of the planets, etc., only approximately correct; and that these perturbations afford, when examined, a further proof of the truth and universality of the law of gravitation. See *Central Forces*, *Falling Bodies*, *Force*, and *Trajectory*.

GRAY CAST-IRON.—This variety of cast-iron is softer and less brittle than white iron; it is in a slight degree malleable and flexible, and is not sonorous; it can be easily drilled and turned in the lathe, and does not resist the file. It has a brilliant fracture, of a gray or sometimes a bluish-gray color; the color is lighter as the grain becomes closer, and its hardness increases at the same time. A medium-sized grain, bright gray color, lively aspect, fracture sharp to the touch, and close, compact texture indicate a good quality of iron. A grain either very large or very small, a dull, earthy aspect, loose texture, dissimilar crystals mixed together, indicate an inferior quality. Gray iron melts at a lower temperature than white iron, becomes more fluid, and preserves its fluidity longer; it runs smoothly; the color of the metal is red, and deeper in proportion as the heat is lower, it does not stick to the ladle; it fills the mould well; contracts less; and contains fewer cavities than white iron; the edges of a casting are sharp, and the surface smooth, convex, and covered with carburet of iron. Gray iron is the only kind suitable for making castings which require great strength, such as cannon. Its tenacity and specific gravity are *diminished* by slow cooling or annealing. See *Cast-iron.*

GRAZE.—The point at which a shot strikes and rebounds from earth or water. A *grazing-fire* is that which sweeps close to the surface it defends.

GRAZING RICOCHET.—The description of *ricochet* fire, when the *angle of fall* does not exceed 4°. In this fire the ball is given a great velocity, and the curve described is long and flat.

GREAT BRITAIN.—The Arms of the United Kingdom of Great Britain and of Ireland are borne by her Majesty Queen Victoria. Quarterly, first and fourth gules, three lions passant gardant in pale, or, for England; second, or, a lion rampant within a double tressure flory counterflory gules, for Scotland; third, azure, a harp or, stringed argent, for Ireland; all surrounded by the garter. *Crest.*—Upon the royal helmet, the imperial crown proper, thereon a lion statant gardant or, imperially crowned, also proper.

Royal Arms of Great Britain.

Supporters.—Dexter, the lion rampant gardant or, crowned as the crest. Sinister, a unicorn argent, armed crined, and unguled or, gorged with a coronet composed of crosses pattée and fleur-de-lis, a chain affixed thereto, passing between the fore legs, and reflexed over the back, also or. *Motto.—Dieu et mon Droit* in the compartment below the shield, with the union rose, shamrock, and thistle ingrafted on the same stem. Arms have been ascribed by heralds to the Saxon and Norman Monarchs of England in the tenth and eleventh centuries; but as Heraldry was, in point of fact, unknown till the middle of the twelfth century, they must be dealt with as fabulous. However, at a period almost before the earliest dawnings of hereditary coat-armor, the Sovereigns of England, in common with various other Monarchs of Christendom, adopted the lion as their device. Richard I., in his earliest seal, has two lions, which are borne counter-rampant; but in the latter part of his reign, after his return from the Third Crusade, the great seal of Cœur-de-lion represents the three lions in pale and passant gardant, as they have been almost uniformly depicted since. The only subsequent instance of which we are aware of any variation in the number is on a seal of the Carmelites at Oxford, in which Edward III. is represented in the surcoat charged with four lions in pale passant gardant, a proof of the latitude which heralds occasionally allowed themselves as late as the beginning of the fourteenth century. In 1340, Edward III., in virtue of the supposed right of his mother, assumed the title of King of France, and quartered the Arms of France with those of England, giving to the former the precedence. The fleurs-de-lis were then generally borne *sans nombre;* but in the latter part of the reign of Henry IV. they were reduced to three, borne or on a field azure. No further change took place in the royal escutcheon until the time of James I., except that Mary, on her second great seal, made after her marriage with Philip II., impaled the Arms of Spain and England. James VI. of Scotland, on succeeding to the throne of England, quartered the Arms borne by preceding Sovereigns with those of Scotland and Ireland, the first and fourth quarters being France and England quartered as before, the second quarter the lion rampant of Scotland within the double tressure, and the third quarter the harp of Ireland. The Royal Arms were similarly borne by all the Sovereigns of the House of Stuart till the reign of Anne, except that William III. bore over all the coat of Nassau on an escutcheon of pretense. In the reign of Anne, the legislative union with Scotland brought about a material change. England and Scotland impaled were placed in the first and fourth quarter, France in the second, and Ireland in the third. The accession of George I. displaced England and Scotland from the fourth quarter, to make way for the Arms of his Majesty's German dominions. A further alteration took place on the union with Ireland, when George III. laid aside the titular assumption of King of France, and abandoned the French ensigns. The Arms of England were now made to occupy the first and fourth quarter, Scotland the second, and Ireland the third, while the German ensigns were relegated to an escutcheon of pretense. These last were finally abandoned on the severance of Hanover from the Crown of Great Britain, which took place on the accession of Queen Victoria, and the royal escutcheon thus assumed its present arrangement.

From the union of the Crowns of England and Scotland under James I., up to the union of the Kingdoms in 1707, the Royal Arms were somewhat differently marshaled in Scotland, Scotland being allowed in all Scottish seals, ensigns, and Arms to occupy the first and fourth quarter, and England the second, while the whole were ensigned with the Crown of Scotland; but the Act of Union of 1707 recognizes no royal ensigns but those of the United Kingdom, which are to be "such as her Majesty shall think fit;" and on the union with Ireland, it was enacted that the armorial bearings of the United Kingdom "shall be such as his Majesty by his royal proclamation under the Great Seal of the United Kingdom shall be pleased to appoint." The practice, which prevails to a certain extent in Scotland, of giving the precedence to the Scottish lion in the royal shield, is incorrect, though the error has been committed in several of the official seals of the Kingdom.

The lion passant as the *crest* of England first appears on the Great Seal of Edward III.

The *supporters* borne in former times by the Kings of England varied much, particularly during the earlier period when these appendages of the shield were invested with more of a decorative than a heraldic character, and perhaps often left to the fancy of the engraver. When the Arms of any of the English Sovereigns from Richard II. to Edward IV. are represented with supporters, the animals selected are almost indifferently lions, antelopes, or white harts, and occasionally their place is supplied by angels. Edward IV.'s shield is sometimes supported on one side by a black bull, and Richard III.'s in one instance—in a MS. in the British Museum—on both sides by white boars. During the reigns of Henry VII. and Henry VIII., Edward VI., Mary and Elizabeth, the lion, red dragon, and greyhound were the supporters most in vogue, and as the herald or engraver had it not in his power to represent all three at once, he seems to have been allowed to select any two at pleasure. James I. for the first time clearly defined the royal supporters, adopting the lion of

England and unicorn of Scotland as they have ever since been borne, the unicorn having been, up to 1707, allowed precedence in Scotland. See *Arms*.

GREAT-COAT.—The overcoat issued to enlisted men. In the United States army it is of sky-blue cloth, double-breasted, or single-breasted with the additional cape; the linings and facings conforming to the trimmings of the uniform. On the frontier and campaign, officers may wear the soldier's great-coat with insignia of rank on the sleeve. See *Overcoat*.

GREAT CULVERIN.—A cannon of the French artillery, under Henry II., carrying a projectile weighing from 15 lbs. 2 ounces to 15 lbs. 4ounces.

GREAT FORTIFICATION.—One of the divisions of the first system of Vauban. It consists in a fortification whose exterior side is from 185 to 260 toises, or from 370 to 520 yards, and is seldom adopted but towards a river or a marsh.

GREAVES.—Pieces of armor formerly used as a defense for the legs (in the patois of Burgundy, *grève* still signifies "shin"). They were originally made of leather, quilted linen, etc., and afterwards of steel, hollowed out to fit the fronts of the legs, and fastened with straps behind. The Greeks termed them *knēmides* (whence the frequent expression in the *Iliad*, *euknēmides Achaioi*, or the "well-greaved Greeks"), and the Romans *ocreæ*.

GRECIAN ARMY.—Under a law promulgated in 1876, the military forces of Greece are divided into four parts—the Regular Army, the Regular Reserve, the Militia, and the Militia Reserve. All Greeks between 19 and 30 years of age, not serving in the Regular Army, are placed in the Regular Reserve; those from 31 to 40, in the Militia; and those from 41 to 50, in the Militia Reserve. The whole strength of the army under the bill is estimated at 200,000, 120,000 of whom belong to the Regular Army and its Reserve, 50,000 to the Militia, and 30,000 to the Militia Reserve. The number of the Regular Army is usually about 15,000. See *Army*.

GREEK BUCKLER.—This shield was distinguished by its two handles,—one in the center through which the arm passed, and one at the edge for the hand. In addition to this there was a leathern strap to hang the shield round the neck.

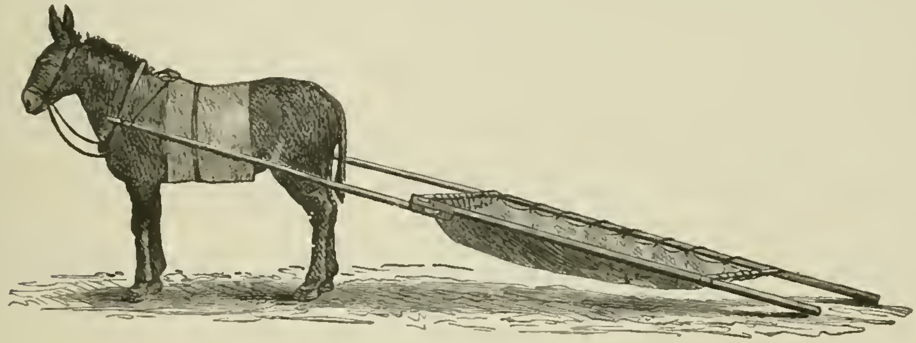
GREEK FIRE.—A composition supposed to have been of niter, sulphur, and naphtha as a principal ingredient, with which the Greeks of the Byzantine Empire were wont to defend themselves against their Saracen adversaries. The accounts of its effects are so mingled with obvious fable that it is difficult to arrive at any just conclusion as to its power; but the mixture appears to have been highly inflammable, and to have possessed the power of burning under water. It was projected either on blazing tow, tied to arrows, or through a tube, the precursor of cannon. Wherever the combustible fell, it made great havoc, from the inextinguishable nature of the fire. The invention of this material has usually been ascribed to Callinicus of Heliopolis, and the year 668 A.D.; but there seems to be reason to believe that it was rather imported from India. At Constantinople, the process of making Greek fire was kept a profound secret for several centuries. The knowledge, however, of its composition gradually spread; and at the time of the discovery of gunpowder, Greek fire formed a recognized defensive element in most wars from western Europe to Asia Minor. Subsisting for some time concurrently with gunpowder, it gradually died out before the advances of that still more effective competitor, till now little vestige remains of Greek fire beyond a Norman corruption of its name in our fire-work "Cracker," which, derived from "Creyke" of the Middle Ages, is but a corruption of "Grecque."

GREEN CHARGE.—In the manufacture of gunpowder certain processes have to be carried out, the primary one being that of "mixing the ingredients" after they have been weighed and brought into contact previous to being incorporated. The process of *mixing* is performed by putting the composition into a cylindrical gun-metal or copper drum, about 2 feet in diameter, with an axle passing through its center, on which there are metal flyers like forks; the machinery is so arranged that the flyers and drum revolve in opposite directions, at a rate of about 100 revolutions a minute; five minutes is long enough for a thorough mixture; the charge is then drawn off by a slip into a canvas bag capable of holding a 50-lb. charge, which is tightly tied and removed to a small magazine until required for the incorporating process. In this form it is called a *green charge*.

GREENE GUN.—A breech-loading rifle, having a fixed chamber closed by a movable breech-block which slides in the line of the barrel by direct action. This piece has a concealed spiral-spring lock. It is loaded through a mortise cut in the side of the receiver, and is locked by projections on the bolt engaging with corresponding cavities in the receiver. The handle of the breech-bolt is so formed as to lie close to the stock, when turned down and closed. A detachable magazine or pannier, made of tin, can be connected with the right side of the receiver, and is worked by canting the gun to the left, and allowing a cartridge to roll into the receiver in front of the bolt, when it is withdrawn to load.

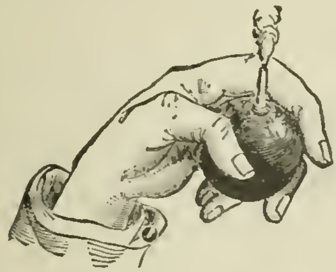
GREENER BULLET.—About 1836 Mr. Greener invented and submitted for trial at Tynemouth, under the authority of the Master General, and Board of Ordnance, a bullet to expand by the action of the powder. It was shaped like an egg, having an opening at one end to receive a taper plug, with a head like a round-topped button, of a composition of lead, tin, and zinc. This plug, which was rather larger near the head than the opening, was driven home on the explosion of the powder, when the sides of the bullet were dilated, and forced into the grooves of the rifle, thereby stopping all windage, and increasing the accuracy of shooting as compared with the Government bullet. The Board of Ordnance rejected this bullet on the ground of its being compound; in 1857, however, Mr. Greener was awarded £1000 "for the first public suggestion of the principle of expansion, commonly called the Minié principle, for bullets, in 1836."

GREENLEAF LITTER.—A combination horse and hand-litter, constructed after the plan of the Indian *travail*. It consists of four ash poles, two for shafts and two for litter-poles; the former are $7\frac{1}{2}$ feet long, 2 inches wide, $2\frac{3}{4}$ inches deep at the butt, and $1\frac{3}{4}$ by $1\frac{3}{4}$ inches at the point; the latter are $8\frac{1}{2}$ feet long, 2 inches wide, and $2\frac{3}{4}$ inches deep, with rounded edges and corners. On one end of the litter-pole are riveted two wrought-iron bands $\frac{1}{8}$ inch thick and $1\frac{1}{2}$ inch wide. One of these collars is set 2 inches from the end of the litter-pole, and has a diameter of $4\frac{5}{8}$ inches by 2 inches; the other is set 12 inches from the end of the poles, and has a diameter of $5\frac{5}{8}$ by 2 inches. The opposite end of the litter-pole is shod with an iron thimble 1 foot long. Two cross-bars, 30 by $1\frac{1}{4}$ by $2\frac{1}{4}$ inches, with a square collar of iron $\frac{1}{8}$ inch thick by $1\frac{1}{2}$ inch wide on each end, serve to keep the poles separated and steady; the collars should have a diameter of 2 by $2\frac{3}{4}$ inches, and the litter-pole must be square at its front end and $2\frac{1}{2}$ feet from the rear end for their reception. A canvas bed 6 feet by 32 inches, with strongly bound eyelets 8 inches apart on the upper end and upper three feet of the sides, and permanently fastened to the lower three feet of the sides, completes the affair. The litter is dragged by a horse or mule hitched into the shafts,—the rear ends of the litter-poles resting on the ground, the patient occupying the canvas bag in the middle. To put it together, the small end of the shaft is passed from behind forward, through the rear and larger collar on the front end of the litter-pole, thence through the smaller collar, and then "pulled home," until the butt of the shafts is tightly embraced by the collars; the cross-bars are then put into their respective places by slipping their collars over the front and rear ends of the litter-poles and pushing them securely home, the canvas bed lashed to the poles by ropes passing through the side eyelets and around the poles, and through the end eyelets and around the cross-bars; the ropes at the head of the bed should be slack, to afford "bag" enough to the canvas to bring the head and shoulders of the patient nearly on a level with his feet. By the arrangement of splicing the shafts to the litter-poles through collars of unequal sizes, a constant tightening of the parts goes on by the force exerted by the animal in pulling the litter, and no opportunity for loosening occurs; while as the greatest weight occurs at this point, additional strength is gained through the iron collar and the double thickness of pole. With a collar and harness, which can be carried without much trouble, the litter can be hitched to an animal by a chain attached to the harness, and having on its end a goose-neck pin to pierce the shaft from below, and be fastened above by a nut or linch-pin. To unship the latter, give a smart blow on the small end of the shaft which will drive it back through the collars, when it can be taken out; remove the cross-bars, unfasten the ropes, and wrap the poles and cross-bars in the canvas, packing the whole thing like a tent on a pack-mule. For use as a hand-litter, it is only necessary to unship the shafts. See *Litter*.



Greenleaf Litter.

GRENADE.—A small shell, about three inches in diameter, of iron or annealed glass, filled with powder, and thrown from the hand. Hurled among dense masses of troops, as those assembled in the ditch of a fortress during an assault, grenades are particularly embarrassing, the splinters inflicting deep wounds and causing great confusion. The discharge is effected by means of a small time-fuse. Grenades are occasionally rolled over the parapet, through wooden troughs, into the trench below; there is also a species of hand-gun fired from a rest, called "musketon," from which grenades may be projected to a short distance. These missiles are said to have been first used in the year 1594. See *Hand-grenade, Projectiles, Rampart-grenade,* and *Shells*.



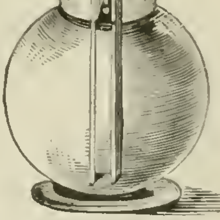
Hand-grenade.

GRENADIER.—Originally a soldier who was employed in throwing hand-grenades, but in modern parlance a member of the first company of every battalion on foot, in which the tallest and finest men of the regiment are placed. This company used to be distinguished from the rest by tall bear-skin caps; it holds the place of honor, viz., the right, when in line, and the front when in column of attack.

GRENADIER GUARDS.—The first regiment of foot-guards in the British Household Brigade of Guards, and generally considered the finest corps in the army. It comprises 2540 officers and men, divided into three battalions. The officers of this fashionable corps are usually from the families of the nobility or more distinguished landed gentry. The First Foot-guards, under which name the regiment was originally known, was first raised in 1660; since then it has ever borne an honorable position in all the wars of the country, and especially in the Peninsula, at Waterloo, and in the Crimea.

GRENADIERS AUXILIARIES.—During the siege, and when a place was closely invested, a certain number of grenadiers were chosen out of the battalions belonging to the trenches, for the purpose of making headway against the besieged, whenever they might risk a sally, or assault the works. It was the peculiar duty of these men to stand forward on every occasion, to set fire to the gabions attached to the batteries, and to crush every attempt which might be made by the garrison to annoy the men that were posted in the trenches, etc.

GRENET BATTERY.—A variety of battery much used for military purposes. It occupies but little space, furnishes an immense quantity of current, is beautiful in design, and, as the zinc can be raised from the fluid, may be kept charged, ready for use, for many months, and can be set in action any time when required, by simply depressing the rod of brass which slides through the center of the cover of the cell, and to which the zinc is attached. For operating induction-coils and electro-medical instruments it is unequaled.



Grenet Battery.

To Make the Solution.—To three pints of cold water add five fluid ounces of sulphuric acid. When this has become cold, add six ounces (or as much as the solution will dissolve) of finely pulverized bichromate of potassa. Mix well.

To Charge the Battery.—Pour the above solution into the glass cell until it nearly reaches the top of the spherical part, then draw up the zinc, and place the elements in the cell. The fluid should not quite reach the zinc when it is drawn up.

Where it is designed to have a battery for occasional service, such as is needed for operating large induction-coils, electric-light experiments, charging large magnets, and for general laboratory work, the plunge-battery is probably the most efficient and convenient yet devised. When not in use the plates are lifted from the solution, but are always ready at a moment's notice. The fluid used is that of the Grenet battery. The plates can be readily detached and replaced at slight expense when necessary, and the jars easily emptied, cleaned, and refilled without taking the plates apart, which, together with the crank-lift, make this battery one of the most convenient ever devised for the purposes to which it is adapted.

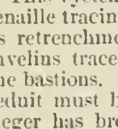
GREVIERES.—Pieces of armor for the protection of the legs and thighs. See *Trumelières*.

GRIBEAUVAL SYSTEM OF ARTILLERY.—About 1765, various improvements were introduced into European artillery by General Gribeauval. He separated *field* from *siege* artillery, lightened and shortened field-guns, and diminished the charges. He adopted elevating-screws, strengthened the carriages, and introduced neater uniformity in the dimensions, enabling spare parts to be carried for repairs. See *System of Artillery*.

GRICES.—A term used in Heraldry to signify the young wild-boars. See *Heraldry*.

GRIENDEL D'ACH SYSTEM OF FORTIFICATION.—This system is a combination of the bastion and tenaille tracings. The enceinte is bastioned and serves as retrenchment; the tenailles are formed of great ravelins traced on the prolongation of the faces of the bastions. The four flanks of the ravelin and its reduit must be destroyed by the mine when the besieger has breached the ravelin. The ditch of the reduit is defended by a double flank constructed on the face of the bastion. Between the tenailles are ravelins with long flanks. The outlay is very great, and the place is much exposed to enfilade.

GRIFFIN.—A chimerical creature, which the fancy of the modern has adopted from that of the ancient world. The griffin is first mentioned by Aristeas, perhaps about 560 B.C., though the accounts of Aristeas seem to be about as fabulous as those of the griffin. The origin of those monstrous conceptions in general, of which the griffin is one, has already been considered under DRAGON. The griffin is variously described and represented, but the shape in which it most frequently appears is that of an animal generated between a lion and an eagle, having the body and legs of the former, with the beak and wings of the latter. In this form it appears on antique coins, and as an ornament in classical architecture. Like all other monsters, griffins abound in the legendary tales of the Teutonic nations, and the name in various forms, slightly differing from each other, is to be found in most Teutonic dialects. Whether in the two cases both the name and the notion might not be traceable to a common source, or whether it was through barbarian or classical channels that they found their way into the nomenclature and the practice of heralds, are subjects on which we do not venture an opinion. Certain it is, however, that there are few fabulous conceptions with which the science of Heraldry is more conversant than the griffin. Nor were they regarded by the patriarchs of that science always as mere creatures of the imagination, for, incredible as it may seem, we find Gerard Leigh, a herald of great reputation in the time of Elizabeth, talking of them with entire sincerity as existing animals. "I think they are of great hugeness," he says, "for *I have a claw of one of their paws*, which should show them to be as big as two lions." In the heraldic griffin, the claws of the eagle are usually substituted for the fore-paws of the lion. Gwillim blazons a griffin in this attitude "rampant," alleging that any fierce animal may be so blazoned as well as a lion. But the more appropriate and usual term is "segreant." In representing the griffin, the ears ought not to be omitted, as they indicate the attribute of watchfulness, which, along with strength and swiftness, went to make up the classical conception of his character. See *Wyvern*.



Griffin.

GRIFFIN GUN.—A name sometimes given to the 3-inch rifle used in the United States field-service, from its inventor, Mr. Griffin, of the Phœnixville Iron-works, Pennsylvania, where the gun was made.

GRINDING-MACHINE.—The use of emery grinding-machines in almost every branch of accurate machine construction is extending every year. Wherever exact cylindrical forms or true plane metal surfaces are required, emery-wheels have been found to be the most effective means of supplementing the work of the lathe and planing-machine in producing exact work. Sir Joseph Whitworth was among the first to develop the true surface-plate system, which he arrived at by scraping the surface and correcting the errors and inequalities by fitting the plates to each other. Two plates may be made to fit each other perfectly and neither be a true plane, because one may be convex and the other concave to correspond; but if one plate is fitted to two others and the latter are both convex or concave, they will not fit each other. Latterly, however, true surfaces are reproduced by moving an object on a perfectly true plane or table over a grinding-wheel in the middle which removes all the projections of the object, and in this way the perfect plane of the table is, so to speak, transferred to the object.

The machine shown on page 787 is intended to produce perfectly true wearing surfaces on various work in this way. The engraving illustrates its construction so clearly that little or no description is needed. The distance from the floor to the center of the spindle is 27 inches. The latter is of steel, 2 inches in diameter, and two- or three-cone pulleys are furnished as may be required. The machine is intended for emery-wheels of 20 inches diameter and 4 inches face, which it will wear down to 9 inches in diameter. The plate for the surface-grinding is 5 feet long and 11 inches wide, and can be elevated and lowered. These machines, in great numbers, are employed in arsenals. See *Emery-grinder*.

GRIP.—1. In some guns the bore is slightly enlarged to within about a caliber in front of the shot-chamber; the intervening portion, which has a less diameter than any other part of the bore, is termed the *grip*. The diameter of this *grip* is the *caliber* of the gun. 2. The handle of a sword.

GRIPES.—A complaint with which horses are often attacked; the remedy recommended is as follows: On the horse being observed to be in pain, he should be trotted about until his bowels are emptied. Should this fail, he must be bled to the extent of two or three quarts, and a ball composed of one drachm of gum opium and two of powdered ginger, made up with bruised meal, given to him, and a clyster of oatmeal gruel every two hours. See *Veterinary Art*.

GROGNARDS.—A term applied to the old soldiers of the French Empire, who were noted for grumbling.

GROINED VAULTING.—In fortification and building, that kind of vaulting in which the vault is not a plain barrel-vault from end to end, but where one vault cuts into another. The angle formed by the intersection is called the groin. In Roman architecture the groins were generally left as a plain sharp edge; in Gothic, they were usually protected and strengthened with *ribs*.

GROMA.—A Roman measuring-rod, about 20 feet long, used for setting off distances in a camp.

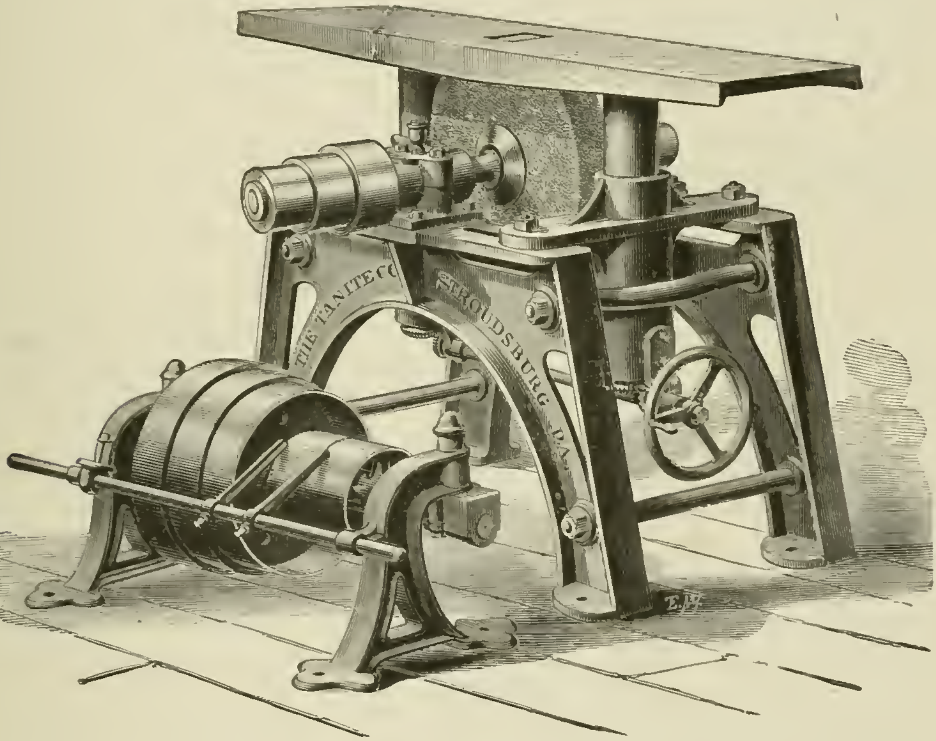
GROMMETS—GRUMMETS.—Circular pieces of rope attached to shot to keep the shot steady in the bore. They are made of various sizes. Grummet-wads are also used when firing at angles of depression, or at angles of elevation less than 3°; the grummet is placed over the shot to prevent it from running out of the piece. The use of grummet-wads with rifled muzzle-loading guns has been discontinued for land-service, except when these guns are firing at a depression. The term *grummet* is applied to a rope ring worked in a particular manner. See *Wad.*

GROOM.—One of several officers of the English Royal Household, chiefly in the Lord Chamberlain's Department; as, the Groom of the Chamber; Groom of the Stole, or Robes.

GROOM-PORTER.—An officer in the Household of the King of England, who succeeded the Master of Revels, and gave directions as to sports.

GROOVES.—The width of the groove generally depends on the diameter of the bore and the peculiar manner in which the groove receives and holds the projectile. Wide and shallow grooves are more easily filled by the expanding portion of a projectile than those which are narrow and deep; and the same holds true of circular-shaped grooves when compared to those of an angular form. An increase in the number of grooves increases the firmness with which a projectile is held, by adding to the number of points which bear upon it. The effect of decreasing the depth of rifle-grooves is, generally, to increase the accuracy but diminish the range. The increase of accuracy undoubtedly arises from the fact that the projectile is held more firmly by the grooves as it passes along the bore; while the diminution of range arises from an increase of friction between the projectile and the grooves. The comparative advantages of uniform and variable grooves depend on the means used to connect them with the projectiles. If the bearing of the projectile in the grooves be long, and the metal of which it is made be unyielding, it will be unsafe, if not impracticable, to employ variable grooves; and if the metal be partially yielding, a portion of the force of the charge will be expended in changing the form of that part of the projectile which projects into the grooves, as it moves along the bore. When the portion in the grooves is so short that its form will undergo but slight alteration, the increasing groove may be used with advantage, as it diminishes the friction of the projectile when it is first set in motion, and thereby relieves the breech of the piece of a portion of the enormous strain which is thrown upon it. If the twist be too rapid toward the muzzle, there will be a danger of bursting the piece in the chase. It is claimed by some that the variable groove is well adapted to expanding projectiles with short bearing surfaces; but the uniform groove, being more simple in its construction, and nearly as accurate in its results, is generally preferred for military fire-arms, both large and small.

The width of a groove depends on the diameter of the bore, and on the peculiar manner in which the groove receives and holds the projectile. Wide and shallow grooves are more easily filled by the expanding portion of a projectile than those which are narrow and deep; and the same holds true of circular-shaped grooves, when compared to those of angular form. An increase in the number of grooves increases the firmness with which a projectile is held, by adding to the number of points which bear upon it. It has been suggested that rifle-cannon, intended for flanged projectiles, should have *four* grooves; as a greater number increases the difficulties of loading, and a lesser number does not hold the projectile with sufficient steadiness. For expanding projectiles, an odd number of grooves is generally employed, for, as this places a groove opposite to a *land*, less expansion will be required to fill them. The number of grooves used in the 3-inch field-gun is *seven*, and the number used in 4½-inch siege-guns is *nine*. The number of grooves in the 4-inch Armstrong gun is *fifty*.



Emery Grinding-machine.

The object of rifle-grooves being to communicate an effective rotary motion to a projectile throughout its flight, it remains to determine what velocity of rotation, or inclination of grooves, is necessary for different projectiles. The velocity of rotation will depend on the form and initial velocity of the projectile, the causes which retard it, and the time of flight; therefore *there is one particular inclination of grooves* *which is best suited to each caliber, form of projectile, charge of powder, and angle of fire.* It has been noticed that if very long projectiles be fired from the rifle-musket, they are less accurate than the ordinary projectile, the length of which is less than two calibers. Mr. Whitworth states that he has known a bullet twice this length turn over end for end within six feet of the muzzle of the English rifle-musket, the caliber of which is nearly the same as that of the American rifle-musket. This instability undoubtedly arises from the want of sufficient rotation around the long axis. What increase of angular velocity must, therefore, be given to compensate for a given increase of length of an oblong projectile?

The resistance which a projectile offers to angular deflection, when rotating around a *principal* axis, is proportional to the moment of its quantity of motion taken with reference to this axis, or M k^2w, M being the mass, k the radius of gyration, and w the angular velocity. Let this expression represent the moment of the quantity of motion around the long axis, and k_1 and w_1 the radius of gyration, and angular velocity, around a short axis, and suppose the angular velocity w and w_1 to be such that the resistance to a deflection from the axes shall be equal: we have $M k^2 w = M k_1^2 w_1$, and by reduction $w_1 = \frac{k^2}{k_1^2} w$. Hence, if we determine by experiment the value of w, the angular velocity necessary to give *practicable* stability of rotation, we can determine the value of w_1, and consequently the superior limit of the deflecting forces. Substituting the value of w_1 in a similar expression for any other projectile, we can determine the angular velocity, and from this the inclination of grooves necessary to give the second projectile steadiness in flight.

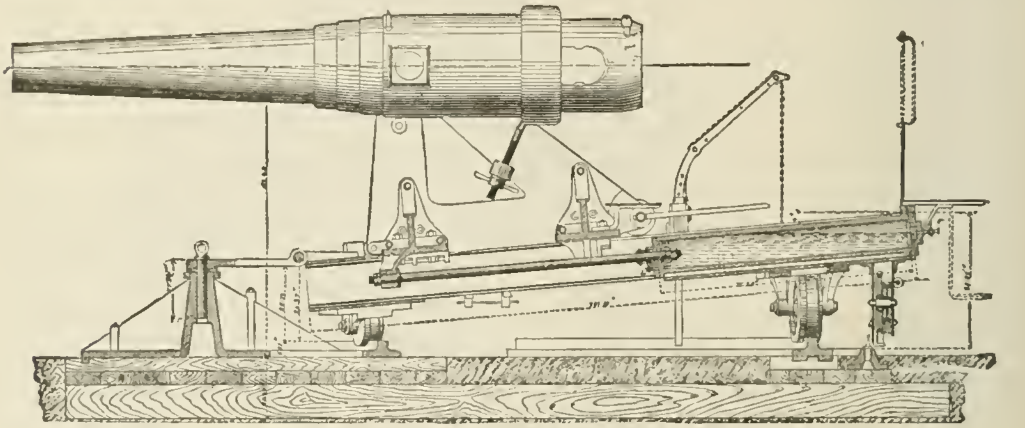
The foregoing method of determining the relation between the lengths of two rifle-projectiles, and the inclination of grooves necessary to give them equal steadiness of flight, is true only under the supposition that they preserve throughout their range the relative angular velocities with which they started. It is necessary, therefore, to consider the causes which affect rotation. The inclination of grooves for a rifle-cannon best suited to a given projectile has not yet been determined by experience; and the consequence is that a wide diversity of "twists" is employed in the various services, and by different experimenters. Colonel Cavalli, in his experiments in Sweden, obtained good results from twists of one turn in 12 feet, and one turn in 35 feet, in a 32-pdr. gun; and a still greater variety of twists have been employed in our own service. For a projectile one and a half diameters long, and 6-pdr. caliber, excellent practice has been obtained with a twist of 25 feet; and in a certain form of the Armstrong gun the twist is 12 feet for a bore 4 inches in diameter. See *Increasing Twist, Twist,* and *Uniform Twist.*

GROS.—Any body of soldiers; a detachment. The French frequently say, *Un gros d'infanterie,* a body of infantry.

GROUND.—A common term in military phraseology, meaning the field or a place of action. What is termed *taking ground* is the extension of a body of troops in any direction. To *gain ground* is to advance; to *lose ground* is to retire or retreat.

GROUND ARMS.—An old word of command, directing the soldiers to lay down their arms upon the ground. It is omitted from the present tactics.

GRUSON SEA-COAST CARRIAGE.—Carriages for guns of 8-inch caliber only have been furnished by Gruson. They differ from the corresponding carriages made by Krupp in this essential particular, that cast-iron is used for several of the important parts in place of cast-steel or wrought-iron, and in consequence a cheaper but heavier carriage is made. The 8-inch guns are of two distinct classes, differing from each other in the distance between the rimbases, being 35 inches and 25.3 inches respectively, and requiring separate carriages. The top-carriage consists of two cheeks of cast-iron, each in one single piece, with a rib on the outside extending around the edge and forming on the lower side a shoe which slides on the rail. The cheek is cut out in the middle to make it lighter, and is reinforced with a rib around the edge of the hole thus formed. The cheeks are connected together by two cast-iron transoms, front and rear, at right angles to the shoe, each held in place by two pins and three bolts. The spaces between the ends of the transoms and the cheeks are filled up with melted zinc, and whenever two pieces of cast-iron are connected together without planing the surfaces, melted zinc is poured into the space between them. The front transom has a cross-head cast to it on its under side to operate the piston-rod, and guides to direct the motion of the top-carriage on the rails. Guide-hooks are bolted on the under side of this transom to prevent any vertical motion of the top-carriage and the bending of the piston-rod. A sheet-iron step rests on two brackets which are bolted to the cheeks in rear of the rear transom, for the man to stand on who elevates or depresses the gun. The rib on the outside of the cheek forms a recess at the front and rear corner for the truck-wheels, which are made of cast-iron bushed with white metal, and provided with lubricating-holes. The axle of the front roller is bolted to the cheek. The rear rollers are slightly larger than the front ones, and are mounted on an eccentric axle. The portion of the axle which passes through the cheek is made larger than the rest and has a circular slot extending about a quarter of the



Gruson Sea-coast Carriage.

circumference around it. A screw set in from the rear end of the cheek plays in this slot and acts as a stop to limit the turning of the axle, and also to prevent it from moving in the direction of its length. There is a hole in the axle on the inside of the cheek for the end of a handspike by which to turn the axle and throw the rollers in or out of gear. The elevating-apparatus consists of a strong screw pivoted on a shaft secured to the left cheek, and a female screw of brass which is operated by means of four handles cast to the lower part of the female screw. India-rubber rings are interposed between the female screw and box to lessen the force of the shock of the recoil on the screw-box. The top-carriage for the smaller gun differs from that just described in this, that the cheeks are bent outwards at the bottom to preserve the same distance between the shoes in the two carriages, so that the same chassis may be used for either, and in having a different elevating-apparatus. The preponderance of these guns, 992 pounds, allows the application of a single elevating-screw under the breech of the gun, a female screw being fitted in a boss on the rear transom. In order to obtain high angles of elevation without having a screw of very great length, a cast-iron cap is placed on the head of the screw between it and the gun, and is kept there for all angles of elevation less than 8°, which corresponds to a range of 3280 yards.

The rails are 12-inch rolled beams, connected together by three transoms of boiler-plate, two at the front and one at the rear end. Wooden hurters are secured to the front end of the rails for the front truck-wheels to strike against. India-rubber counter-hurters are secured to the box-flange of the hydraulic cylinder, and are struck by the guides on the rear transom of the top carriage. The hydraulic cylinder is of cast-iron, 75 inches long and 1.4 inch thick. It has a flange or seat cast on the bottom at each end for securing it to the bottom transom. The rear seat takes the form of an open box, the length equal to the distance between the rails to which it is bolted, as well as to the bottom transom. The ends of the cylinder are turned off square, and are closed by cast-iron covers fitted closely and bolted to the cylinder, a piece of pasteboard saturated in linseed-oil being interposed between the surfaces to make a close joint. The front cover contains the stuffing-box, which is of brass. The rear cover has a recess in the inside, so that the nut on the end of the piston-rod shall not strike it. There is a gauge-cock in the center of this cover to regulate the height of the glycerine in the cylinder. The piston-head is of cast-iron. The four holes in it are reamed out to be parabolic in section; the least diameter is .78 inch. The traverse-wheels are of cast-iron; the front ones are solid and smaller; the rear have spokes. The sole is flat, and the front flange is much stronger than the rear one. The front flange of the rear wheel has holes in its periphery to receive the end of a handspike to traverse the chassis in case the traversing-gear should fail to operate. The traverse-wheel forks are also of cast-iron. The front fork has no rear branch, the wheel being supported only on the front side. The traversing-gear is held in a frame formed of two parallel iron plates bolted by means of angle-irons to the rear bottom transom. It consists of a large grooved wheel for the chain, and four guide-rollers; two with their axles horizontal are grooved like the large wheel; the others have their axles vertical. A large spur-wheel is shrunk on the nave of the chain-wheel, and is driven by a pinion and bevel gears on a cross-shaft which is turned by a crank. The projectile-crane consists of a crane-box of cast-iron bolted to the outside of the right chassis-rail. The crane proper is composed of two parts—the body, which is a round iron rod, and moves freely up and down in the circular hole in the crane-box, and the bent neck, made of two flat bars riveted to the flattened upper end of the body. The neck has two fixed pulleys between the flat bars for the chain to work over. A straight rack is secured to the body at their upper ends, the end of the former being bent at a right angle to itself, with a circular hole in the bent end for the body of the crane to pass through. A shoulder on the top of the body rests on the rack where the body passes through the bent end. The rack is operated by means of a wheel and pinion turned by a crank. A chain with a hook on each end is fastened at one end to the crane-box, passes over the two pulleys, hangs from the end of the neck, and is fastened to the projectile-cart. In raising the crane the projectile is also raised by the shortening of that part of the chain which hangs from the upper roller. The implements are the same as for Krupp's carriage, with the exception of the handspike, which is entirely of iron; and the traversing-gear has two cranks. The weights of the two carriages are as follows:

	Krupp's.	Gruson's.
	Pounds.	*Pounds.*
Weight of top-carriage	4,602	5,512
Weight of chassis	10,830	8,819
Total weight	15,432	14,331

See *Sea-coast and Garrison Carriages.*

GUARANTEE ASSOCIATION.—An Association in England which for a small percentage undertakes to vouch for the prudence and fidelity of such public officers as Paymasters, Ordnance Storekeepers, Commissaries, Staff Officers of Pensions, Barrack Masters, etc. The Government accepts the guarantee of this particular office in preference to that offered by private individuals.

GUARD.—1. A body of men whose duty it is to secure an army or place from being surprised by an enemy. Camp and garrison guards are relieved every twenty-four hours. The guards at outposts are ordinarily relieved in the same manner, but this must depend on their distances from camp, or other circumstances, which may sometimes require their continuing on duty several days. In such cases they are previously warned to provide themselves accordingly. All persons, of whatever rank in the service, are required to observe due respect toward sentinels. The *countersign*, or watchword, is given to such persons as are entitled to pass during the night, and to officers, non-commissioned officers, and sentinels of the guard. Interior guards receive the countersign only when ordered by the Commander of the troops. The *parole* is imparted to such officers only as have a right to visit the guards, and to make the grand rounds; and to officers commanding guards. Sentinels are relieved every two hours, unless the state of the weather, or other causes, should make it necessary or proper that it be done at shorter or longer intervals. Those at the guard-house or guard-tent are the first relieved and left behind. Each relief, before being posted, is inspected by the Commander of the Guard. The Corporal reports to him, and presents the old relief on its return. If the sentinels are numerous, the Sergeants are employed, as well as the Corporals, in relieving them. Sentinels do not take orders or allow themselves to be relieved, except by an officer or non-commissioned officer of their guard or party, the Officer of the Day, or the Commanding Officer; in which case the orders are immediately notified to the Commander of the Guard by the officer giving them. Sentinels report every breach of orders or regulations they are instructed to enforce.

2. A position in bayonet and saber exercises, executed as follows:

With the Bayonet.—Bring the left toe nearly to the front; carry the right foot three inches to the rear, the heel two inches to the right of the left, the feet at right angles. (Two.) Carry the right foot fifteen inches to the rear, feet at right angles, knees slightly bent, the body resting equally on both legs; at the same time bring down the piece into the left hand, the little finger at the lock-plate, thumb along the stock, the right hand at the small of the stock, the barrel turned slightly to the left, the butt three inches in front of the body and a little below the belt-plate, the point of the bayonet in front of and at the height of the chin, both arms half extended, the left elbow near the body. All movements in the bayonet-exercise, not specially excepted, are executed from guard, to which position the piece is restored after every movement by the command *guard*. The position is shown in Fig 1.

With the Saber.—Carry the right foot about two feet to the right, heels on the same line; place the left hand, closed, six inches from the body, and as

Fig. 1.

Fig. 2.

high as the elbow, the fingers toward the body, little finger nearer than the thumb (position of the bridle-hand); at the same time place the right hand in tierce in front of and a little higher than the right hip, thumb extended on the back of the gripe, little finger by the side of the others, the point of the saber inclined to the left, and two feet higher than the hand, which grasps the saber without constraint. The position is shown in Fig 2. To return to the *carry*, the Instructor commands: 1. *Carry*, 2. Saber. At the command *saber*, the recruits resume the position of the soldier, and come to the *carry*. See *Bayonet-exercise, Fencing*, and *Saber-exercise*.

GUARD-DETAIL.—The men from a company, regiment, or other organization detailed for guard-duty. The First Sergeant keeps the roster and makes this detail.

GUARD-DUTY.—In a general sense, that duty performed by a sentinel. This duty in peace is much more severe than is generally supposed, and usually requires that during the 24 hours of its continuance the sentinel shall make a march under arms of some 16 miles for one third of the time, and be "present for duty equipped" at a moment's notice always. If this happened once a week it would be often enough. Coming, as it does, twice or thrice, it imposes more labor and exposure than all other military duty, and year after year of it tells. There are two ways of meeting this trouble; one by relaxing the regiments of guard-duty to some extent, and one by enlarging the number of men upon whom it is imposed. Its proper performance, so far as security of buildings and stores is concerned, or even the restriction of travel to certain directions, does not require a full uniform or even a 14-pound musket. "To take charge of all public property in view," when nothing can be seen by the naked eye but a 20-ton gun and a chain pump, hardly demands that a man should pace majestically back and forth from one to the other forever. He would be just as useful if he carried a switch and came round at intervals; if, in fact, he dared to consider himself less of a sentinel and more of a watchman. In these days of telephones, when offices, stables, quarters, etc., can all be put into immediate communication with one another, and a man at his desk may in a moment summon into his presence, or receive a report from, anybody, whether a Police Sergeant or Post Surgeon, the time-honored formalities and display of guard-duty may well be relieved of much that is out of date and out of use. It can be made much less mechanical and tedious with no loss of value. See *Guard*.

GUARD-HOUSE.—The building occupied by the guard. The prisoners being kept in the building, it is frequently used as a synonym for prison-room or lock-up. *To take one to the guard-house* is to confine him. See *Guard-room*.

GUARD-MESS.—The table which is kept for the officers of the Life and Foot Guards in St. James's Palace. The sum of £4000 per annum is allowed for the Mess.

GUARD-MOUNTING.—The military ceremony of marching on guard. At the *assembly of guard-details*, the men warned for duty fall in on their company parade-grounds, in two ranks, facing to the right, non-commissioned officers and supernumeraries falling in as file-closers; each First Sergeant then faces his detail to the left, verifies it, fixes bayonets, brings the detail to rear open order, inspects the dress and general appearance, replaces by a supernumerary any man whose condition makes him unfit to march on guard, and then brings the detail to close order. The band takes post on the regimental parade, so that the left of its front rank shall be twelve yards to the right of the front rank of the guard when the latter is formed. At *adjutant's call*, the Adjutant and Sergeant-major march to the regimental or garrison parade, the Sergeant-major on the left; the details are conducted to the parade by the First Sergeants, the band playing in quick or double time. Upon arriving on the parade-ground, the Sergeant-major takes post facing to the left, 12 yards to the left of the front rank of the band; the Adjutant takes post so as to be 12 yards in front of and facing the center of the guard when formed. The detail which arrives first is so conducted to the line that, upon halting, the breast of the right front-rank man shall be near to and opposite the left arm of the Sergeant-major. The Sergeant having halted his detail, places himself in front of and facing the Sergeant-major, at a distance equal to or a little greater than the front of his detail; he then commands: 1. *Rear open order*, 2. March. At the second command, the ranks are opened, the front rank dresses up to the line of the Sergeant-major and First Sergeant, the right front-rank man placing his breast against the left arm of the Sergeant-major; the rear rank steps back and halts three yards in rear of the front rank; the non-commissioned officers three yards in rear of the rear rank; and the supernumeraries three yards in rear of the non-commissioned officers. Seeing the ranks opened, the Sergeant commands, Front; salutes the Sergeant-major, and reports: *The detail is correct*; or, (So many) *Sergeants, Corporals*, or *privates, are absent*. He then passes by the right of the guard, and places himself three yards in rear of his supernumeraries. The other details, as they arrive, form in a similar manner on the left of the first; each First-Sergeant places himself opposite the left of his detail, faces the Sergeant-major, opens ranks, salutes, reports, and places himself in rear of his supernumeraries as already prescribed; the rear rank, the non-commissioned officers and supernumeraries of each detail, dress on the rear rank, the non-commissioned officers and supernumeraries of the detail next preceding; the rear rank closes to the right. The company details alternate in taking the right of the line. The Sergeant-major returns the salutes with the right hand, draws his sword, verifies the details, causes the guard to count fours, completing the left four as in the School of the Company, if necessary, and then divides the guard equally into two platoons; after which he commands: 1. *Right*, 2. Dress. The Sergeant major verifies the alignment of the ranks, file-closers, supernumeraries, and First Sergeants, and then returns to the right of the front rank, faces to the left, commands, 3. Front, passes to the center of the guard, turns to the right, halts midway to the Adjutant, salutes, and reports: *Sir! The details are correct;* or, *Sir!* (so many) *Sergeants, Corporals*, or *privates, are absent*. At the order, *Take your post*, the Sergeant-major faces about, approaches to within two yards of the center of the guard, and, turning to the right, places himself facing to the front, three yards to the left of the front rank. The Sergeant major having reported, the Officers of the Guard post themselves facing to the front, three yards in front of the front rank, and draw sword, the Senior opposite the center of the first platoon, the Junior opposite the center of the second platoon; if there be but one officer, he places himself in front of the center of the guard. The Adjutant superintends the formation, returns the salute of the Sergeant-major with the right hand, draws his sword, and commands: 1. *Officers and non-commissioned officers, to the front and center*, 2. MARCH. At the command *march*, the Officers of the Guard advance, closing toward each other, and halt at three yards from the Adjutant; the non-commissioned officers pass by the flanks, and form in the order of rank from right to left, three yards in rear of the officers. The Adjutant then assigns their places in the guard according to rank, as follows: *Senior Officer, Commander of the Guard, and chief of the first platoon; Junior Officer, chief of the second platoon; Senior Sergeant, right guide and guide of the first platoon; Second Sergeant, left guide and guide of the second platoon; the remaining non-commissioned officers as file-closers of the first and second platoons.* The Adjutant then commands: 1. *Officer and non-commissioned officers*, 2. *To your posts*, 3. MARCH. At the command *march*, the Junior Officer of the Guard and the non-commissioned officers take the posts assigned them, the Junior Officer placing himself three yards in front of the center of the second platoon, the non-commissioned officers passing around the flanks. If there be but one Officer of the Guard, the Adjutant commands: 1. *Non-commissioned officers*, 2. *To your posts*, 3. MARCH. The Senior Sergeant takes his post in the line of file-closers opposite the center of the second platoon. The officers and non-commissioned officers having taken their posts, the Adjutant directs the Commander of the Guard, *Inspect your guard, Sir;* at which he faces about, commands, 1. *Order*, 2. ARMS, 3. *Inspection*, 4. ARMS, returns his sword and inspects the guard. During the inspection the band plays. The Adjutant, during the inspection, returns his sword, observes the general condition of the guard, and replaces any man who does not present a creditable appearance by a supernumerary from his company. He also, when so directed, selects, as Orderly for the Commanding Officer, the soldier who is neatest in general appearance, and notifies the Officer of the Guard of his selection. When there are two Officers of the Guard, the Junior may, at the discretion of the Senior, inspect the rear rank. If there be no Officers of the Guard, the Adjutant inspects, and the Sergeants designated as chiefs of platoon place themselves in the line of file-closers, opposite the centers of their platoons. If the guard be too small to be divided into platoons, the Senior Sergeant, who commands the guard, places himself on the right of the front rank, and is covered by the right guide in the rear rank. The inspection ended, the Adjutant places himself about thirty yards in front of and facing the center of the guard, and draws sword; the Officers of the Guard place themselves three yards in front of the centers of their respective platoons, and draw sword; if there be but one, he places himself three yards in front of the center of the guard; at the same time the Officers of the Day take post in front of and facing the guard, about thirty yards or more from the Adjutant, the old Officer of the Day three yards to the right and one yard to the rear of the new Officer of the Day. The Adjutant then commands, 1. *Parade*, 2. REST, 3. SOUND OFF. The band, commencing on the right, plays along the line in front of the Officers of the Guard to the left, and back to its place on the right, when it ceases. The Adjutant now commands: 1. *Guard*, 2. ATTENTION, 3. *Carry*, 4. ARMS, 5. *Close order*, 6. MARCH. At the command *march*, the officers face about, and place themselves two yards in front of their respective platoons. The Adjutant then commands, 1. *Present*, 2. ARMS; faces to the new Officer of the Day, salutes, and reports: *Sir! The guard is formed.* The new Officer of the Day, after acknowledging the salute with the right hand, directs the Adjutant: *March the guard in review, Sir.* If the Adjutant be senior to the Officer of the Day, he reports without saluting; the Officer of the Day then salutes and gives the Adjutant the same directions as before; the Adjutant returns the salute. The Adjutant faces about, brings the guard to a *carry*, and commands: 1. *Platoons right wheel*, 2. MARCH. At the first command, the chiefs of platoon, if not already there, place themselves two yards in front of the centers of their respective platoons. At the command *march*, the platoons wheel to the right on a fixed pivot, as explained in the School of the Company; the band wheels to the right and places itself twelve yards in front of the first platoon. The Adjutant places himself abreast of the first platoon and six yards from its left flank; and the Sergeant-major six yards from the left flank of the second platoon. The Adjutant then commands: 1. *Pass in review*, 2. *Forward*, 3. *Guide right*, 4. MARCH. The guard now passes in quick time past the Officer of the Day, according to the principles of review, the Adjutant, the chiefs of platoon, Sergeant-major and Drum-major saluting. If senior to the Officer of the Day, the Adjutant does not salute. The band, having passed the Officers of the Day, wheels to the left out of the column, and places itself opposite the Officers of the Day, and facing them, ceasing to play when the rear of the column has passed; the trumpeters or field-music detach themselves from the band when the latter wheels out of the column, and remain in front of the guard. The guard having passed the Officers of the Day, the Adjutant and Sergeant-major halt, return their swords and retire. The Commander of the Guard wheels it into line to the left without halting, breaks it into column of fours to the right, places himself on the left of the leading guide, and, preceded by the trumpeters, who begin to play when the band ceases, conducts his guard to its post. The Officers of the Day face toward each other and salute, the old Officer of the Day giving the old or standing orders to the new Officer of the Day. While the band sounds off, and the guard is marching in review, the Officers of the Day stand at parade rest with arms folded. They both come to attention before the guard is to be presented, and as the head of the column approaches. The new Officer of the Day returns the salute of the Drum-major, should there be one, with the right hand, and uncovers while the guard is passing, holding his hat with the right hand over the left shoulder. The First Sergeants and supernumeraries come to *order arms*, *parade rest*, and *attention*, with the guard; they remain at *order arms* while the guard is being presented and wheeled into column. The senior First Sergeant commands, 1. *Parade*, 2. REST, at the command *march* for passing in review, and, 1. *Supernumeraries*, 2. ATTENTION, when the Officers of the Day come to attention. The First Sergeants come to *parade rest*, and to *attention* with the supernumeraries. The rear of the column having passed the Officers of the Day, the senior First Sergeant commands, 1. *Carry*, 2. ARMS, after which each First Sergeant marches his supernumeraries to the company parade and dismisses them. The guard, if too small to be divided into platoons, may be wheeled to the right and passed in review as above; the Commander of the Guard is two yards in front of its center; the Adjutant is six yards from its left flank, the Sergeant-major covers him on a line with the file-closers. The Officer of the Day may direct the Adjutant: *March the guard to its post, Sir.* The Adjutant faces about, brings the guard to a *carry*, and then commands: 1. *Guard to its post*, 2. *Fours right*, 3. MARCH (or, *Double time*, MARCH). At the second command, the Senior Officer places himself facing to the right, two yards in front of the right guide; the Junior Officer places himself in the line of file-closers in rear of the center of the second platoon. At the command *march*, the guard wheels by fours to the right; the trumpeters or field-music place themselves in its front; the Senior Officer takes command and places himself on the left of the leading guide; the Adjutant and Sergeant-major return swords and retire, and the First Sergeants march off their supernumeraries; the Officers of the Day salute each other as before, and the band retires. As the new guard approaches the guard-house, the old guard is formed in line, with the trumpeters or field-music two yards to its right; and, when the trumpeters or field-music of the new guard arrive opposite its left, the Commander of the old guard commands: 1. *Present*, 2. ARMS. The new guard having passed, he commands: 1. *Carry*, 2. ARMS. The new guard marches in quick time past the old guard, arms at a *carry*, officers saluting. The trumpeters having marched three yards beyond the trumpeters or field-music of the old guard, change direction to the right, and, followed by the guard, change direction to the left when on a line with the file-closers of the old guard. The change of direction is without command; the Senior Officer of the Guard halts on the line of the front rank of the old guard, allows his guard to march past him, and, when its rear approaches, wheels it by fours to the left, halts it, establishes the left guide three yards to the right of the trumpeters or field-music of the old guard, and on a line with its front rank, and then dresses his guard to the left; the trumpeters or field-music of the new guard are two yards to the right of its front rank. The new guard being dressed, the Commander of each guard, in front of and facing its center, commands, 1. *Present*, 2. ARMS, resumes his front, and salutes. The officers, having saluted, face their guards, and command: 1. *Carry*, 2. ARMS, 3. *Order*, 4. ARMS. Should the guards be commanded by Sergeants, they present with their guards, standing on the right or left of the front rank, according as they command the old or new guard. If one guard is commanded by an officer, the other by a non-commissioned officer, the latter stands on the flank of his guard and salutes with it. The Officer of the new guard now divides the guard into three reliefs, numbers them *first*, *second*, and *third*, from right to left, and directs a list of the guard to be made; experienced soldiers are placed over the arms of the guard and at the remote and responsible posts; the Officer of the Guard then proceeds to take possession of the guard-house or guard-tent, and the articles and prisoners in charge of the guard. During the time of relieving the sentinels and of calling in the small posts, the two guards stand at place rest, and the old Commander gives to the new all the information and the instructions relating to his post. The first relief having been designated and brought to a carry, its Corporal commands: CALL OFF. Commencing on the right, the men call off alternately front and rear rank: *one*, *two*, *three*, *four*, and so on; the Corporal then commands: 1. *Right*, 2. FACE, 3. *Support* (or, *Right shoulder*), 4. ARMS, 5. *Forward*, 6. MARCH. The Corporal marches on the left, and near the rear file, in order to observe the march. The Corporal of the old guard marches on the right of the leading rank, and takes command when the last one of the old sentinels is relieved, changing places with the Corporal of the new guard. When the relief arrives at fifteen yards from a sentinel, he halts and faces to it, with arms at a carry. At six yards from him the Corporal commands: 1. *Relief*, 2. HALT. The Corporal then adds, according to the number of the post: 1. *No.* (——), 2. *Arms*, 3. PORT. At the third command the two sentinels come to *arms port*, and approach each other. The old sentinel, under the supervision of both Corporals, whispers his instructions to the new sentinel; both then come to a *carry*. The Corporal then commands: 1. *Support* (or, *Right shoulder*), 2. ARMS, 3. *Forward*, 4. MARCH. As the relief passes, the old sentinel takes his place in its rear at a support (or right shoulder) arms; the other sentinels are relieved in a similar manner. The sentinel at the guard-house is the first relieved, and is left behind. The detachments and sentinels of the old guard, having come in, form on its left, and both guards are brought to a carry; the Senior Officer of the old guard then marches it, with the guide right, six yards to the front, when he commands: 1. *Fours right*, 2. MARCH. At the command *march*, the guard wheels by fours to the right, the trumpeters or field-music begin to play, and the guard marches in quick time past the new guard, which stands at *present arms*, officers of both guards saluting. The Commander of the new guard, if an officer, stands two yards in front of its center while the old guard is passing; if a non-commissioned officer, he stands on the right of the front rank. The new guard is brought to a carry as soon as the old guard has passed, and, when the latter has marched about fifty yards from the post of the guard, the Commander of the new guard orders his men to stack arms, or to place them in the gun-racks. The Commander of the Guard then makes himself acquainted with all the instructions for his post, visits the sentinels, and questions them and the non-commissioned officers relative to the instructions they have received from the old guard. On arriving on the regimental or garrison parade, the Officer of the old guard forms it in line and halts it, orders the company details composing it two yards to the front, and sends them, under charge of non-commissioned officers or privates, to their respective companies. Before the men are dismissed, the cartridges are drawn, or discharged at a target. When the details return to their companies, the chiefs of squad examine the arms and accouterments of their men, and cause them to be put away in good order. The Officers of the Day visit and inspect the guard-house, or tents, while the old guard is being relieved, verify the number of prisoners, and then proceed to the office or presence of the Commanding Officer, who receives the report of the old Officer of the Day, relieves him, and delivers his instructions to the new Officer of the Day. In visiting the guard-house the Officers of the Day will each be saluted by his own guard, its Officer commanding: 1. *Present*, 2. ARMS. When other officers entitled to a salute approach, the Senior Officer of the two guards commands: 1. *Old and new guards*, 2. *Present*, 3. ARMS. In rendering honors, the Commander of the Guard, if an officer, stands in front of its center, faces about to command *present arms*, resumes his front, and then salutes; he also faces about before commanding *carry arms*, and again resumes his front. If a non-commissioned officer commands the guard, he presents and carries arms with it, standing on the right of the front rank. When a small detachment is mounted for guard, as at a one-company post, the officer mounting it brings the detachment to rear open order, and, after having inspected it, places himself in front of and facing it, and commands: 1. *Parade*, 2. REST, 3. SOUND OFF. The trumpeters or field-music sound off, standing on the right, after which the guard is brought to close order, and without presenting (unless there be an Officer of the Day) is marched direct to its post by the commands: 1. *Guard to its post*, 2. *Right*, 3. FACE, 4. *Forward*, 5. MARCH. The non-commissioned officer commanding the guard during the mounting stands on the right of the front rank. In conducting the guard to its post he marches near its left and rear, where he can see its movements. A file-closer, if there be one, takes his place as guide. The same honors are rendered at the guard-house as already explained. If the guard be armed with the saber, the commands at guard-mounting are modified to meet the requirements of the arm used.

Mounted guard-mounting is conducted in single rank on the same principles as guard-mounting dismounted, with the following modifications: No supernumeraries are formed with the guard; the First Sergeant inspects the dress and general appearance of his detail before causing it to mount. The sabers of the First Sergeants are drawn; the sabers of the details are in the scabbard. The officers and non-commissioned officers take the distance of six yards from the rank when at open order, and one yard when at close order; the First Sergeants, in reporting, salute with the saber, and then place themselves six yards in rear of the non-commissioned officers of the guard. The assignment of officers and non-commissioned officers is omitted, the non-commissioned officers remaining in the position above prescribed; the guide of each platoon is the file on the flank toward which the guide is announced. If any man does not present a creditable appearance, the Captain is notified through the First Sergeant, and sends a man to the Officer of the Guard, at the guard-house, to replace him. If there be no Officer of the Guard, the Adjutant, when inspecting, notifies the senior two non-commissioned officers to serve as chiefs of platoon; or, if the division of platoons be omitted, he notifies the senior non-commissioned officer to command the guard; the non-commissioned officer places himself on the right of the rank. The Adjutant omits the commands *parade rest* and *guard attention*, and, to present the guard, commands: 1. *Draw*, 2. SABER, 3. *Present*, 4. SABER. The platoons wheel to the right. The Officers of the Day do not fold their arms, and the First Sergeants, having taken their posts, remain at attention till the rear of the guard has passed the Officers of the Day, when they return their sabers and immediately retire. See *Grand Guard-mounting* and *Undress Guard-mounting*.

GUARD OF HONOR.—The guard drawn up to receive royal personages and persons of distinction, and to attend at state ceremonials. It consists, as a general rule, of 100 rank and file, with a Captain in command, two subaltern officers (one carrying the first color), and a proportion of Sergeants. The regimental band attends when the Queen or other exalted person is to be received.

GUARD-REPORT.—The report which the Officer or Non-commissioned Officer in Charge of a Guard sends in to headquarters on dismounting. The report of his tour of service always includes the outposts. The following is the form of the report:

Report of a Guard mounted at ——, on the——, and relieved on the ——.

	Lieutenants.	Sergeants.	Corporals.	Musicians.	Privates.	Total.	Aggregate.	Articles in charge.				Received the foregoing. A. B., —— ——, *Officer of the Guard.*

Commanding the Guard.

GUARD-ROOM.—The room occupied by the guard during its tour of duty. There is a room in the guard-house in which prisoners awaiting the investigation of their crimes are kept. Under the same roof a room is attached in which the Officer Commanding the Guard resides during his tour of duty.

GUARDS.—The élite of the troops in all armies, and usually those most heavily armed. In the British service, the Guards constitute, in time of peace, the garrison of London, and the guard of the Sovereign at Windsor. The Guards compose what is called the Household Brigade, and include in cavalry the 1st and 2d Life-guards, and the Royal Horse-guards (blue), and in infantry the Grenadier Guards, the Coldstream Guards, and the Scots Fusilier Guards. These distinguished corps comprise 1302 cavalry in three regiments, and 5940 infantry in seven battalions. Before the abolition of purchase, the officers of the regiments

Royal Horse-guardsman (1742).

of Foot-guards held higher army rank than that they bore regimentally; that is, Ensigns ranked with Lieutenants of other regiments, Lieutenants with Captains, Captains with Lieutenant-colonels; and on exchanging into the Line, they were thus enabled to exchange into the higher positions, a circumstance which often placed officers of comparatively short service over veterans of the Line, and caused, perhaps, more heart-burning than any other anomaly among the regulations. When purchase was the rule, every officer in the Guards was quite ready to accede to it; when it was abolished in 1871, this exceptional rank was also abolished in regard to all officers newly entering the Guards.

GUARD-SHIP.—The ship of war in charge of a port. She generally acts also as a depot for seamen raised there until appropriated to other vessels, and her Captain is responsible for the safety and proper preservation of the men-of-war which may be laid up—out of commission—in the harbor. The Superintendent of a dock-yard, if a Flag-officer, carries his flag at the mast-head of the guard-ship; if he be only a Captain, the guard-ship is usually under his nominal command, although the actual duties are carried on by the Commander or next Senior Officer.

GUARD'S INSTITUTE.—An establishment in London which consists of reading-rooms, lecture-rooms, etc., for all officers and soldiers in the metropolis. It was inaugurated by the Duke of Cambridge, July 11, 1867.

GUARDS OF THE TRENCHES.—In a siege-operation, to protect the workmen from sorties, as many battalions of the line as may be requisite, termed the *Guards of the Trenches*, are thrown forward about thirty paces in advance of and on the flanks of the men who open the first parallel. The flank companies of these battalions, divided into sections, cover the front of the battalions, and are posted about thirty paces from them; and each section posts two sentinels at about the same distance to its front. The sentinels keep a lookout, kneeling on one knee; the remainder of the troops lie flat on the ground to avoid the fire of the defenses. When the working-parties are all posted, the men of each lying flat until all are ready to commence the work, the order is given to rise, ground their arms a few paces to the rear, and break ground. The guards of the trenches keep their position until near dawn, when they are withdrawn and take post in the parallel, which, by this time, is nearly excavated to its full width.

GUARD-TENTS.—The tents occupied by the guard, when a command is in the field or camp.

GUASTADOURS. — Turkish Pioneers. Armenians and Greeks are generally employed in the Turkish armies to do the fatigue-work that is necessary for the formation of a camp, or for conducting a siege.

GUDDA.—The Indian term for a fool; also a small fort erected upon a hill or eminence.

GUDDEELAH.—Indian name for a padded cloth placed on the back of a draught-elephant before the harness is put on. It is made of kurwah cloth stuffed with cotton, the edges being bound with leather.

GUDGEON.—The circular part of a shaft or axle upon which a wheel revolves. The gudgeons on cast-iron axles are simply parts of the extremities of the axles turned exactly circular in a lathe. The circular apertures in which the gudgeons turn are called *brasses;* they are made of a composition of copper and tin, and are very durable, as well as not readily worn by the friction of the iron axles. The beams in which the brasses are fixed are called "bearings."

GUELPHIC ORDER.—An Order of Knighthood for Hanover, instituted by George IV. when Prince Regent, on August 12, 1815. It is both a military and civil order, unlimited in number, and consisted originally of three classes—Knights Grand Cross, Commanders, and Knights—to which the Revised Statutes of 1841 have added another class of simple members. The Grand-Mastership is vested in the Crown of Hanover. The badge of the Order is a gold cross surmounted by the Hanoverian Crown—between each division of the cross is a lion passant gardant. In the center is the horse courant of Hanover, surrounded by a blue circle, and the motto, *Nec aspera terrent.*

GUELPHS AND GHIBELLINES. — The names of two great parties, the conflict of which may almost be said to make up the history of Italy and Germany from the eleventh till the fourteenth century. The origin of these names was formerly the subject of much speculation; but antiquarians are now agreed in tracing them respectively to the two families, Waiblingen and Welf, which in the twelfth century were at the head of two rival parties in the German Empire, and whose feuds came to be identified historically with the respective principles for which these parties contended. The actual origin of the assumption of the names is commonly fixed at the great battle of Weinsberg, in Swabia, 1140 A.D., in which the two rival claimants for the Empire, Conrad of Hohenstaufen, Duke of Franconia, and Henry the Lion, of the House of Welf, Duke of Saxony, rallied their followers by the respective war-cries, "Hie Waiblingen!" "Hie Welf!" but it is certain that the names were in use from an earlier date, although, probably, rather as representing the family feud than the political principles which the two families afterwards severally supported. As the chief theater of the conflict of these parties was Italy, the original names took the Italian form of *Ghibellini* and *Guelfi*. The former may, in general, be described as the supporters of the imperial authority in Italy, the latter, as the opponents of the Emperors; and as the opposition to imperial authority in Italy arose from two distinct parties, which, for the most part, made common cause with each other—from the Church, which asserted its own spiritual independence, and from the minor principalities and free cities, which maintained their provincial or municipal rights and liberties—the history of the struggle is involved in much confusion, and is variously related, and its merits variously appreciated, according to the point of view from which it is regarded. To the churchman, it is the struggle of the Church against the State; to the friend of popular principles, it is the conflict of liberty against absolutism and centralization. The same individual—as, for example, the poet Dante—is found to change sides in the struggle. For the most part, however, the interests of the Church in these mediæval contests, although regarded by Protestants as excessive in degree, must be confessed to have fallen in with the claims of political and personal freedom. Five great crises in the strife of the Guelph and Ghibelline parties are commonly noted by historians: under Henry IV., in 1055; under Henry the Proud, in 1127; under Henry the Lion, in 1140; under Frederick Barbarossa, in 1159; and in the pontificate of the great champion of churchmanship, Innocent III. The cities of northern Italy were divided between the two parties—Florence, Bologna, Milan, and other cities, as a general rule, taking the side of the Guelphs; while Pisa, Verona, and Arezzo were Ghibelline. The great Italian families, in like manner, took opposite sides; but the policy of each family frequently varied from one generation to another. In general it may be said that the nobles of the more northern Provinces of Italy inclined to the Ghibelline side, while those of the central and southern Provinces were Guelph. By degrees, however, especially after the downfall of the preponderance of the German Emperors in Italy, the contest ceased to be a strife of principles, and degenerated into a mere struggle of rival factions, availing themselves of the prestige of ancient names and traditional or hereditary prejudices. Even in 1272 Gregory X. could with truth reproach the Italians with their sanguinary animosities for the sake of what were but names, the meaning of which few of them could understand or explain; and in the following century, in 1334, Benedict XII. practically disallows altogether the reality of the grounds of division between the parties, by prescribing, under pain of the censures of the Church, the further use of those once-stirring names which had long been the rallying-words of a sanguinary warfare.

GUERITE.—A small loop-holed turret in the wall of a fortress, from which a sentry may command a view and fire over the ditch. Guerites are generally fixed to the acute points of bastions.

GUERRE.—War; warfare; art of war; dissension; strife. *En guerre*, at war; in action; ready for action; any piece of ordnance unlimbered, trunnions shifted, and everything made ready for firing.

GUERRILLAS.—The name given in Spain to the armed bands, composed of peasants and shepherds, who, on occasion of foreign invasion or civil wars, carry on an irregular warfare on their own account. From 1808 to 1814 they were regularly organized against the French, and, being favored by the charac ter of the country, were successful on various occasions, especially at the commencement of the war, under Empecinado, the Pastor Merino, Mina, and other leaders. The country itself suffered from the Guerrillas, who revenged political treachery, or even the barest suspicion of it, by fearful devastations. Many of them, and particularly Mina's band, joined Wellington, and after having undergone a course of discipline, rendered signal service as regular troops. In all the recent civil wars of Spain, the Guerrillas, especially those of the Basque Provinces, acted a prominent part on the Carlist side.

When Guerrillas are taken captive, they should be treated according to the usual customs of war. In the Franco-German War, the Germans refused to recognize as soldiers, or extend the privileges of war, to the *Francs-Tireurs*—a body of French volunteer sharp-shooters who, to a great extent, adopted this system of guerrilla warfare. See *Partisan*.

GUERRILLERO.—An irregular soldier; a member of a guerrilla band or party. See *Guerrillas*.

GUET.—A term attached to those persons belonging to the French body-guard who did duty during the night. It also signified rounds, or those duties of a soldier, or patrolling-party, which are prescribed for the security of a town, etc., and to prevent surprises. It is also taken in a military sense in conjunction with other words; as, *guet à pied*, foot-patrol; *guet à cheval*, horse-patrol, etc.

GUEUX.—The name assumed by the confederated nobles and other malcontents who opposed the tyrannical policy of Philip II. of Spain in the Low Countries. Philip having sent nine Inquisitors to that country to put into execution the decrees of the Council of Trent, provoked by this act the bitter resentment of the Protestants, as well as of the Catholics and nobility, who saw in it an attempt to curtail their ancient liberties. A party of opposition was thus formed, and, headed by Counts Louis of Nassau and Henry de Brederode, declared in an Act called the "Compromise," which was remitted to the Regent Margaret, their fixed determination to ignore utterly the authority of the Inquisitors. On the admission of a deputation from them to an audience, the Regent seemed somewhat unnerved by their bold front, and inclined to yield to their demands; when one of her Council approached her, and whispered that she "need not be afraid of these gatherings of beggars." The remark having been overheard by some of the deputation, the abusive epithet was assumed as the title of their Association. As the sign of fraternity, each of the "Beggars" wore a medal known as the "Beggar's Denier," formed of gold or silver, and stamped on the obverse with the image of Philip II., and the inscription, "In everything faithful to the King;" and on the reverse with a wallet, such as the mendicant monks carried, held in two hands, with the words, "Even to carrying of the wallet." The "Beggars" maintained a long and vigorous contest against the despotic proceedings of Philip and his advisers, but were ultimately compelled to succumb to superior force. A branch of them, "The Beggars of the Sea," under the bold leadership of the savage Count de la Marck, were almost uniformly successful in their enterprises: they several times defeated the Spanish fleet, captured transports with supplies for Alva's army, captured several fortresses, and succored besieged places along the coast.

GUICHETS.—Small doors or outlets which are made in the gates of fortified towns. They are generally four feet high, and two broad, so that a man must stoop to get through. In garrison towns the guichet is usually left open for the space of one quarter of an hour after retreat, in order to give the inhabitants time to enter.

GUIDES.—1. The non-commissioned officers, and other enlisted men, who take positions to mark the pivots, marches, formations, and alignments in modern discipline. The French call them *jaloneurs*. Guides and file-closers always execute *order arms*, *fix* and *unfix bayonets*, and *carry arms*. In rendering honors they execute the *present*, *reverse*, and *rest on arms*. On drill they execute the *support* and *right shoulder arms*, except the guide of each subdivision in column when marching in common or quick time, and the guides who mark the line of battle during its formation. They execute the other movements of the manual only when specially directed.

2. In military affairs, guides are usually persons drawn from the country in which an army is encamped. A sufficient body of intelligent men is collected at headquarters to enable one or more to be sent with every detachment of troops which leaves the camp. A guide should be quick of eye, experienced in the topography of the country, and, above all, faithful. As, however, guides must on most occasions be drawn from the midst of a hostile population, and have probably only a pecuniary interest in serving well, their conduct is always watched with the utmost jealousy, death being awarded as the punishment for the least departure from trustworthiness. Any treason or incompetence on the part of a guide might involve the most disastrous consequences to a whole expedition. In the French army a considerable corps of cavalry and infantry bear the name, but the name only, of "guides." They were first formed in 1744, as a small company of messengers on active service. The number was gradually increased until the time of Napoleon I., who formed them into a guard 10,000 strong.

Trustworthy guides are invaluable, but most rare, in an enemy's country. The best, from the information they acquire by their habits of life, are to be found among those classes whose avocations keep them much abroad, going from place to place within a certain sphere constantly; such as common carriers, hunters, smugglers, etc. Among the first things to be attended to by an officer, in taking post at any point, is to find out persons of this class, and to ascertain their whereabouts when wanted. Kind treatment, *douceurs*, and promises should not be spared, to enlist either their good-will or their interests; and, if policy requires it, they may openly be treated with apparent harshness, to screen them from odium among their neighbors. If none of this class can be found, then resort must be had to a higher; local authorities being in preference selected, and if necessary forced to act. Here very careful treatment is requisite; when the necessity of the case is admitted by them, much may be gleaned by kindness, courtesy, and a certain deference, from such persons, that cannot be looked for from their inferiors. Before starting on his mission, the officer should question his guide thoroughly; and if he has several, question each apart; like precautions should be taken with respect to other inhabitants. Care must be had to find out the usual beats of one taken as a guide, so as not to take him out of his own neighborhood. In all cases, the guide must be well watched, however trustworthy he may seem. If unwilling or sulky, he must, if needs be, be tied, and attached to a strong man, with a rope around his middle; being first strictly searched for any cutting instrument about him. Should there be but one guide, he must necessarily be placed with the most advanced portion of the detachment accompanying the officer. If there are several, one must be there also; the one apparently the most intelligent with the officer, who should ply him with questions; and the others in the rear, strictly guarded. It may be well to remark that guides are useful even in a country of easy communications; as, in case of a rencontre, they may point out byways convenient for retreat, if necessary.

3. In the Indian army the name of "guides" is given to a regiment of cavalry and infantry attached to the Punjab frontier force. It was raised by the late Sir Henry Lawrence, chiefly with the view to the men acting as scouts, and obtaining every available information about the country they happened to be in; also to act in expeditions as *avant-couriers*

of the force to which they belonged, and (the cavalry branch) in carrying orders that required dispatch.

GUIDON.—1. One who carries a flag. Also, one of a community of guides established at Rome by Charlemagne to accompany the pilgrims to the Holy Land.

2. A small flag or streamer usually carried by the mounted troops. It is broad at the one end and is nearly pointed at the other. It is sometimes used to direct the movements of infantry, and to make signals at sea.

In the United States army, each company of the mounted troops has a silken guidon, and the names of battles in which companies or batteries in the service of the United States have borne a meritorious part are inscribed upon their guidons. Within the spirit of this regulation, battles are important engagements between independent armies in their own theaters of war, in contradistinction to conflicts in which but a small portion of the opposing forces are actually engaged—the latter being called, according to their nature, "affairs," "combats," skirmishes," etc. A battle has for its object the determination of important questions of policy or strategy; an engagement may be partial, and yet, if it tend to these ends, it is also entitled to the dignity of being termed a battle. The portion of a regiment which must be engaged in a battle to entitle the regiment to have inscribed upon its colors the name of the battle is that number of companies which by tactics and the regulations is entitled as a battalion, habitually, to carry the colors of the regiment. The inscriptions on the guidons of artillery batteries do not include the honors to which the regiment is entitled, but those won separately by detached mounted batteries.

The guidons for cavalry are made of silk, with stars and stripes like the national flag; made swallow-tailed. Stars gilt, one and one eighth inches in diameter from point to point. The guidon measures from the lance three feet five inches to the end, and fifteen inches to the fork of swallow-tail, and two feet three inches on the lance. The fork of the swallow-tail is equidistant from the top and bottom of guidon. The letter of the company is embroidered in yellow silk, or painted on one of the white bars of the flag. The lance is one and one fourth inches in diameter, and nine feet long, including spear and ferrule.

When mounted, the heel of the staff rests in the socket attached to the right stirrup; the right hand grasps the staff at the height of the elbow. The guidon salutes as follows: (*First motion:*) Lower the staff by straightening the arm to its full extent. (*Second motion:*) Bring back the staff to the habitual position. Dismounted, the heel of the staff is supported at the right hip, and, in saluting, the guidon, in the first motion, slips the right hand along the staff to the height of the eye before lowering the staff.

GUIGE.—A belt of the Middle Ages, by which the shield was secured to the person of the wearer, and also carried by him without inconvenience, suspended about his neck.

GUILLOTINE.—The instrument of decapitation introduced during the French Revolution by the Convention, and named after its supposed inventor, Josephe Ignace Guillotin, a Physician, who, however, it is ascertained, was only the person who first proposed its adoption. It is composed of two upright posts, grooved on the inside, and connected at the top by a cross-beam. In these grooves, a sharp iron blade, placed obliquely, descends by its own weight on the neck of the victim, who is bound to a board laid below. The speed and certainty with which this machine separates the head from the trunk gives it a great superiority over the axe or sword. The invention of machines of this kind is ascribed to the Persians. In Italy, from the thirteenth century, it was the privilege of the nobles to be put to death by a machine of this kind, which was called *mannaia.* Conradin of Swabia was executed by such a machine at Naples, in 1268. An instrument resembling the guillotine was likewise employed in Germany during the Middle Ages. During the sixteenth and till late in the seventeenth century, a machine called the *maiden*, which differed but slightly from the guillotine, was employed in Scotland for the purpose of decapitation. That such an apparatus was known and used in France at an earlier period is proved by the execution of the Duc de Montmorency, who is described as having been executed by a falling axe at Toulouse, in 1632. The Dutch, too, in the eighteenth century employed a decapitating machine in executing slaves in their Colonies.

GUILTY.—The form of verdict given by a Jury or Court in criminal cases when the crime charged has been found proved. In England, there are only two verdicts which can be given in such cases, viz., Guilty or Not Guilty; but in Scotland there is an intermediate verdict, called "Not Proven," which, though in reality a verdict of Not Guilty (and it is so entered in England), yet is allowed to be given by Juries when they are not satisfied that sufficient legal evidence has been given, but nevertheless consider there was some foundation for the charge, or at least some ground for suspicion. It has been objected to this verdict that it leaves a stigma on the party; nevertheless it is firmly adopted in the law and practice of Scotland.

GUISARME.—A lance having a small axe fixed at the foot of its blade or lance-head on one side and a spike projecting on the other side. It was popular in the sixteenth century. See *Gisarme.*

GUISARMIERS.—French foot-soldiers (piétons) of the free archers, armed with the *guisarme.*

GULES.—The term by which the color red is known in Heraldry. In engraving it is marked by perpendicular lines traced from the top of the shield to the bottom. It is supposed to indicate valor, magnanimity, and the like, and is regarded as the most honorable heraldic color. See *Heraldry.*

GUN.—A term applied in its most general application to fire-arms of any description, but in the more restricted and technical sense to cannon. A gun is a frustum of a right cone, with a cylinder excavated round the axis, to serve as a bore. Close home to the end of this cylinder the powder is driven, and outside it is the ball to be expelled. The trunnions are cast in one mass with the piece, and are placed in the second reinforce in such a position that the breech-end of the gun outweighs the muzzle. Their axis is generally about half their diameter below the axis of the piece. This locality has several conveniences; but for the maximum of steadiness in the recoil, it has been shown that the axes of the trunnions and of the gun should exactly intersect. The use of the trunnions is to suspend the cannon on its carriage in such a manner that it may be readily depressed or elevated, but so that it shall have no horizontal motion which is not shared by the whole carriage. The vent or touch-hole, the channel through which the charge is fired, is a small cylindrical orifice leading at an angle from the breech of the bore towards the base-ring. The explosion within reacts with great force on the lower portion of the vent, and in case of rapid or long-continued firing soon honeycombs the iron or brass, often dislodging considerable fragments. This, besides diminishing the regularity of the action of the powder upon the projectile, would involve danger of bursting if permitted to any great extent. The gun so affected is therefore *bouched*, that is, has a new vent constructed. This process consists of drilling a female screw, of larger than the required diameter, in the metal of the gun. Into this matrix a bar of pure copper is screwed (copper being the metal least liable to fuse under the intense heat of ignited gunpowder), and the vent is then drilled through the copper. Sir A. Dickson devised the following simple mode: he rammed a cartridge of sand firmly into the breech, then filled the vent and all the interstices with molten copper, and had only to bore a hole through the latter to complete the operation. In cases of great urgency, even this simple procedure may be

shortened by the insertion of the stem of a tobacco-pipe during the filling; the pipe, on being removed, leaves a perfect vent. A gun is suited to fire hollow as well as solid projectiles; and the only limit to the charge is the strength of the projectile to resist rupture in the piece. The employment of shells in the heavy cannon, after the manner of solid shot, constitutes the basis of what is known as General Paixhan's System of Artillery, and not the peculiar form of the gun, as is generally supposed. The caliber of a gun is generally expressed in terms of the weight of a solid cast-iron ball of the size of the bore. See *Cannon*, *Ordnance*, and *Small-arms*.

GUN-BARREL.—The iron for all good musket-barrels contains a portion of steel, or undergoes some kind of steeling process. Horseshoe-nails or stubs, after much violent usage, yield a very tough kind of iron when reheated; and English gun-makers have been accustomed to buy such refuse on the Continent. The best barrels are now made of laminated, twisted, and Damascus steel. To prepare *laminated steel*, Mr. Greener, a celebrated Birmingham gunsmith, collects scraps of saws, steel pens, files, springs, and steel tools from the various workshops; cuts them into small and nearly equal pieces; cleans and polishes them by revolving in a cylinder; fuses them into a semi-fluid state; gathers them into a "bloom" or mass; forges this bloom with a three-ton hammer; hardens and solidifies it with a tilt-hammer; rolls it into rods; cuts each rod into pieces six inches long; welds these pieces together; repeats the rolling, cutting, and welding several times; and thus finally brings the metal into a very hard, tough, fibrous, and uniform state. *Twisted steel* for barrels is made by taking thin plates of iron and steel, laying them alternately one on another in a pile, welding them by heat and hammering, and twisting them by very powerful mechanical agency, until there are twelve or fourteen complete turns to an inch; the length becomes reduced one half and the thickness doubled by this twisting. *Damascus steel* barrels are made of steel which has undergone a still further series of welding and twisting operations. *Stub Damascus* barrels are made of a mixture of old files with old horseshoe-nails; the files are heated, cooled in water, broken with hammers, and pounded in a mortar into small fragments; three parts of these fragments are mixed with five of stub; and the mixture is fused, forged, rolled, and twisted. An inferior kind of Damascus twist is made by interlaying scraps of sheet-iron with charcoal, and producing an appearance of twist, but without the proper qualities. *Threepenny-skelp* and *twopenny-skelp* are inferior kinds of barrel-iron; and the worst of all is *sham-dam skelp*, of which gun-barrels are made for hawking at a cheap price at country-fairs, and for barter with the natives in Africa and the backwoods and prairies of America. The gun-barrel manufacture of England is now almost wholly conducted at Birmingham and at Enfield, very few barrels being made elsewhere. The best barrels are all twisted into form. The skelps, or long strips of prepared steel, are twisted into a close spiral a few inches long; several of these spirals are welded end to end; and the fissures are closed up by heating and hammering. The rough barrel, with a core or mandrel temporarily thrust in it, is placed in a groove, and hammered cold until the metal becomes very dense, close, strong, and elastic. The interior is then bored truly cylindrical by a nicely-adjusted rotating cutting-tool. If, on narrow inspection, the interior is found to be straight and regular, the exterior is then ground on a rapidly revolving stone, and finally turned in a lathe. Commoner barrels are not twisted: the skelps are heated, laid in a semi-cylindrical groove, hammered till they assume the form of that groove, placed two and two together, and heated and hammered until one barrel is made from the two halves. Common barrels are browned externally with some kind of chemical stain; but the best are rubbed with fine files, and polished with steel burnishers.

Comparatively few realize the amount of labor and expense required to manufacture shotgun-barrels that have a fancy figure, and the component parts of which are iron and steel. These barrels must be light, therefore thin, and yet sufficiently strong—conditions which can only be obtained by an extraordinary tenacity of the material. In these combinations this tenacity is secured by mixing and blending the iron and steel so intimately together that the peculiar proportions of each, toughness and elasticity, are imparted to every portion of the mass, and the barrel thus receives the degree of hardness and softness required. The barrels of the celebrated Parker gun are manufactured in the following manner: The iron and steel are placed in layers according to the figure that may be desired, which operation is called *piling*. These layers are securely welded together into a compact bar, as shown in Fig. 1, which must be absolute-

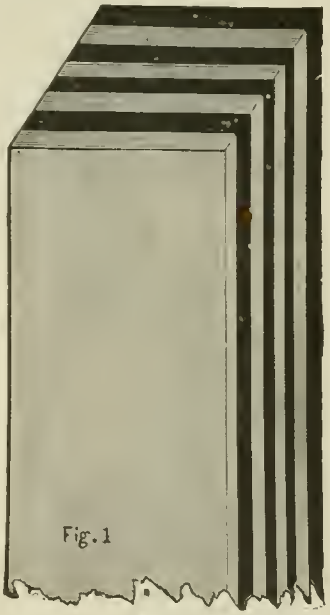

Fig. 1.

ly sound and perfect in every weld, as the slightest spot left unwelded or unsound in this operation will be sure to cause a total loss of the barrel. The process now consists in reducing this bar to such a sized rod as may be required for a certain weight of barrel. This rod is now twisted similar to a rope, as shown at E in Fig. 2, care being taken to have the twist uniform and even. Several of these twisted rods are now placed side by side, being careful to have the inclination of the twist arranged in opposite directions, as shown in the illustration. These several rods are welded together with the same care and precision as in the previous operation, to insure perfectly sound barrels. This is now termed a ribbon and is coiled spirally around a mandrel, as shown at F in Fig. 2. This spiral ribbon is raised to a welding heat and jumped by striking the end against the anvil, thereby welding the edges firmly together. They are then placed upon a welding-mandrel, reheated, and welded from end to end. Much skill and care are required in this operation to reduce the outside diameter to correct size and at the same time preserve the caliber, and also maintain the proper taper, the barrel being much larger at the breech than at the muzzle. The fine figure that appears in the figured barrel is dependent upon the correctness of this and the previous welding operations, for if hammered unevenly, the figure itself will be correspondingly uneven. Then follows the process of hammering in nearly a cold state, whereby the texture of the metal is condensed, closing its pores and making it harder. This finishes the operation of barrel-forging, and the barrel is now ready to be bored, turned, and finished upon lathes manufactured expressly for the purpose. The curly figure that appears in the Damascus, Bernard, and laminated barrels, as shown at G in Fig. 2, is obtained by twisting the rods before referred to, as appears in the illustration at E in Fig. 2, the variation of figure being ob-

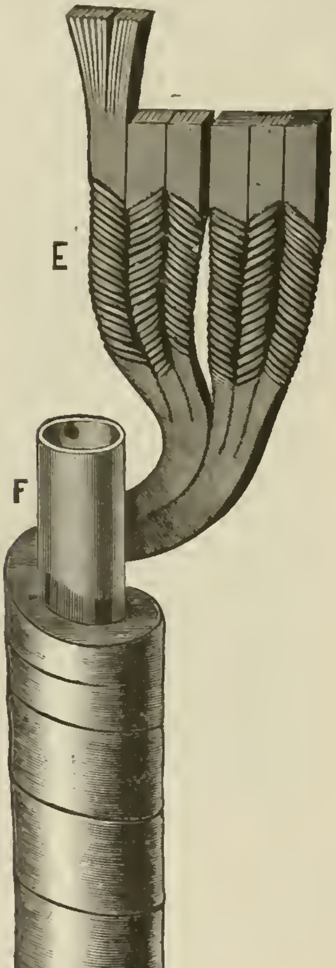

FIG. 2.

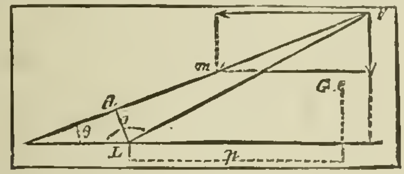
tained by varying the piling. The white marks that appear in the finished barrel are iron, and the dark ones the steel. The fine figure that is on the barrels of the high-priced guns is obtained by an increased number of pieces in the operation of piling. This larger number of pieces necessarily renders the operation of securing perfect welding much more difficult, and the liability of loss is greater. Some imagine that the curly figures of the barrels are simply etched on the outside, when they are, in fact, the visible proof of a superior strength both desirable and important to every shooter who cares for his personal safety; for if an iron barrel, no matter how strong and thick, is defective and does not stand the test, the defective part will splinter into more or less small pieces, while the Damascus, Bernard, and laminated barrels will tear like a woven fabric. This proves clearly the extraordinary tenacity of the material. These fine barrels are not, therefore, worked and twisted so neatly and nicely that they may look beautiful alone, but rather for the reason that greatest lightness, combined with greatest durability, may be produced.

Each barrel, after manufacture, should be carefully tested and submitted to the necessary proof. The diameter of the bore should be verified with the standard and limit gauges. The standard gauge is a cylinder of the diameter of the bore, and the limit gauge is .0025 inch greater. The former should pass freely through the bore, and the latter should not enter it. The barrel should enter the groove of the stock, one half of its diameter, and it should bear uniformly throughout, particularly at the breech. The *vent* should be accurate in its dimension, position, and direction, and a wire should be passed through it, to see that it is free. The *cone* should be sound. The shoulders of the *breech-screw* should fit closely to the end of the barrel, and it should be free from cracks or flaws about the tang screw hole. The *straightness* of the barrel may be ascertained by turning out the breech-screw, and holding the barrel up to the light, and reflecting the image of a straight-edge from the surface of the bore. If the barrel be straight, the reflected image will be straight in all positions of the barrel. The bore must be free from all hammer-marks, ring-bores, cinder-holes, flaws, cracks, etc., as such irregularities cause an inaccuracy of fire. See *Barrel*.

GUN-BOAT.—A small boat or vessel armed with one or more guns of heavy caliber. From its small dimensions, it is capable of running close inshore or up rivers, and from the same cause it has little chance of being hit by a larger vessel at the long range which the carrying power of its guns enables it to maintain. On the outbreak of the Russian War (1854–56), as the British Navy was without a single gun-boat, a large squadron of them was hastily constructed in 1855 and 1856, but too late for that special war. From the haste with which they were put together, most of those vessels proved defective. Their tonnage was small; and their armament usually consisted of one 8-inch gun and one 100-pounder Armstrong gun. In the last two wars with China, gun-boats performed excellent service, having penetrated nearly to Peking, and far up the Yang-tze-kiang. Gun-boats in their more modern form are small mastless vessels mounting one large gun in the bow, and propelled by an engine with single or twin screws. The gun is pointed by means of the helm or the screws, and the gun-boat is in fact a floating gun-carriage. The *Staunch*, the first gun-boat built on this principle for the English navy, has given her name to the whole class. These gun-boats usually carry an armor-piercing gun of 18 tons, on a draught of only 4 feet. But they have been designed to carry even 35-ton guns. Four have lately been built by the Messrs. Armstrong for the Chinese navy—the *Alpha*, *Beta*, *Gamma*, and *Delta;* two of these carry a 25-ton gun, and two a gun of over 30 tons. A small flotilla of such gun-boats, protected only by their small size, would be in coast-defense formidable opponents even for ironclads. At the beginning of the century the United States had over 250 of these vessels; but the "gun-boat system" was soon abandoned. Some of the Continental Navies are well provided with gun-boats.

GUN-CARRIAGES.—Gun-carriages are designed to transport cannon from one point to another, and to support them when fired. A suitable gun-carriage, therefore, should allow the piece to be easily and promptly pointed in the direction of its object; it should be capable of being served by the smallest number of men, and transported with the greatest ease; its recoil, under fire, should be restrained within suitable limits; and it should have sufficient strength and stability to resist overturn or injury from the greatest service-charge. The injury to the carriage arising from the recoil of the piece increases with the square of the velocity of the recoil, which is dependent on the relation between the weight of the carriage and the weight of the piece. Generally speaking, the piece should be heavier than the carriage. Artillery-carriages, like the cannon which they support, are classified into *field*, *mountain*, *prairie*, *siege*, and *sea-coast* carriages. The sea-coast carriages, not being required for the transportation of their pieces, differ materially from the others in their construction.

In every case the carriage must be so constructed as to effectually meet the forces to act upon it. As the axis of the bore intersects the axis of the trunnions, the entire force of the charge, acting on the bottom of the bore, is communicated to the carriage at the trunnion-beds. The carriage being constructed symmetrically with regard to the axis of the piece, we are at liberty, in the following discussion, to suppose that the wheels, trunnion-beds, and trail are all situated in the same plane, and that the resultant of the force of the charge is applied at the point where the axis of the trunnions pierces this plane. The action of the force of the charge is to move the carriage along the surface of the ground (supposed to be horizontal), to press the wheels and trail upon the ground, and to rotate the carriage around the point of contact of the trail with the ground. Let v be the



position of the axis of the trunnions, and mv represent the amount and direction of the force of the recoil, and θ the angle of fire. Let L be the point of contact of the trail and ground, a the distance of this point from the trunnions, α the angle which the line joining these two points makes with the horizontal, G the position of the centre of gravity, and p its horizontal distance from the point L. If mv be the force of the recoil, R and C the pressures exerted by it upon the wheel and trail respectively, we have the relation

$$mv \sin \theta = R + C.$$

The horizontal component acts to overcome the friction of the wheel and trail, and to set the carriage in motion. By making f the unit of friction, and MV the quantity of motion impressed on the carriage, we have

$$mv \cos \theta = f(C + R) + MV;$$

or, by substituting the value of $R + C$ from the above equation, and solving with reference to V, we have

$$V = \frac{mv(\cos \theta - f \sin \theta)}{M},$$

which is the velocity of recoil. As the unit of friction of the wheel and trail are not exactly the same, the foregoing equation will not give a strictly correct value for V for field- and siege-carriages, but it will be correct for fortress carriages and mortar-beds, which do not move on wheels, in recoil. The force mv also acts to rotate the carriage around the point L with an effect proportional to its lever-arm Ld, which is equal to $a \sin dvL$; but $\sin dvL = \sin [180° - (\alpha + \theta)]$, and the moment of the force of the charge, with reference to the trail, is $mva \sin [180° - (\alpha + \theta)]$. This moment being equal to the moment of the weight of the piece, and the moment of the quantity of motion impressed upon the carriage, or P, we have

$$mva \sin (180° - \alpha - \theta) = Wp + P.$$

But $P = \frac{Wk^2w}{g}$; k being the radius of gyration of the gun and carriage taken with reference to the trail, g the force of gravity, and w the angular velocity of the gun and carriage. Substituting this value of P in the above equation, and reducing, we have

$$w = g\frac{mva \sin (180° - \alpha - \theta) - Wp}{Wk^2}.$$

With this relation we can discuss, by giving different values to θ, α, a, and p, the effect of the angle of fire, length of trail, position of trunnions, and center of gravity, on the stability of the carriage, or the resistance which it offers to overturning by the force of the charge acting at the center of the trunnions.

Stationary carriages consist of two parts, the carriage—or, as it is usually called, the top-carriage—and the chassis, and, with the exception of that for the flank-casemate howitzer, are always constructed of wrought-iron. The top-carriage is composed of two cheeks, held together by two plates of boiler-iron, called the front and rear transoms. Each cheek is formed of two plates of boiler-iron cut to a triangular shape, separated by interposing at the edges the vertical portion of a T-shaped bar. The horizontal branches project over each side to form a double flange, giving stiffness to the cheeks. Flat bars of iron are placed between the plates at suitable intervals to stiffen the cheeks in the direction in which the weight and recoil of the piece bear upon them. All these parts are held together by screw-bolts. The piece rests between the cheeks, and is supported on them by the trunnions, which work in circular cavities called *trunnion-beds*. This permits the piece to have free play for purposes of elevation and depression.

For most pieces, the motion of the top-carriage to and from battery is regulated by a pair of truck-wheels, one on each side, which work on an eccentric axle placed underneath and a little in front of the axis of the trunnions. The wheels are thrown *into gear* by means of handspikes inserted into sockets upon the ends of the eccentric axle; the wheels then rest upon the top of the chassis-rails, and only the rear part of the soles of the top-carriage rest on the chassis-rails and have sliding friction. The wheels are thrown *out of gear* in the same manner; the entire soles then have sliding friction upon the chassis-rails, thus checking recoil. In the 15-inch gun-carriage there are two pairs of truck-wheels, one pair being placed in front, as just described, and the other pair near the rear end of the carriage; the rear wheels only are on eccentric axles, and when these are *out of gear* the soles of the top-carriage rest fairly on the chassis-rails, and the motion is on sliding friction. When the rear wheels are *in gear* the front wheels also touch the chassis-rails, and the top carriage moves on rolling friction. To prevent the rear wheels from working *out of gear* while the gun is being run from battery, or jumping *in gear* when the piece is fired, pawls are provided for locking the rear axle.

When the rear wheels are *in gear*, motion is communicated to the carriage by means of a handspike on each end of the front axle. This handspike carries a double pawl, which works in ratchets or cogs on the truck-wheels. The handspike is arranged with a counterpoise, consisting of a heavy piece of iron on the short arm of the lever. In the 10- and 15-inch guns, as also in mortars, the elevation and depression are given by means of a lever, called the *elevating-bar*. The point of this bar works in ratchets cut in the breech of the piece. The fulcrum—usually called the *ratchet-post*—rests on the rear transom of the gun-carriage. It is of cast-iron, and has several notches for adjusting the position of the elevating-bar. Carriages for the 8-inch rifle (converted) have an improved elevating-apparatus. Guns of the Parrott pattern have an elevating-screw. This is attached to the rear transom of the carriage at its lower end, while the nut is connected to the cascabel of the gun. The screw is worked by a handle passing through it above the nut. Both screw and nut admit of movements by which the screw can take any position required in the various degrees of elevation. See *Chassis, Field-carriages, Ordnance, Sea-coast and Garrison Carriages, Siege-carriages*, and *Traveling-carriage.*

GUN-CARTRIDGE.—A bag in which the charge of powder is placed before the cartridge is inserted in the gun. The size and form of cartridges depend on the nature of the guns with which they are to be used, and the purpose for which they are required. They are made of serge, silk (a material made entirely from refuse silk), and raw hide—serge for service, silk for saluting or exercising, and raw hide for drill purposes. Experience has shown that serge is hardly strong enough for heavy charges; silk cloth, therefore, which is much stronger, is likely to take its place. Serge or flannel cartridges are hooped (stitched round with rings of thread or broad braid), which tends to keep them in their proper shape when filled. In examining cannon-cartridges (filled or empty) care should be taken to see that the flannel is perfectly sound throughout, and the sewing uninjured, and free from all appearance of moths. If filled, the powder should be free from all lumps or dust. Dust in powder in any package or parcel of cartridges will be shown by the flannel appearing black and dusty on the outside. To restore the cartridge, if the powder has become caked by pressure, gentle rolling will bring it to its proper state; but if it has been caked from wet, it cannot be restored without injury to the grain. Cartridges which are injured by moths, or have the flannel torn or damaged, or of which the powder has been wetted and caked, or which is very dusty, are unserviceable.

GUN-CONSTRUCTION.—The change from the former comparatively light smooth-bore gun to the heavy rifled cannon of the present day, throwing an elongated projectile of at least three times the weight of a spherical shot of the same caliber, has led to the almost entire abandonment of cast-iron, unaided by other metals, for gun-construction, and to the trial and adoption in its stead of metals of higher tensile strengths and elastic limits, as forged iron and steel. It is true that the Italian military authorities, and especially those of France, have experimented quite extensively with combinations of cast-iron and steel for heavy guns with good results; the present naval and sea-coast armament of the latter nation being made up in great part of such guns.

It seems, however, that neither of these nations is disposed to rest satisfied with this combination of material for gun-construction. In fact, the French have instituted trials with all steel, and recently with steel wire-wrapped guns. Herr Krupp's rifled guns are made solely of forged steel. They have been adopted in Germany, Austria, and by some of the minor Powers of Europe. Though the Armstrong and Woolwich guns are constructed essentially of wrought-iron, we infer from various sources that English opinion, in common with that of the Continent, points to the use of steel in some shape as the future material for heavy guns both for land and naval service. The combinations of this material, as well as those of wrought-iron, known as the built-up system, thus far tried with more or less success, consist of a lining tube surrounded by concentric rings or cylinders of greater or less length, connected together by methods varying with the ideas of the designers, as in the Krupp, the Woolwich, and the Armstrong systems.

These different systems all agree in this, that the assemblage of parts shall produce compression upon the inner layers and extension upon the outer, so as to call forth in the most effective manner the resistance of the several rings when subjected to the strains due to the explosion of the charge. Though long since a recognized fact that the penetration of projectiles into iron increases far more rapidly with velocity of impact than with weight of shot, it is only within a few years that changes in gun-construction have been initiated looking to a large increase of initial velocities. These recent changes have involved great increase in the length of gun and in the capacity of the powder-chamber, by which means about one third additional velocity of projectile has been reached, and, notably, in the 9.45-inch Krupp gun, and in the wire-bound Armstrong gun recently constructed and tried, about one half. The leading military nations of the world, though already provided to some extent with guns of medium power, more or less satisfactory, are now looking for such combinations of metals as will produce a stronger gun capable of burning a very large charge of powder so as to attain the highest possible initial velocities with safety.

Steel in some form seems to be regarded as the best metal to accomplish that end. The fact that steel wire can be produced with more than twice the tensile strength of steel forged as rings has probably induced the recent construction, for trial, of wire-bound guns both in England and France. It is understood that so far as these trials have progressed the results are favorable, indicating the attainment of high velocities. Now, the forging of the large masses from which the rings are produced by boring, that constitute the successive layers of the steel gun, involves a very expensive plant, is a very slow and costly process, and does not result uniformly in the attainment of a perfectly homogeneous metal. It would therefore be economy and probably give better results if the outer layers of the gun could be replaced by steel in a shape more readily produced and possessed of greater tensile strength. It is in part with this view that steel wire seems to have been suggested for wrapping under initial strains the interior tube and next consecutive concentric bands of the steel gun. The wire by its great tensile strength cannot fail to impart the requisite tangential strength to the structure. The only apparent difficulty of the combination is in the parts that give resistance to longitudinal strains developed in the firing. Dr. W. E. Woodbridge, who seems to have been the inventor or suggester of the wire gun, has attempted to attain resistance to transverse rupture, other than that due to the great friction of the parts, by uniting them by brazing with bronze. In Sir William Armstrong's wire gun, resistance to longitudinal strains is effected by the introduction of lengthwise layers of steel wire surrounding the barrel between layers of the wrapping wire, and in Schultz's gun the breech is bound to the trunnion-ring by round bars of steel.

It is claimed by the representatives of cast-iron in this country that it has never been tested using the slower-burning and large-sized grained powders now in vogue. Guns, made of any material, should evidently be so constructed in dimensions and chambering as to cope in power and effectiveness with their rivals, caliber for caliber. In order to do this, large charges would necessarily have to be employed with cast-iron, and however judiciously air-spacing and chambering may be done, and even using the most perfect powders, the pressures resulting from the large masses consumed would rise beyond what is ordinarily deemed a safe pressure (17.1 tons per square inch), even for guns using steel and iron. To illustrate: The two Armstrong 10.236-inch wire guns have been fired 60 rounds, and the pressures have been 67,000 pounds per square inch. This is not deemed by authorities on these matters as safe for any of the ordinary constructions now in use, and cannot hence be regarded as by any means a safe one for cast-iron, however thick the walls are made within the limits of reasonableness of weight, and hence, although its use might have been entertained as possibly a safe structure some time since, when large charges in stronger gun-constructions did not obtain, the conclusion has now to be drawn that no good reasons, even on the grounds of insufficiency of trial, exist for the further test of the metal which, owing to high pressures, will be unable to cope in power, gun for gun, with stronger systems susceptible of enduring the enormous strains arising from heavy charges, and which are beyond the capacity of any cast-iron to withstand.

It is not understood that any important modifications are at present intended in the general features of the present constructions using wrought-iron exterior tubes, the change being confined principally to the substitution of the one metal for the other. The change has, however, so far progressed and been so well established as an improvement, that steel coils for 80-ton guns have already been produced at Woolwich, and applied in the more recent fabrication of these heavy pieces; the heaviest products, in fact, as yet turned out by the Royal Gun-factory. See *Armstrong Guns* and *Ordnance*.

GUN-COTTON.—The prevailing sentiment in military circles on the Continent is adverse to the use of this powerful explosive. This opinion is based on the belief that the substance is not a stable one, but is liable, under the ordinary circumstances attending its use for military purposes, to spontaneous combustion. A claim for reliable stability was set up for it in 1862 by Baron General von Lenk, who contended that gun-cotton when carefully prepared and thoroughly cleansed from all remaining free acid is as stable a compound as gunpowder; but the subsequent explosion in Austria of a magazine in which both gunpowder and gun-cotton were stored did not fail to excite suspicions against the latter as being in some way implicated in the explosion, which could not be otherwise satisfactorily explained, to turn the tide of public opinion against the new compound, and confirm the doubts which had previously existed, whether it possessed in a sufficient degree the quality of stability, without which it could not be trusted. The experiments commenced in 1863 by direction of the English Government to test thoroughly, upon a large scale, the question whether gun cotton, prepared after the process of General Lenk, possessed the required stability to warrant a sure confidence in its remaining indefinitely in an unchanged condition when subjected to all of the changes of temperature that it would meet with in actual service, have been so entirely satisfactory as to lead to its general use for destructive effects in mines, torpedoes, etc. In order to remove all trace of free acid from the gun-cotton, which is an absolute essential in all cases, the process of General von Lenk required long-continued washings in running water, sometimes extending over several weeks, to accomplish thoroughly this prime requisite. The capillary action of the long fibers of the cotton formed a great barrier to the ready and complete removal of the acid, and consequently the operation of washing was a long, tedious, inconvenient, and uncertain one. Professor Abel, the Chemist of the War Department, to whom was committed the chemical and manufacturing part of the investigations, made several important improvements in the process of manufacture, chief of which is the reduction of the gun-cotton to a state of pulp. This, though originally adopted for another purpose, has much improved its quality, especially in regard to stability, which has been greatly assured by the more thorough and complete means of getting rid of the free acid, while the long washings in running water have been avoided, and the time required for the whole process of manufacture reduced from three or four weeks to as many days. The terrific accident which occurred at Messrs. Prentiss's works at Stowmarket in 1871, where gun-cotton was being manufactured for the Government, and when 13½ tons were exploded, would have destroyed all confidence in its stability and caused its use for military purposes to be discarded forever after; but it was conclusively shown, after a thorough and searching examination into the causes of the accident, that the explosion did not result from spontaneous combustion of the gun-cotton as it came from the last operations of the manufacture, but was caused by impure gun-cotton, rendered so by acids which had been poured on it willfully by some unknown persons after it had passed through the finishing processes. The evidence taken at the examination is conclusive, and the experiments made in England, on which this evidence was based, go to inspire entire confidence in the stability of gun-cotton when it has been carefully prepared. Samples which have been subjected for eleven years or more to every degree and change of temperature that would be encountered in actual service in any known climate show no appearance of change, but remain in exactly the same state as when first made.

Experience has shown that in the manufacture of gun-cotton it is a matter of the greatest importance for the success of the process and the reliability of the product that the manufacture should be conducted with the greatest care and circumspection; and to secure this it is desirable that it be in the hands of responsible persons who have no interest in slighting any part of the work. Impressed with the importance of adhering closely to the minutest detail in the different operations, the necessity for which was brought out clearly in the investigation above referred to, the English Government determined to establish a gun-cotton factory under the immediate supervision of army officers, and accordingly one was established at Waltham Abbey, under the direction of the Superintendent of the gunpowder-mills. In all of the various stages of manufacture the gun-cotton is in a wet state, entirely harmless, and the manipulations unattended with danger. It is not necessary, therefore, that the buildings should be removed at a great distance from each other, as in a gunpowder-factory, but, for the convenience of furnishing the necessary power to drive the machinery, the buildings, built of brick, are placed near together, like ordinary shops, with a steame-engine for the motor. The material required by Von Lenk's process for making gun cotton was raw cotton of long staple and high quality; but Professor Abel prefers to all others the waste cuttings from spinning-machines, such as is used in workshops for cleaning machinery, for the reason that it has already undergone so thorough a cleansing in the process of spinning through which it has passed that it requires no further purification to prepare it, and the gun-cotton made from it is free from those impurities foreign to cellulose, which are removed from the raw cotton with so much difficulty, and are apt to form with the acids products of somewhat an indefinite and comparatively unstable nature, and become the initial points of any change or decomposition which might be started by long exposure to high temperatures. The points to be particularly attended to are to see that the waste is entirely free from impurities, such as portions of seed-husks and foreign substances, and is thoroughly dry. The waste is received in bales, the cotton in a rough tangle. It is first picked over by hand, to remove all impurities that can be thus culled out, and is then passed through a machine which, by means of toothed rollers, opens and loosens the cotton, and subjects it to the strong blast of a fan, which blows off other foreign matters. Raw cotton at ordinary temperatures absorbs from the atmosphere about 6 per cent of moisture. To remove this thoroughly the cotton-waste is subjected to a temperature of 126° for the space of 20 minutes. For this purpose a drying-chamber, long and narrow, is made of boiler-plate, covered over on all sides with a non-conductor, to keep in the heat, and for economy of labor and fuel is so arranged that its action shall be continuous and not require to be stopped to introduce or remove the cotton. It is heated by air which has just been in contact with coils of hot pipes, through which steam is kept circulating. The necessary ventilation is provided to carry off the moisture. It is provided with five horizontal endless belts running from one end of the chamber to the other, one above the other; to each of which is communicated a slow motion by the machinery, acting by means of belts on pulleys outside of the chamber, fixed to the same axles as those on which the endless belts move. The cotton is fed by hand into a trough in the picking-room, and passes thence to an endless belt, which conveys it to the upper belt in the drying-chamber. This belt carries it through the length of the chamber and deposits it on the next lower belt, which performs a corresponding service, and so on to the last, which leaves it in a close closet prepared for its reception. The cotton, now thoroughly dry and warm, is weighed out in parcels of 1½ pounds each; and, to prevent it from absorbing moisture from the air before it is used (it cannot be dipped in the acids until it has cooled), it is placed in tin boxes, with closely-fitting covers, and stored away until cool and ready for use. The acids are procured by contract from private manufacturers. It is particularly required that they should be in a highly concentrated state and of uniform specific gravity, the nitric acid 1.52 and the sulphuric acid 1.85. The presence of hyponitric acid in the former (from which, when concentrated, it is with difficulty eliminated) is not regarded as an objectionable impurity. The acids are thoroughly mixed together in the proportion of three of sulphuric to one of nitric, by putting a certain weight of nitric acid into one tank, and into another of equal height three times the weight of the sulphuric acid. These two tanks are provided with outlet-pipes which will empty both tanks at the same time. These outlets are brought together into a single pipe, which conducts the acids to a considerable distance into a third tank, in which there is a mixer, to which motion is communicated by means of a pulley on the outside. After the acids are well mixed together, they are forced into tanks above the dipping-room, where they remain well covered for a considerable time before being used—in all cases until their temperature, which was raised by mingling the acids together, has been reduced to that of the atmosphere.

The immersion of the cotton in the acids gives rise to active chemical action, that of the nitric acid upon the cotton, and this with the union of the acids with the liberated water causes the evolution of considerable heat which it is necessary to control and regulate. To carry off and keep down this heat, the vessels in which the cotton and acids are brought together are surrounded by cold water. A large deep trough extends along one side of the dipping-room, and a stream of running water is kept constantly passing through it. In this trough is placed a long row of tanks, each some 14 inches wide, 2½ feet long, and 16 inches deep. These are kept filled with a certain measure of acid, into which the 1½-pound charges of cotton are dipped. The partition-wall along the line of tanks has a row of holes cut in it, each large enough to pass a charge of cotton through it into the dipping-room. The holes are about 8 feet apart and are provided with close shutters, which are kept closed except when required for the delivery of cotton. Each workman is charged with three consecutive tanks, which he uses for dipping. He fills the first to a fixed height with the acids, raps on the shutter for a charge of cotton, which is passed by an attendant from the tin box in which it has been kept through the hole into a wooden scoop ready to receive it, from which the workman takes it and plunges it into the acid and leaves it there. He then proceeds to the second tank, and goes through the same operation, and afterward the third tank. By this time the cotton which was dipped first, having been in the acids a sufficiently long time, is taken out with a long iron fork and laid on an open grate at the back of the tank, where as much of the acid is removed as can be pressed from it with the fork, using it for this purpose as a lever, and engaging the end under a cross-bar placed in rear of the grate. The charge of cotton is then placed in an earthen jar, covered with an overhanging cover of the same material, and deposited in the soaking-room, where it remains for twenty-four hours standing in a basin of water. The cotton has absorbed and taken with it about eleven times its weight of acids. The workman replaces this amount with fresh acid, immerses another charge of cotton in it, leaves it, and proceeds to the next tank to go through with the same manipulations as at the first, and so on to the others, taking each in its regular order of succession and going through exactly the same motions. By this process of saturating the cotton in the acid the greater part of the former is converted into trinitro-cellulose, but there are generally some portions which escape, to a certain extent, this change; therefore, to insure the conversion of the entire mass, the cotton still containing an ample sufficiency of acids to continue the chemical action upon the fibers not yet acted upon is set away in earthen jars to give the necessary time to complete the change. A considerable amount of heat is still generated by this action, and, to carry it off and prevent its accumulation, the jars containing the dipped cotton are placed in cold water of a depth equal to three fourths their height. The soaking-room has its floor laid in concrete and cement, and is divided into several shallow basins, which will contain each about fifty jars, and are capable of being readily filled with water to a depth of 6 or 8 inches, and emptied at pleasure. The cotton is kept here for twenty-four hours, during which time especial pains must be taken to prevent in every way the addition of the least water to the cotton, as the result of such accident would be its ignition and entire consumption. In such cases strong nitrous-acid fumes are evolved, and the jar is removed to the open air, where the cotton is quietly consumed without other damage than its loss.

The next operation is to get rid of the free acid contained in the cotton. This is effected, first, by means of the centrifugal drying-machine, which is 30 inches in diameter and makes 1500 revolutions per minute. The contents of five or six jars are emptied into the centrifugal machine, and the charge is uniformly distributed before the machine is set in motion. When the acid ceases to drop from the cotton the latter is taken out of the machine, and a greater portion of the remaining acid is removed and the chemical action arrested by washing in fresh water. Care is to be taken at the first washing that the cotton is plunged quickly, in small quantities at a time, into a large body of fresh water, in order to avoid the danger of ignition. The first washing is performed in a large tub, in one end of which there is a wooden wheel which plunges the cotton, in small portions at a time, into the water, and submerges it at once. From this tub the cotton is taken to another centrifugal drying-machine, by which the water is removed, when it is again washed and dried in the same manner. The cotton is next carried to the pulping-machines to be reduced to pulp. These are essentially the same as the ordinary machines used for producing pulp for paper, and do their work in the same way. The pulp next runs into the poaching-machine, where all of the remaining free acid is removed by continuous washings in fresh water, and finally at the close in water made slightly alkaline. The poaching-machine is a large trough, 24 feet long, 12 feet wide, and about 5 feet deep, with a large wooden wheel, like an ordinary water-wheel, of 2½ feet width of face, placed in the middle of, and parallel to, the longer side of the trough. Pipes are provided for furnishing a continuous supply of pure warm water and carrying off the surplus, as well as for conducting the pulp to and from the trough. A rotary motion is communicated to the wheel, which stirs up and keeps the pulp in constant commotion, dragging it down at one end and forcing it out at the other, at the same time assisted by workmen who, with long wooden scrapers, push it forward where it will meet the action of the wheel, thus bringing every particle in contact with fresh water and washing it in the most effectual manner. This operation is continued uninterruptedly, the water being constantly changed, until samples of the cotton will sustain satisfactorily a severe heat-test; this generally requires about 48 hours, though it may require 100 hours. At least a half ton of gun-cotton is washed at one time in the poaching-machine, and by this means the products of many different dippings are most intimately mixed together, so that the greatest uniformity in the material is attained. Before being taken from the poaching-machine the gun-cotton is washed in water rendered slightly alkaline with the carbonate of lime and soda. It is desirable that the gun-cotton should contain as much as 3 per cent of these mineral substances. The manufacture is now completed, so far as relates to the giving of the cotton its explosive properties and its resistance to further change under the ordinary circumstances of service and use. Great care is required, even to the minutest detail of manufacture, to insure a product of uniform quality, and it is insisted upon that too much stress cannot be laid upon the fact that deviations from the prescribed process, which may appear at first sight trivial (such as a slight variation in the strength of the acids or the neglect of proper cooling arrangements), are certain to lead to varieties in the gun-cotton produced affecting its explosive character or its stability, or even both.

In order to control the explosive power of gun-cotton it is necessary to compress the pulp into homogeneous masses of required form and density. For mining purposes and for torpedoes it is formed into circular disks, 3 inches in diameter and 1.75 inch thick, of a density slightly greater than water at 60° F., between 1 and 1.003, and each disk has two holes bored through it about .2 inch in diameter. To form these disks the pulp is drawn from the poaching-machine into a large, close iron tank called the stuff-chest, which, for convenience of drawing off the pulp, is placed on a level above the machines used for pressing the disks. It is supported on iron columns about 9 feet high, and being also on a higher level than the poaching-machine the pulp has to be raised into the stuff-chest by first exhausting the air from it. It is provided with a wooden wheel, which, in revolving, keeps the pulp stirred up in constant motion and prevents it from settling and separating from the water in which it is held suspended. A pipe in the bottom of the stuff-chest conducts the pulp into the machine for forming the disks. This machine is constructed on the same principle and worked in the same manner as that used and described for pressing pellet-powder. The mold-plate in this case is a large bronze cylinder, about 15 inches long, and has 36 holes about 2½ inches in diameter bored through it. It is stationary, and made fast to the frame of the machine. A corresponding number of closely-fitting bronze plungers enters these holes from below and closes them at the bottom. These plungers are made securely fast at their lower end to a plate which is moved up and down by a hydraulic press, and are pierced with small holes running through them parallel to their axis. The object of these holes is to afford a way of escape to the water in the pulp when it is subjected to a heavy pressure. These plungers are first partially withdrawn a certain distance, so that the molds shall contain a certain fixed volume; the latter then are filled to the top with pulp from the stuff-chest, and are closed on top by means of an overhead block. The plungers are now forced upward by the pumps, and the pulp is compressed into a solid cake, the water escaping from it through the plungers. The overhead blocks are now removed, and, the plungers continuing their upward motion, force the gun-cotton out of the molds in shapes of short, compact cylinders. They are then carried to the next machine, which is similar to the first, except it has only four molds, 3 inches in diameter; in each of these three cylinders of gun cotton are placed, separated from each other by circular iron plates, the edges of which are cut obliquely, with shallow channels to permit the water in the cotton to find its way out. The pressure brought to bear on each plunger is 15 tons, and the short cylinders of gun-cotton are pressed into disks 3 inches in diameter, 1.75 inch thick, and weigh 9 ounces each. The gun-cotton still contains 20 per cent of moisture, and can be sawed or bored with perfect safety, or placed in the flame of a candle, or bored with a red-hot iron without danger. Each disk is bored with two holes about .2 inch in diameter, parallel to the axis, and disposed symmetrically on either side of it. Gun-cotton is packed in water-tight boxes, containing about 20 pounds each. As many disks are put in as the box will hold, which is then filled with water, and permitted to stand for some minutes, when it is poured off and the cover securely screwed down. It may be kept with entire safety in this condition for an indefinite period, and be transported without danger or fear of accident, in any conveyance, having in this respect the advantage over gunpowder or most other explosives. The discovery made by Professor Abel, that wet gun-cotton can be fired with the same effect as if it were dry, if there be present a small portion of the dry cotton, and it be exploded by a detonating fuse, is a most valuable one, inasmuch as it obviates the necessity of drying it, the only operation in the process of manufacture that is attended with any danger. Besides, it diminishes the liability to accidents in transportation and in use, as the damp cotton is perfectly uninflammable so long as it remains damp. It is necessary to dry only a disk or two for each separate mass to be exploded, and this may be done safely on hot plates which are freely open to the air at the sides. The factory at Waltham Abbey has the capacity to turn out 4000 pounds per day, and is usually making about 1500 pounds per day. The cost of manufacture is stated to be 42½ cents per pound. Experiments are being made to test its fitness for bursting-charges for shells and rocket-heads, for which purposes it is thought to possess advantages over gunpowder. See *Explosive Agents* and *Gunpowder*.

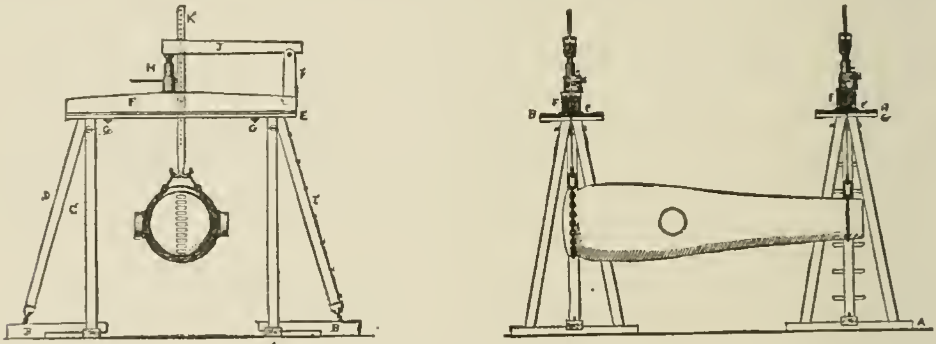
GUN-DETACHMENT.—The men employed in the service of artillery are called artillerymen, and those for a single piece constitute a *gun-detachment*, varying in number with the size and kind of piece. The gun-detachment is composed of two non-commissioned officers and from two to ten privates. The senior non-commissioned officer is called the Chief-of-detachment; the other, the gunner. The privates are called cannoneers.

GUN-FIRE.—The well-known name in the army, proclaiming the break and close of day by the firing of a gun; in the former case troops turn out and prepare for the forthcoming duties of the day, and in the latter all night-duties commence. See *Tattoo*.

GUN-LIFT.—A contrivance for moving, mounting, and dismounting heavy guns. It is variously constructed. The gun-lift generally employed in the United States service is shown in the drawing, and is described as follows: A is the *sill*, with mortises to receive the legs of the trestles; B, is the *brace-sill*, notched to fit on the sill, with a bolt and key to secure it in its place, and a cast-iron seat for the end of the adjusting-screw of the brace to rest in; C, the *legs* of the trestle, bolted and keyed together at the top; D, the *brace*, with adjusting-screws attached to the foot, and cleats to form a ladder; E, the *cap*, with a shallow mortise near each end to receive the ends of the legs and braces, and a hole to receive a large bolt for securing it to the legs. These bolts are keyed below, and their heads project above the cap about three inches, and serve as dowels to secure the bolsters; F, the *bolsters*, resting on the cap, having a clevis at the center of gravity for hoisting it in position, and mortise for the hoisting-bar to pass through; G, the *bracket*, fastened to the cap by a bolt, around which it turns; H, the *staging-plank*, resting on brackets; I, the *fulcrum*, resting in the mortise in the bolster; J, a *lever*, one end resting in the fulcrum and the other end on the hydraulic jack, and having a mortise through which the hoisting-bar passes; K, the *hoisting-bar*, with hooks on the lower end for sling-chains, and holes at intervals to receive the supporting-pins; L, *shears*, for hoisting into their places the bolster, levers, fulcrums, and jacks; M, *hydraulic jack*, for raising the end of the lever, and thereby the weight. Each gun-lift is provided with two sets of caps and bolsters. One of these sets has the mortises for the hoisting-bar through its middle; this is intended for center-pintle carriages. The other set has mortises much nearer one end than the other, and is for front-pintle carriages. The latter arrangement is intended to permit the carriage to be traversed from under the gun, when it is raised, or under it, when it is being mounted. When weights are not excessive—that is, not exceeding, say, fifteen tons—and can be slung with a single sling, but one trestle need be used. This would be the case with mortars, gun-carriages, and like weights. The jacks used must be of a power equal to the weight to be raised, as there is nothing gained for them by way of leverage.

Twelve men are necessary to erect the gun-lift and mount or dismount a 15-inch gun. The implements specially required are two *hydraulic jacks* (30-ton, or one 30-ton and one 15-ton), two *mauls*, two *hammers*, one *measuring-rod* (12 feet), one *spirit-level* (carpenter's). If the carriage and chassis are to be moved, quired, by turning the screw in the foot, until they shall have a good bearing when the legs are vertical, which is determined by a plumb-line or spirit-level. To raise the bolster a pair of light shears is provided. Place them so that when raised the head shall be over the middle of the cap of the trestle; hook the pulley-hook in the link provided for the purpose; fasten two guys to the head, one to the front and the other to the rear; raise the shears and make fast the guys; hook the pulley to the clevis of the bolster, and raise it to its place on the cap; raise the staging-plank and lay them on the brackets. Two men ascend the steps on the brace to the top of the trestle and receive the fulcrum, lever, and jack, which are hoisted to them in turn, and place them in position. The hoisting-bar is brought by the men on the ground, who insert it into the mortise in the cap and bolster, and raise it, assisted by those on the trestle, until it be in position.

To raise the weight, pass a sling around the weight, bringing the ends over the hook on the end of the hoisting-bar, taking in all of the slack. Bring the lever down on the head of the jack; put in the pin over it and through a hole in lifting-bar; commence pumping, and raise the weight the full lift of the jack; insert the pin in the hole in lifting-bar above the bolster and run down the head of the jack as far as it will go; bring the lever down as at first, and



Gun-lift.—United States Army.

the following will be required in addition: one *cradle* (or truck-wagon), six *cradle-rollers*, twelve *wheel-chocks*, four *way-planks*, two *shifting-planks*. A sufficient number of 44-inch blocks of various thicknesses should be at hand for any purpose required of such material.

To assemble and raise the gun-lift, place the sills parallel to each other at the required distance apart, and on the spot where the trestle is to stand. It will be convenient to have a wooden rod of a length equal to the proper distance between the sills. Lay down the brace-sills and key them; take two legs, bring together the two ends which form the miter-joint, pass the bolt through them, and drive in the key; raise one leg above the other, insert the head of the legs into the mortise in the cap, put in the bolt, and drive in the key. At the same time two other men have gone through the same operation with the other two legs. Place the ends of the legs that are on the ground close to the mortises in the sills; all take hold of the cap and raise it, bringing the trestle on its feet, and placing the legs in the mortises in the sills. A pole with a notch in the end, or hook like a boat-hook, will be convenient in raising the trestle after the cap is too high to hold it with the hands; or the trestle may be raised by the shears in the same way as the bolster, if the party be deficient in force, or if for other reasons it be deemed desirable. Correct the position of the trestle, if it be necessary, so as to bring the mortise for the hoisting-bar directly over the center of gravity of the weight to be raised. Put up the braces, varying their lengths as may be re-

continue this operation as already described. *The weight should not be left on the jack for any length of time, but on the pin.*

To mount a 15-inch gun with this gun-lift, bring the gun on to the platform by means of the cradle, or truck and portable railway, the muzzle to the front, the vent uppermost, and leave it in such a position, with the muzzle about two feet in the rear of where the end of the chassis will come, that when the gun shall be raised vertically the carriage can be placed on its pintle and directly under the gun; place the shears midway between the place where the two trestles are to stand; raise the trestles and place them over the gun so that one hoisting-bar shall be over the center of the neck of the cascabel, and the other about two feet from the muzzle; raise the gun to its full height as already described for raising a weight; remove the truck, bring the chassis (on a truck), and run it between the legs of the trestles under the gun; remove the truck and place the chassis on the pintle; bring the top-carriage and place it on the chassis, placing the trunnion-beds under the trunnions; lower the gun into its place, and remove the gun-lift.

If the gun and carriage be already on the platform, or if the peculiar position of the platform be such as to render the foregoing method impracticable, the following plan may be executed: Place the gun in such a position that the axis of the bore shall be in the same vertical plane as the central line of the chassis when the latter shall be in place; move the chassis parallel and close to the gun, the top-carriage run well to the front; put up the trestles over the gun and chassis, both of them being between the legs of the trestles; hoist the gun, raise and slide the chassis by means of the jacks under the gun and over its pintle; run the top-carriage back under the gun, and lower it into its place. See *Krupp Gun-lift* and *Prussian Gun-lift*.

GUN-MAKING.—Although the terms gunnery and gun relate chiefly to great-guns or cannon, the word *gun-making* is always applied to the manufacture of small-arms, comprising muskets, rifles, pistols, and carbines. In England the great seat of this trade was formerly London, whose workmen stood unrivaled throughout Europe for the excellence of their production; but of late years the gun-makers of Birmingham have succeeded, from local advantages, in turning out barrels of proved power, at such a price as to defy competition. Since then the London makers have confined themselves to "finishing," or putting together, an art requiring the utmost nicety; and even in this the skilled labor of Dublin and Edinburgh has now nearly equaled them. There are, therefore, several centers now in the United Kingdom whence first-rate arms are to be obtained. America and the leading Continental Nations are great manufacturers also, and each has its particular excellences. The chief Continental Gun-factories are at St. Etienne, Liege, Vienna, and Suhl.

Machinery has been comparatively slow in being applied to the manufacture of small-arms, but during the last few years it has made giant strides; and now the government manufactory at Enfield, in which numerous ingenious machines have been introduced from the United States, is fitted with every mechanical appliance, and can turn out many thousand arms per annum, each of which so exactly corresponds to pattern that all the constituent pieces are interchangeable. Barrels, instead of being forged by the hand-hammer, are rolled at once with a uniform pressure, and then welded at one heat. In the United States, barrels are at present made of cast steel, first formed in the solid, and then bored by a succession of borers of increasing diameter. These cast-steel barrels are rapidly superseding all others—at least for sporting purposes—in Great Britain, France, and America. Another favorite modern material for barrels is laminated steel. Barrels well constructed of laminated steel resist a bursting pressure of 82,000 lbs. on the square inch one eighth of an inch thick, whereas common "twist" barrels will only withstand about 34,000 lbs.

When the barrel is finished, however made, it is proofed, under very heavy charges of powder. All non-government barrels made in England must be proofed at the proofing-houses of London or Birmingham; government arms are tested at Enfield. The portions of the lock are made some of iron and some of steel, either forged by hand, or, as in the great manufactories, stamped out by a powerful machine. The stock is turned by machinery from strong light wood. On all accounts taken together, it is found that no wood is so well adapted as Italian walnut. The finishing or putting together of guns is an art in itself; the utmost attention having to be devoted to everything that will secure solidity, lightness, and the most minute accuracy of fitting. Skilled artificers in the gun-trade command excellent wages; rarely less than 40*s.*, and often as much as £4 per week.

In fitting and finishing, London is generally admitted to stand unequaled; Paris, however, making a good and near second. For barrels, Birmingham, St. Etienne, and Liege have the most repute. In all respects, Toledo, once famed for its blades, holds a high character in regard to its guns, both for sporting and military purposes. In the United States, Windsor and Hartford are the leading manufactories, with Springfield for government arms; but the quality of American workmanship is too often sacrificed to cheapness in the article turned out. The British export trade in small-arms is very great, the return for the year 1875 showing an exportation of 318,901 stand of all varieties, of the value of £655,169. See *Fabrication of Small-arms* and *Royal Gun-factories*.

GUN-METAL.—An alloy of nine parts of copper and one part of tin, used for brass cannon, etc. The term is also applied to certain strong mixtures of cast-iron. See *Bronze*.

GUNNELS.—A term sometimes applied to the *saddles* of a ponton-bridge. Commonly written *Gunwales*.

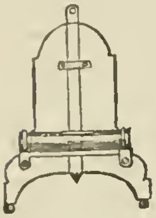
GUNNER.—A soldier, usually a non-commissioned officer ranking next to the Chief-of-detachment, employed to manage and discharge great-guns. In the United States service there is one gunner with each gun-detachment. In line, and in column of platoons, he is two yards in rear of the center of his detachment, except when belonging to the left detachment of the battery *in line*, or of platoon when in *column of platoons*,—in either of which cases he places himself on the left of the front rank of his detachment, and is the guide of that flank of the battery or platoon; in column of detachments, he is on a line with the front rank of his detachment, on the flank towards which the wheel was made, and one yard from it; in column of files, he is as if he had faced with his detachment from line. When he is the left guide of the battery or platoon, and by facing about the front becomes the rear rank, he does not quit his position on the flank of his detachment, but steps forward into the rear (now become the front) rank. When, by wheeling about, the right subdivision becomes the left, the gunner who was the left guide resumes his place in rear of his detachment, and the gunner of the detachment which has now become the left places himself on its left flank as guide of the battery or platoon.

In the British army, the gunner is a private soldier of the corps of artillery; he receives pay at the rate of 1*s.* 2½*d.* per diem. His uniform consists of blue with red facings, and red stripes on the trousers; and his arms consist of a carbine and sword-bayonet. At the present time, when artillery is used with the utmost skill and science, the training a gunner must undergo, to become thoroughly efficient, is long and arduous. His eye must be sufficiently acute to estimate distances instantly and approximately; and withal, he must possess physical strength capable of sustaining the exertions necessary for the service of heavy guns and the removal of shot and ponderous artillery stores. *Master-gunners* are pensioned Sergeants of artillery, who are placed in charge of the stores in small towers or forts; they are divided into three classes, of which those in the first class receive 5*s.*, in the second 3*s.* 6*d.*, and in the third 3*s.* a day. Master-gunners are now borne in the Coast Brigade of Royal Artillery, but the office has much degenerated in importance since it was first created, at least as far back as the time of Henry VIII.

GUNNER'S CALIPERS.—A small calipers made of sheet-brass, with steel points. The two branches are connected by a brass pivot, fastened on the upper side by a washer and screw. The branches are graduated so as to measure the lengths of fuses, the diameters of shot, and the calibers of guns. For measuring shot, the points are placed at the opposite extremities of a diameter, when the size of the shot is shown by the figures placed on a small arc on the circular part of the arm near the joint, the inner edge of the other arm, or a mark on it, coming in succession opposite the different points which mark the sizes. To measure the caliber of a gun, the position of the points is reversed; they are pressed against the sides of the bore at the extremities of a diameter, and the caliber is read off from the line, on a scale marked "guns," with which the back of the other branch coincides. The graduations on a scale next below the one marked "guns" will give the diameters in inches.

GUNNER'S GIMLET.—This implement is of the same form and size as the *priming-wire*, except that at the point a small screw is formed. It is used for boring out plugs which have been inserted in the vent, or the stems of the primers which may have become wedged in there.

GUNNER'S LEVEL.—An instrument for marking the line of metal on a piece. Until within a very recent period it was required with all pieces, but since the application of sights to guns its use is confined solely to mortars; and owing to the fact that these pieces are left rough and unturned on the exterior, the line of metal marked, in the usual manner, with a gunner's level and a chalk-line, is, at best, but a crude and imperfect method of obtaining a line of sight. The method of using this instrument is readily understood by an inspection of the drawing.



This instrument is frequently called the *gunner's perpendicular*.

GUNNER'S PENDULUM.—An upright frame of wood, having a cross-arm attached to it, from which a pendulum is suspended, vibrating seconds, consisting of a string with a leaden ball, measuring from the point of suspension to the center of gravity of the ball, a length equal to a second's pendulum having reference to the latitude; in latitude 22° the length is 39.1. It is employed to measure the time of flight of a mortar-shell.

GUNNER'S PINCERS.—When an obstruction in the vent projects beyond the surface of the gun, or has a head, it may be withdrawn with the *gunner's pincers*, which are made of iron with steel jaws, and have on the end of one of the arms a claw designed for drawing nails, etc.

GUNNER'S POUCH.—A leather pouch worn by the gunner, being attached to the person by a strap buckling around the waist. It contains the smaller implements required by the gunner when in action.

GUNNER'S QUADRANT.—An instrument for giving elevation or depression to a piece. It consists of a graduated quarter of a circle of sheet-brass, of six inches radius, attached to a straight brass bar twenty-two inches long. (Fig. 1). It has an arm carrying a

Fig. 1.

spirit-level at its middle, and a vernier and clamp-screw at its movable end. The arc is graduated to half-degrees, and the vernier reads to five minutes. To get a required elevation, the vernier is set at the indicated degree; the brass bar is next inserted in the bore parallel to the axis; the piece is then elevated or depressed until the level is horizontal. The elevation may likewise be obtained by applying the bar to the face of the piece, care being taken to have it in a plane parallel to the plane of fire. The latter is the mode of using it with mortars. The difficulty of applying the quadrant to the muzzle of guns, especially to those in embrasure, has suggested that a metallic ledge be attached to the end of a trunnion; upon this ledge the bar of the quadrant is applied when the elevation is to be given. The top of the ledge is parallel with the axis of the bore.

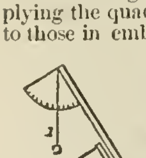


Fig. 2.

In another form, shown in Fig. 2, the quadrant is made of wood, and is attached to a rule two feet long. It has a *plumb-line* and *bob*, which are carried, when not in use, in a hole in the end of the rule covered by a brass plate. The quadrant is applied either by its longer branch to the face of the piece, or this branch is run into the bore parallel with the axis, and the elevating-screw turned or the quoin adjusted until the required degree is indicated. See *Mortar*.

GUNNERY.—Ignorance of the laws of gravity and of other physical circumstances affecting the flight of projectiles prevented any current theory of gunnery being arrived at in the earliest stages of artillery. The first author professedly treating on the flight of cannon-shot was Nicholas Tartaglia, a distinguished Italian Mathematician, who in 1537 published his work, *La Nuova Scientia*. He had no practical acquaintance with his subject, but his guesses were shrewd and often marvelously near the truth. Among other things he ascertained that no portion of the track described by a ball is a right line, and, as a practical aid to artillerists, he devised the gunner's *quadrant*. After Tartaglia, many philosophers, especially of Italy, theorized on the question, and various tables of ranges, elevations, charges, etc., had been published, all more or less fallacious, when a nearer approach to accuracy appeared in Galileo's *Dialogues on Motion*, printed in 1638. The officers who had charge of artillery in actual use were too little gifted with scientific education to deduce theory from practice; and up to the time of Robins, who wrote in 1742, but four working-gunners—Collado, Browne, Eldred, and Alderson, of whom the last three were Englishmen—have left treatises of any value on the use of their weapons. Galileo, in his contributions to physics, had shown that cannon-shot, or any other projectiles, being affected by the downward force of gravity, would travel in the curve of a parabola, unless affected by the resistance of the air. The philosopher pointed out modes by which the disturbances caused by this resisting medium might be ascertained; but subsequent writers, with the exception of Newton and Bernouilli, till the time of Robins, chose to assume that the atmospherical resistance was but nominal, and boldly asserted that all shot described parabolas in their course. In 1742, Mr. Benjamin Robins, who must be considered the real founder of the science, published his *New Principles of Gunnery*, a work the result of long and almost exhaustive experiments. He treated of the atmospheric resistance, of the force of gunpowder, of the effects of varying length and weight in guns, and of almost everything which in any way related to the motion of projectiles, carrying the theory of gunnery nearly to perfection. As one result of his experiments, Robins established the law that common shot encountered a resistance from the air during their passage, which increased as the square of the velocity, or very nearly so; and that their courses differed widely from parabolas. By means of the ballistic pendulum, he measured the speed of balls at the very cannon's mouth. Euler, in the latter part of the eighteenth century, added much to the knowledge of the subject by his commentaries on the work of Robins, as did also the mathematician Hutton.

The theory of gunnery, so far as it can be deduced from the universal laws of motion, without regard to the resistance of the air, falls under the more general head of projectiles. But except in firing bombs, which from their low velocity are not so much affected by the resistance of the air, the mere mathematical theory is of little service. All the real practical rules have been deduced from experiment. The following are a few of the more important results thus arrived at: For a given charge and weight of projectile there is a certain length of bore that gives the greatest velocity; the cause being, that with a less length some of the powder is discharged undecomposed, and with a greater the combustion is finished before the ball leaves the muzzle, so that it has to contend with the friction of the gun without receiving additional impulses. Increase of length, accompanied by proportionate increase of charge, gives increased velocity; but the greater velocity is only in proportion to the cube root of the increased length. The resistance of the air does not arise merely from the projectile having to displace its own bulk of it as it advances; for in the case of a body moving with great velocity the air becomes condensed in front of it, while that behind is highly rarefied. The displaced air behind does not return freely to fill up the vacuum, until the speed of the ball is reduced to 1400 feet per second; the maximum profitable velocity is calculated to be 1600 feet, and that, or any higher speed, is believed to be reduced to 1400 feet after a course of 400 feet. The resistance offered to bodies by the air is as their surfaces, i.e., in the case of round or cylindrical shot, as the squares of the diameters; whilst the power of the bodies themselves to overcome resistance is as their weights, or as the cubes of their diameters. Of course balls of like size but different density will produce widely different results. Hence the greater range of solid as compared to hollow shot. Solid shot fired with equal velocities and elevations range as their weight, the heavier overcoming atmospheric resistance better than the lighter. Shot of equal weight and diameter will range according to their velocities; but not in direct proportion, for the retarding power varies as the square of the velocity. Velocities of shot of equal diameter are as the square roots of the charges. The diminution in speed caused by atmospheric resistance may be judged of from the following table of the speed of a 32-pounder at different parts of its course; it being premised that a body in vacuo, once started, should move *ad infinitum*, without decrease of velocity:

	Feet per Second.
Initial velocity	1600
Velocity 500 yards from gun	1126
" 1000 " " "	1000
" 1500 " " "	608
" 2000 " " "	465
" 2500 " " "	367

Action and reaction being always equal and in opposite directions, the explosion of the gunpowder acts with equal force upon the ball and upon the cannon from which it is discharged, the former demonstrating this in its range, and the latter by its recoil. This recoil has to be guarded against as much as possible, either by the weight of the gun itself, or by its secure attachment to a ponderous carriage. The momentum of the recoil, being the product of the shot's weight, and the velocity, is readily calculated. The common charge of a 24-pounder gun being one third the weight of the shot, or 8 pounds, the momentum of both shot and gun will be 1600 (the initial velocity) $\times 24 = 38,400$, which divided by 5600, or the gun's weight in pounds, gives about 7 feet as the velocity per second; if the gun is attached to a carriage, the weight of the carriage must be added to that of the gun for a divisor. The foregoing table exhibits the effects of varying charge and elevation on different kinds of guns. The line of sight of a gun is an imaginary line drawn through the back-sight on the breech and the fore-sight, a notch in the muzzle-ring, or on the first reinforce. The fore-sight is immovable, but the back-sight is so constructed that the notch shall be at a greater or less height above the axis of the gun. When the line of sight is parallel to the axis and horizontal, the discharge is "point-blank;" but when the back-sight is raised, the direction of the axis of the gun will be to a point more elevated than that to which the line of sight is directed. Consequently, by raising the back-sight, a greater elevation, and, ordinarily, a greater range, is given to the piece. In regard to point-blank discharge, Tartaglia established the fundamental proposition that the time occupied by the ball in describing the whole trajectory or path is the same as it would require to fall by gravity from the muzzle to the ground. As regards penetration, it was found by experiments against a martello tower at Eastbourne, with a range of 1832 yards, that solid shot from the 40-pounder Armstrong penetrated into good masonry from 47 to 65 inches, and from an 80-pounder Armstrong 51 to 90 inches. See *Loading*, *Ordnance*, *Projectiles*, and *Windage*.

GUNNY.—A coarse Indian fabric manufactured largely in Bengal. It is of two kinds for artillery purposes in that country, *single* and *double*; the former is used for charcoal-bags, for package of gunpowder-barrels, and as package generally; the latter for slings for carrying shot and shell, and small-arm ammunition-boxes, also for covering ammunition-boxes, making sand-bags, etc. The saleetahs and pin-bags for tents are also made of gunny. The material from which this article is manufactured is the fiber of two plants of the genus Corchorus, i.e., *Corchorus olitarius* and *Corchorus capsularis*; both, but particularly the first-named plant, are very extensively cultivated throughout Lower Bengal. This nature of cloth is universally used for bags of all sorts, and there is a very large exportation of this material to America, the Coromandel and Malabar coasts, and Singapore.

GUNNY-BAGS.—Bags made of coarse gunny-cloth, and used in India with siege-trains for carrying charcoal for the use of the artificers.

GUN OF RESERVE.—The name given to the old French 12-pounder. Its particulars were: bore, $4\frac{3}{4}$ inches; weight, 1350 pounds; charge, $2\frac{1}{5}$ pounds; weight of shell, $25\frac{3}{16}$ pounds.

GUN-PENDULUM.—An instrument invented for measuring the velocity of recoil and muzzle-velocities. It consists of a frame in which a light gun is suspended by means of a rod. The pendulum, of which the gun forms the *bob*, is capable of moving freely when the gun is fired. An arc graduated in degrees and minutes is attached to the frame, by means of which the angle of recoil is registered. Great care is necessary, in adjusting the weights, to get the center of percussion very nearly in the axis of the bore. The use of the gun-pendulum seems to have been suggested by Robins, although Count Rumford first reported, in 1781, the results of various experiments made with it for the determination of the initial velocity of projectiles, and the most advantageous position of the vent. The quantity of motion of the gun as a pendulum is equal to that of the projectile, charge of powder, and the air. From this the velocity of the projectile may be deduced. Extended experiments with both the ballistic and gun pendulums were made in England from 1775 to 1791, by Hutton; at Metz in 1839 and 1840; and in the United States from 1843 to 1848, by Major Mordecai of the Ordnance Department. See *Ballistic Pendulum*.

GUN-PITS.—Excavations made in the earth for the protection of artillery in the field, when a shelter is necessary. The guns may be often protected from the enemy's fire by natural banks, crests of hills, sand-mounds, etc.; but if there be no natural cover, resort must be had to the pickaxe and spade. A gun-pit can be excavated in one hour by experienced men. This gives but a limited space to the gun-detachment; so if there be time the pit can be lengthened, and the thickness of the parapet increased. Since isolated gun-pits, as explained in the first volume of *Instruction in Military Engineering*, would form good marks for the enemy's fire, it would be advisable to connect them by shelter-trenches, in which, however, places should be left to enable the guns to pass readily to the front. Should no natural cover whatever be available for the limber, cover for it and a pair of horses might be provided in a pit, somewhat of the form of a charger-pit, and similar arrangements should be made for the cover of more horses.

GUN-PORTION.—In fortification, half of the merlon on each side of the gun—that is to say, 9 feet on one side of the embrasure and 9 feet on the other.

GUNPOWDER.—Gunpowder is the agent employed in modern warfare to propel projectiles from all guns and small-arms, and generally as the bursting-charge of projectiles; for the explosion of mines; blasting purposes, etc. It is a mechanical mixture giving light, heat, and gas in the combustion or chemical union of its ingredients. Explosion is a phenomenon arising from the sudden enlargement of the volume of a body; as in the case of gunpowder, the solid body is rapidly converted into a gas many times its volume. If the body is confined in a limited space and exploded, great heat is developed and a vast expansion or propelling force produced, the volume of gas being very many times greater than that of the powder. In the United States service, gunpowder is obtained from private manufacturers. It is distinguished by granulation, irregular, as *musket*, *mortar*, *cannon*, and *mammoth*; regular, as *cubical*, and the *molded powders*, i.e., *pellet*, *hexagonal*, and *prismatic* (perforated hexagonal prisms). In all of these the proportions of the ingredients are the same; they differ only in the size and shape of grain, density and details of manufacture. Musket-powder is used for small-arms; mortar for field-guns; cannon for light siege-guns, and the larger-grained and special powders for heavy sea-coast guns. The materials required are *potassium nitrate* (*niter*), *charcoal*, and *sulphur*. They should be of the greatest possible purity to insure excellence of quality and guard against accidents in manufacture. The proportions by weight of the ingredients used in the United States service-powder are $\left\{ \begin{matrix} 75 \\ 76 \end{matrix} \right.$ niter, $\left\{ \begin{matrix} 15 \\ 14 \end{matrix} \right.$ charcoal, 10 sulphur. It is essential to the successful and uniform manufacture of powder that the ingredients should be procured in their rough state, and be refined and prepared for use at the factory; this is also necessary as a security against accidents at the mills. All foreign matter must be carefully excluded, and every precaution taken against their introduction in handling and moving the refined materials.

For the general purposes of artillery, slight variations in the proportions of the ingredients for powder are not found to affect its strength; but for blasting or mining purposes a slower powder is found to answer nearly as well as a quick one, consequently the proportion of niter is reduced much below that of gunpowder. Blasting-powder is thus made cheap; but as it leaves a large amount of residuum, it cannot be advantageously used in fire-arms. The several operations of fabricating gunpowder are: 1st. *Pulverizing;* which consists in reducing the ingredients to finely divided dust. 2d. *Incorporating;* which consists in bringing the particles of this dust into such intimate contact that each particle of powder shall be composed of one of each of the ingredients. 3d. *Compressing;* which gives strength and density to the substance of the powder, by converting the incorporated mixture into a cake which will not crumble in transportation. 4th. *Graining;* which breaks up the cake into small fragments or grains, and increases the surface of combustion. 5th. *Glazing;* which hardens the surface, to protect it from the action of moisture, and rounds the sharp angles of the grains to prevent the formation of dust in transportation. 6th. *Drying;* which frees the powder from the moisture introduced in certain operations of the fabrication. 7th. *Dusting;* which frees it from the dust, which would otherwise fill up the interstices and retard the inflammation of the charge. The proportions of the ingredients, as well as the art of making gunpowder, vary in different countries, and even among the different manufactories of the same country. The variations in the proportions are slight, however, and the differences in the modes of manufacture are principally confined to the more important operations of pulverizing, mixing, and compressing the composition.

The buildings in which the different operations are carried on are separated from each other, and protected by trees or traverses as far as practicable. The saltpeter is usually pulverized sufficiently when it comes from the refinery. The charcoal is placed in large cast-iron barrels with twice its weight of zinc balls. The barrel has several ledges on the interior, and is made to revolve from 20 to 25 times in a minute. It is pulverized in two or three hours. The sulphur is placed in barrels made of thick leather stretched over a wooden frame, with twice its weight of zinc balls from .3 to .5 inch in diameter, and the barrel made to revolve about 20 times per minute. It takes one hour to pulverize the sulphur. The ingredients having been weighed out in the proportions above given, the charcoal and sulphur are put together in a rolling-barrel similar to that in which the sulphur is pulverized, and rolled for one hour. The saltpeter is then added, and rolled for three hours longer. In some mills this operation is omitted. It is now taken to the cylinder, or *rolling-mill*. This consists of two cast-iron cylinders rolling round a horizontal axis in a circular trough of about four feet diameter, with a cast-iron bottom. The cylinders are six feet in diameter, 18 inches thick on the face, and weigh about eight tons each. They are followed by a wooden scraper, which keeps the composition in the center of the trough. A charge of 75 pounds in some mills, and 150 pounds in others, is then spread in the trough of the rolling-mill, and moistened with two to three per cent of water, according to the hygrometric state of the atmosphere. It is rolled slowly at first, and afterward from eight to ten revolutions of the roller per minute, for one hour for 50 pounds, and three hours for 150 pounds of composition. A little water is added, as the process advances, if the composition gets very dry—which is made known by its color. When the materials are thoroughly incorporated, the cake is of a uniform, lively, grayish, dark color. In this state it is called *mill-cake*. The quality of the powder depends much on the thorough incorporation of the materials, and burns more rapidly as this operation is more thoroughly performed.

The mill-cake is next taken to the press-house, to be pressed into a hard cake, is sprinkled with about three per cent of water, and arranged in a series of layers about four inches thick, separated by brass plates. A powerful pressure is brought to bear on the layers, which are subjected to the maximum pressure for about 10 to 15 minutes, when it is removed. Each layer is thus formed into a hard cake about an inch thick. The press-cake must now be converted into the particular size of grain required. And the means employed to break up the press-cake must be so arranged as to crush it up as nearly as possible into the size or sizes of grain wanted, without reducing much of it to dust. The smaller the size of grain, the larger will be the percentage of it obtained from granulated press-cake; hence with the small size of grain formerly used with cannon, any of the older and ruder appliances for effecting granulation gave good percentage of grain. But as recent experiments have conclusively proved that much larger-sized grains should be employed in the larger charges for heavy ordnance, new and improved granulating-machines have been introduced.

The granulated powder as it comes from the machine contains amongst it a large quantity of dust. This is formed by the crushing action of the granulating-machine, and must of course pass through the various sieves and screens with which the machine is provided along with the grain. The grain itself is not in a condition to be made use of as powder, being rough and porous on the surface and very angular in shape; and moreover, the presence of a large quantity of fine dust amongst it would render it not only most inconvenient to handle, but would also render it more liable to absorb moisture, and to deteriorate. A rough, unpolished angular grain would also very speedily rub down into dust, if subjected to much shaking in transport. It becomes necessary, therefore, to free the granulated powder from all traces of dust, and to polish or give a surface to the grains themselves to enable them to bear a great deal of friction without deterioration. Powder is freed from dust by placing it in revolving reels covered with cloth or wire-mesh of various degrees of fineness, through which the dust escapes. It is *glazed* by causing the grains to rub against each other in revolving wooden barrels. The extent to which the operations of dusting and glazing are carried, and the nature of the appliances used, depend entirely on the density, hardness, and size of grain of the powder operated on. Large-grained, dense, hard powder will bear a great deal of knocking about in the reels without becoming disintegrated and forming fresh dust; and will, moreover, bear a great deal of friction in the glazing-barrels, acquiring speedily a high degree of polish. But when operating on a small-grained, soft powder of low density, the dusting must be carefully conducted, as the process will develop as much fresh dust as it removes; and the amount of friction the grains will bear in glazing must be likewise carefully regulated. It is found in practice that powder may be divided into two general classes, each of which requires different treatment in dusting and glazing, viz., the *cannon-powder* of all classes and the *small-arm powder* of all classes. The former is not only pressed to a higher density, but is made of a larger size of grain; the latter generally is of lower density and much smaller size. Modern cannon-powder, being of large-sized grains and of firm consistency, admits of a comparatively open-meshed reel-covering being used in dusting, and of the process being continued as long as required without risk of injury to the grain. The powder can therefore be rendered perfectly free from dust, and sufficiently glazed at the same time, coming out of the reel as finished powder at one operation. Glazing, although of marked advantage to the finer classes of powder, is believed to be highly injurious to varieties approaching mammoth in size, for the reason that through the action of wearing away at one point and building up at another the powder becomes an assemblage made up of nuclei of about the density sought, incased in envelopes of dust, deposited during the period of glazing, and of very materially lower specific gravity than the rest of the mass, although the average or apparent density may be as desired; this causes extreme rapidity of combustion in the outer strata during the first instants of burning, followed by a less rapid development of gas from equal surfaces of the denser center toward the end of that period.

Before powder for the military service is received from the manufacturer, it is inspected and proved. For this purpose at least fifty barrels are thoroughly mixed together. One barrel of this is proved by firing three rounds from a musket, with service-charge, if it be musket-powder; if cannon- or mammoth-powder, from an 8-inch columbiad, with 10 lbs. and a solid shot of 65 lbs. weight and 7.88 inches in diameter; if it be mortar-powder, from a 3-inch rifle-gun, with a charge of 1 lb. of powder and an expanding projectile weighing 10 lbs. The general character of the grain, and its freedom from dust, are noted. Gunpowder should be of an even-sized grain, angular, and irregular in form, without sharp corners, and very hard. When new it should leave no trace of dust when poured on the back of the hand, and when flashed in quantities of ten grains on a copper plate it should leave no bead or foulness. It should give the required initial velocity to the ball, and not more than the maximum pressure on the gun, and should absorb but little moisture from the air. There are five kinds of powder in the United States land-service, depending on the size of the grain, viz.: *mammoth* for the 15-inch gun, *cannon* for smaller sea-coast guns and mortars, *mortar* for field- and siege-cannon, *musket* for rifle-muskets, and *rifle* for pistols.

The size of the grain is tested by standard sieves, made of sheet-brass pierced with round holes. The diameters of the large and small holes are as follows, viz.: for mammoth, .9 inch and .6 inch; for cannon, .31 inch and .27 inch; for mortar, .1 inch and .07 inch; for musket, .06 inch and .035 inch. Not more than 5 per cent. should remain upon the large nor pass through the small standard sieves. The specific gravity of gunpowder must be not less than 1.75; and it is important that it should be determined with accuracy. Alcohol and water saturated with saltpeter have been used for this purpose; but they do not furnish accurate results. Mercury, only, is to be relied upon.

Government powder is packed in barrels of 100 lbs. each. The barrels are made of well-seasoned white oak; and hooped with hickory or cedar hoops, which should be deprived of their bark to render them less liable to be attacked by worms. Barrels made of corrugated tin are undergoing trial, to test their fitness to replace those made of wood. Each barrel is marked on both heads (in white oil-colors, the head painted black), with the number of the barrel, the name of the manufacturer, year of fabrication, and the kind of powder,—*cannon* (used for heavy cannon), *mortar* (used for mortars and field-cannon), or *musket*,—the mean initial velocity, and the pressure per square inch on the pressure-piston. Each time the powder is proved, the initial velocity is marked below the former proofs, and the date of the trial opposite it. In the powder-magazines, the barrels are generally placed on their sides, three tiers high, or four tiers if necessary; small skids should be placed on the floor, and between the several tiers of barrels, in order to steady them; and chocks should be placed at intervals on the lower skids, to prevent the rolling of the barrels. The powder should be separated according to its kind, the place and date of fabrication, and the proof-range. Fixed ammunition, especially for cannon, should not be put in the same magazine with powder in barrels, if it can be avoided. Besides being recorded in the magazine-book, each parcel of powder should be inscribed on a ticket attached to the pile, showing the entries and the issue.

For the preservation of the powder, and of the floors and lining of the magazine, it is of the greatest importance to preserve unobstructed the circulation of the air, under the flooring as well as above. The magazine should be opened and aired in clear, dry weather, when the air outside is colder than that inside the magazine; the ventilators must be kept free: no shrubbery or trees should be allowed to grow so near as to protect the building from the sun. The moisture of a magazine may be absorbed by chloride of calcium, suspended in an open box under the arch, and renewed from time to time; quick-lime, as before observed, is dangerous. The sentinel or guard at a magazine, when it is open, should have no fire-arms; and every one who enters the magazine should take off his shoes, or put socks over them; no sword or cane, or anything which might occasion sparks, should be carried in. Barrels of powder should not be rolled for transportation; they should be carried in hand-barrows, or slings made of rope or leather. In moving powder in the magazine, a cloth or carpet should be spread; all implements used there should be of wood or copper; and the barrels should never be repaired in the magazine. When it is necessary to roll the powder, for its better preservation and to prevent its caking, this should be done with a small quantity at a time, on boards in the magazine yard. In wagons, barrels of powder must be packed in straw, secured in such a manner as not to rub against each other, and the load covered with thick canvas.

The recognition of the fact that different guns require for their most efficient service different powders marks an important epoch in the history of gunpowder. Previous to this time powder was the same, whether it was to be fired in a 6-pounder or 10-inch gun; and though experience showed that the large gun did not resist the strain of the discharge as well as small ones, the difference in their endurance was attributed to other causes than the want of adaptation of the powder to the gun. It was not suspected that the trouble arose from the unsuitableness of the powder. It soon became a recognized fact that the combustion of gunpowder was influenced to a great degree by the size, the shape, and the density of the grain; and as the weight of the projectile to be started became greater, so much greater became the necessity of regulating these particulars in the powder to be used. The improvements which have been made by attention to these particulars have rendered it practicable to use larger guns and heavier projectiles than had been deemed only a few years before to be within the limits of possibility. The point to be attended to is to see that the evolution of gas at the first moment of inflammation is not excessive, and this is effected by reducing the surface of ignition, that is, by increasing the size of the grains. Further, the evolution of gas should be gradual and progressive, and this is accomplished by giving the grain such a density that the hot gas shall not be forced by the pressure through the mass of the grain. The shape of the grain is also a matter of much importance, as influencing the progressive evolution of the gas. That shape of grain must be best which, other things being equal, has at first a small burning-surface and one that is continually increasing; or, this being deemed impracticable, the grain which approximates nearest this ideal must be best. The prismatic-shaped grain, with perforations running through it parallel to the axis of the prism, is to be preferred to all others that have yet been proposed. If it has not thus far given better results than others, it is because the practical difficulties in the manufacture are such as have not yet been overcome satisfactorily; but it by no means follows that they are such as may not, by future improvements, be surmounted.

It is an established fact that the quality of powder made from day to day will vary with the hygrometric state of the atmosphere, and it is almost impossible to make, at different times, two lots of powder which shall be the same in quality. The ingredients, if incorporated with a certain amount of moisture, will produce a different powder from the same materials mixed with a different quantity. Notwithstanding this fact, no efforts have been made to eliminate this source of variation, as it is believed might be done by keeping the air of the incorporating-mill constantly charged at all times with moisture. An important step has been made, however, to avoid this cause of difference more completely in a different way, and that is by the entire exclusion of water in all of the processes of fabrication. The improvement comes from Russia, as did the machine for making the prismatic powder. The materials, after being pulverized and thoroughly incorporated in tumbling-barrels, are raised in temperature up to the melting-point of sulphur at the same time that they are compressed into a cake. They are then cooled while under this pressure. The press-cake is broken into grains and glazed in the usual way. The charcoal has absorbed no moisture, and, as was to be expected, the powder has been proved to be stronger, and, it is said, more uniform in quality than ordinary powder. Should this process develop unknown difficulties and come short of the expectations that have been raised by it, nevertheless it will most likely exercise a beneficial influence on the mode of manufacture by stimulating and directing investigations in a direction that will probably lead to important results in the end. Gunpowder fails in too many respects to come up to the ideal of what the projectile-compound of the present time should be to retain its place much longer, unless marked changes shall be soon made in some of its properties.

English gunpowder has been long held in deservedly high estimation for its strength or explosive force, a quality which has been obtained for it by the exercise of great care in the selection of the best materials, and by the close attention paid to every detail of their preparation and thorough and complete incorporation. The greatest improvements have been made in the quality of the powder since the time when, instead of procuring the supplies required for the military and naval services by contracts with private parties, the Government became the owner of a powder-mill, and the manufacturer of its own powder, or a part of it, the different processes of fabrication being carried on under the immediate direction and supervision of its own agents. This mill is not of sufficient capacity to supply all, or anything like it, of the powder that is required in times of war; but, besides being of the greatest use in keeping up the high standard of the quality of powder (samples of standard powder are furnished annually to all powder-makers of the Kingdom), it is also of value in keeping down the price when supplies have to be procured from private manufacturers. The Royal Gunpowder-factory at Waltham Abbey is situated very near the old church from which it takes its name, about twelve miles from London, on the Eastern Counties Railway. The grounds are the rich meadows on the river Lea, which stream connects the canals between the different mills with the Thames, and furnishes water-transportation to Purfleet, where the powder is stored in large magazines. A portion of the grounds is planted with willows, set out with great order and neatness, the wood to be used for making charcoal for powder. The buildings in which the different processes of fabrication are carried on are scattered over upward of fifty acres, and built with special reference to the purposes for which they are intended. The niter and sulphur used are procured in the crude state and refined at the factory. This course is pursued in preference to purchasing them already refined, with a view of insuring uniform results in the powder manufactured, and of guarding more effectually against accidents, so much to be dreaded, from the presence of certain foreign particles in the materials, introduced among them before they reach the mills.

The grough saltpeter of India is purchased to the exclusion of all others. The process of refining is the usual one, and has in it nothing calling for remark. The water used is from an artesian well, and is remarkably pure and free from all mineral substances. The sulphur is procured from Sicily, and contains from 3 to 4 per cent of earthy matter, from which it is purified by distillation. It is ground under a small pair of wheels, when it is ready for mixing. Willow and alder are the woods used for making charcoal for all powders except musket. For this latter the alder buckthorn, or the berry-bearing alder (*Rhamnus frangula*), commonly known as the black dog-wood among powder-makers, is exclusively used. All of these woods grow in different parts of England, and efforts have been made to cultivate them on the grounds of the powder-mill, with success as regards the first two, but not the last, which requires a poor and rocky soil instead of a rich meadow-land for its growth. Large quantities of the dogwood are stored away for future use at the factory; the sticks, of about one inch in diameter, all brought from Prussia, at a cost of from $60 to $75 per ton. The difference between this and all of the other woods commonly regarded as best adapted for making powder is most marked, all of the others being light, brittle woods of rapid growth, whereas this is a dense, tough wood of slow growth, requiring usually ten years to attain a size of one inch in diameter. The charcoal is prepared by distillation in cast-iron retorts of cylindrical shape, set in brick-work, with flues to conduct the flame all round them. The gaseous matter and tar evolved in the distillation is conducted by pipes into the fire, and, besides economizing fuel in preparing the charcoal, furnishes the readiest means, by the color with which they burn, of determining when the charcoal has been carried to the proper point.

For convenience in handling, the wood is first put in sheet-iron cylinders, which are placed in the retorts. The retorts being thoroughly heated, the operation of charring requires from 2½ to 3½ hours. As the quality of the powder depends greatly on the temperature at which the charcoal is prepared, great care is taken to have this temperature constant and sufficiently high, but not too high. This is indicated by the color and fracture of the coal, which should be a jet black, with a clear velvet-like look when freshly broken. Analysis confirms the practical experience of powder-makers, that dogwood-charcoal makes a stronger powder than coal of any other wood, containing as it does a greater amount of gaseous constituents. The charcoal is ground in a mill resembling an ordinary coffee-mill, and is sifted by passing it into a cylindrical frame covered with iron-wire cloth, 32 meshes to the inch, and having a rotary motion around its longer and horizontal axis. The proportions of these ingredients are the same as those used in this country. They are weighed out in the proper proportions for a 50-pound charge, the saltpeter containing from 3 to 6 per cent of moisture, and are mixed together in the mixing-machine. This consists of a hollow bronze drum, which makes 40 revolutions per minute. A shaft passes through the axis of the drum, having a large number of arms made fast to it. The shaft and arms revolve in the opposite direction to the drum, and at twice its speed, thus mixing the ingredients together. The thorough incorporation of the materials is effected under heavy cast-iron or stone wheels, as in this country. The wheels are of various sizes, some as large as 7 feet in diameter, and others only one half of this, the preference being given to the smaller, as they are not so apt to cause explosions. The weight varies from 3½ to 4 tons. The bed is about 7 feet in diameter. There are in all 32 pairs of wheels for incorporating. A portion of them are driven by water-power, others by steam. The time required for the incorporation of a charge depends upon the kind of powder, the weight of the wheel used, and its velocity. Cannon-powder requires from 2½ to 3½ hours; musket-powder from 4 to 5½ hours. For the convenience of applying the motive power, the wheel-mills are placed in groups of four or six; and to prevent the explosion of one from extending to others of the same group, each is provided with a large vessel of water overhead, so arranged that an explosion of either mill of the group will overturn all of these vessels and pour the contents into the mill-bed beneath. This apparatus has been found to answer a good purpose, and has saved at different times a large amount of property.

Before being taken to the press-room to be pressed into cake, the mill-cake is passed through the breaking-down machine, which breaks up the lumps into a fine state of division to facilitate the operation of pressing. The breaking-down machine consists of a pair of gun-metal, cylindrical rollers, grooved longitudinally. They are placed side by side, their axes parallel and horizontal. The bearings of one roller are not fixed, but can be moved to or from the other, and are held in their proper position by means of a weight. The two rollers revolve in opposite directions, and the powder passing between them, the cakes and lumps are broken up into fine meal. A second set of rollers like those just described are placed directly under them, and break up any lumps that may have escaped the action of the first pair. The powder to be broken up is placed in a large hopper, from which it is carried to the rollers by an endless belt of strong canvas, which passes through an opening at the bottom of the hopper to the top of the machine, where it falls between the first pair of rollers.

The press used for pressing powder into thin cakes is operated by water pumped into a vertical cylinder. The press-box, in which the powder is placed, is 30 inches by 14 inches inside, made of great strength, of bronze, lined on the inside and outside with oak boards. Three sides of the box are hinged to the bottom, and when closed are secured by short, strong bronze screws. In order to charge the box the open top is temporarily covered with a piece of board, and the boxes turned over on one side. Bronze racks, with vertical grooves in them 1½ inches apart to hold the press-plates, are placed against two opposite sides, and the plates, 48 in number, slipped in. The spaces between the plates are filled with powder thrown in with a shovel, and the racks are then withdrawn, leaving the powder in layers 1½ inches thick, with a plate between the consecutive layers. The side which is now on top is screwed fast, and the box is turned over onto the table of the hydraulic press, bringing the press-plates horizontal. The board cover is removed, and the solid wooden block overhead, which resists the pressure of the ram, is adjusted so as to enter the box and be forced deeper and deeper into it as the powder is compacted. The pressure is applied by pumps driven by water-power in another building, between which and the press-house there are large earthen traverses. The inspection of powder is conducted with a strictness that would surprise our powder-makers. An inspection is required of the pressed cake after each pressing, and its density is determined with the mercury densimeter before it is permitted to pass on to the succeeding processes. The density of musket-powder is fixed about 1.725, and that of pebble-powder from 1.77 to 1.81, and R. L. G. 1.67. The finished product of each day's labor is inspected and proved. The size and shape of the grain are accurately determined. The proof of the different kinds of powder consists in determining the velocity imparted to a projectile fired from a gun under circumstances as nearly similar as possible to those of actual service. Musket-powder must give the service-ball a certain velocity when fired from the regulation musket; cannon-powder is in like manner proved by testing its strength when fired in the 12-pounder rifled gun; and pebble-powder when fired in a 9-inch or large gun.

In Russia all powder used in the military and naval services, as well as most of that for sporting and mining, is made under the direction of the Government at its own factories. Of private mills there are only a few small ones in Finland, where powder for sporting and mining purposes is made. The Government mills are three in number, and are situated in different parts of the Empire: 1. The Ohktenskoi mills, near St. Petersburg. 2. The Michael-Schosta, in Little Russia, in the saltpeter district. 3. That in the Kazan. Of these the second is the most extensive; the first is provided with the newest machinery and most improved appliances, and has a great capacity. The Ohktenskoi mills are situated on the Ohkta River, about six miles from St. Petersburg. They occupy about 1½ square miles of land, 230 acres of which, where the dangerous operations are performed, being inclosed by a high picket-fence on three sides, and the river on the fourth. The river furnishes the greater part of the power required for running the mills, but their number has been from time to time increased until the capacity of the stream has been exceeded, and now horses and steam have to be employed in addition to the water-power. The buildings are substantially constructed of brick on three sides, the fourth being of wood, so as to yield readily to any explosive force from within. The side selected for this purpose is that which is in the opposite direction from those buildings nearest to it. The buildings most recently erected, besides being built more solidly, are surrounded on three sides by an embankment of earth 15 feet high, 40 feet broad at the base, and 12 feet at the top. It has been found by experience that the vibrations resulting from an explosion are broken most effectually, and contiguous buildings are injured less when a body of water is interposed between them and the place of the explosion. For this reason a canal or pond of water is dug between the mills most liable to be exploded and the houses nearest to them. The grounds vary considerably in level, and the communication between the different mills is principally by means of wheelbarrows, very little by boat, and none by railway-trucks. The motive power furnished by the river is well applied. Just below the dam two large iron tubes 200 yards long and 4 feet in diameter, resting upon iron rollers raised on brick piers 6 feet above the surface of the ground, conduct each a stream of water to a series of eight water-wheels placed between a double row of wheel-mills, so that each water-wheel communicates motion to two mills. Some of these water-wheels are overshot, of 12 horse-power, and made of wood; but those most recently put in are of iron and of a peculiar construction. The water enters through a vertical pipe into the interior of the wheel to within about 2 feet of the bottom, and is then discharged from the curved surfaces which form the exterior. It is said to have a coefficient of .8. The rollers under the iron pipe are for the purpose of enabling it to accommodate itself readily to the changes in its length caused by the expansion and contraction due to the variations of temperature to which it is exposed; and this is considerable, between three and four inches.

The proportions of the materials used in the manufacture of gunpowder in Russia are the same as those used in this country and England. The saltpeter is obtained partly from Little Russia, where it occurs as a natural efflorescence on the ground, and may be much hastened by scraping the surface; and partly from the banks of the Volga, where there are found vast mounds, manure-heaps, which are now so many mines of saltpeter. So far from Russia being dependent upon any other country for this all-important material in times of war, she has within her own territory a larger supply than is necessary for her own wants, and is able to export some to Austria. Supplies required for the manufacture of gunpowder are furnished at the mills by contractors, already refined and ready for immediate use. The sulphur is obtained from Sicily in the state of roll-sulphur, which is further purified by distillation in the usual way. The charcoal was formerly made from the alder, but it is now made from a variety of the birch. Young trees as large as 5 or 6 inches in diameter are used. It is prepared in the usual way by distillation in iron cylinders in charges of 144 lbs. Fuel being abundant, no effort has been made to economize it by consuming the gaseous products of the distillation of the wood, as is done in England and Prussia. The charcoal and sulphur are pulverized together in a metal barrel 3½ feet long and the same in diameter. Three parts of charcoal and two parts of sulphur are put into the barrel with bronze balls ⅜ inch in diameter. The barrels are set in motion by horse-power, and made to revolve until the materials are reduced to a fine powder and thoroughly mixed together. The balls are separated from the mixture by means of a coarse sieve through which it is made to pass. One part of this composition is added to three parts of saltpeter, and the whole is thoroughly mixed together by hand on a table with raised sides and covered with a cotton cloth having holes in it to admit the arms of the workman. A little water is first added. This composition is next put, in charges of 120 lbs., under the wheels to be ground for four hours. The wheel-mills are of different construction, depending on the date at which they were put in. Those first used are of bronze, with bronze beds, about 4½ feet in diameter, and weigh about 3½ tons each. Those more recently put in are of iron, with iron beds about 7 feet in diameter, and weighing 4½ tons each. Some pairs of wheels revolve around an axis equidistant from the two wheels; in other mills the two wheels travel over tracks of unequal length. The results of a long experience show that there is no advantage to be had in making the wheels or bed of bronze; that such mills are no more exempt from explosions than the cast-iron mills, and in consequence the use of the costly material in future constructions is relinquished. The particular arrangement and disposition of the buildings for the incorporating-mills adopted at this establishment, by which they are placed in double parallel rows, with a water-wheel between each pair, the buildings being brought so close together, is most convenient and economical in supplying power to the different mills, but is highly objectionable in tending to render the explosions more destructive by increasing the chances of the explosion of one mill communicating to others.

The powder, as it leaves the incorporating-mills, or mill-cake, as it is termed, is broken into pieces by hand with wooden mallets and is passed to the press-house to be formed into cake. This is done by two different varieties of presses, the hydraulic and the Prussian press. The density of the Russian powder, like that of the Prussian, is very low, cannon-powder being .940, and musket from .920 to .935. The granulation of the powder is also performed in machines of quite different construction. One is the same as that used in Germany; the other consists of a long bed in which are arranged several series of sieves, each series consisting of four sieves, which are placed one over the other, the coarsest at the top. To this bed containing the sieves a quick horizontal reciprocating motion is communicated by machinery. The press-cake is placed in the upper sieve, and with it hardened lead balls about one inch in diameter. The balls now impinging against the cake, break it into pieces, the operation being continued until the pieces have been reduced in size so that they will pass through the meshes into the sieve beneath. The smaller pieces pass through the sieves until they have been assorted according to sizes of the meshes, the dust falling into a trough under the sieves. The contents of the sieves are put away arranged according to the size of the grain, and the dust found in the trough is taken back to be worked over. The glazing is done in the usual way by the friction of the grains against each other in revolving barrels. It is next dusted, and the grains are again assorted. The operation of dusting is different from that generally seen in other mills, though it is believed that its novelty is its only claim entitling it to notice. The machine consists of a horizontal wooden frame, with vertical guides to direct its motion up and down. On the under side of this frame there are pins driven in, from each of which is suspended by its closed end a long narrow bag of coarse linen cloth, something like a shirt-sleeve. The lower and open end of the bag is drawn aside from its vertical position, distended, and made fast to a wooden partition close by. Holes of the size of the mouth of the bag are cut into this partition where the bags are fastened to it, and are closed by snugly-fitting trap-doors which are secured from the outside. The powder is introduced into the bags through these holes until they are less than half full, and the holes closed; a vertical reciprocating motion is now communicated by machinery to the horizontal frame from which the bags are suspended, extending the bag each time its full length, bringing the closed end first above and then below the fixed end, and causing the powder to traverse back and forth from one end to the other and by its gentle motion to sift the dust through the cloth, when it falls to the floor beneath. Prismatic powder is made by compressing a given charge of soft grain-powder, which contains from 5 to 6 per cent of moisture, in a strong mold of the required size. The holes in the prism are formed at the same time the prism is made by means of small tapered spindles, which pass through the powder and the compressing-punches. The only machine that has been devised for the manufacture of this powder is the one designed by Professor Vichnegradski, and made in Russia, and since copied in Prussia and Holland. The idea of using powder compressed into a solid cake with parallel holes running through it forming surfaces of combustion which shall be continually increasing as the combustion continues was borrowed, as the Russians themselves frankly admit, from some experiments made first by Captain Rodman at Fort Monroe in 1861, and witnessed by a distinguished artillery officer of the Russian army. The idea was carried out successfully in a practical form first by the invention and operation of this machine, which is essentially one strong vertical punch carrying six punches, and forming six prisms or grains of powder at each revolution of the shaft or the descent of the punches. It is widely different in its general design and working from the machine made in England for pressing the grains of pellet-powder, as well as more successful and economical.

From the machine the prisms are next taken to the drying-house, where they are kept for a month; or, when the weather is good, they are dried in the open air, that is, in a building provided with numerous doors and windows which are kept open, but without the aid of artificial heat. Here they will dry in the course of five weeks. The density of prisms varies from 1.65 to 1.75, according to the gun in which it is to be used; the latter density is for the 11-inch gun. Prismatic powder is not glazed; it is said to resist the action of moisture better than ordinary powder. It is packed in boxes lined with paper, the prisms laid on their bases, close together, so they cannot move, and covered with felt. This kind of powder is not made at either of the other mills. In filling cartridges with prismatic powder, pains is taken to pack the prisms in the bag laid on their bases, fitting as closely as they can be packed, the holes in the prisms corresponding with those above and below, and forming air-passages for the communication of the flame through the whole length of the cartridge. The cartridge-bag is tied closely over the powder, fitting it snugly, and keeping the prisms in their places. Prismatic powder is used exclusively for all guns of a caliber of 8 inches and over. For 6-inch guns it is sometimes used, but not invariably, ordinary cannon-powder being also occasionally used, though less frequently than the prismatic. Ordinary cannon-powder is used for all field-guns and those of less caliber than 6 inches. All powder is proved by firing service-charges and determining the initial velocity of the ball. Ordinary cannon-powder is proved in a 4-pounder gun, the prismatic in an 8-inch gun. The pressure exerted on the bore of the gun by the prismatic powder is also determined.

Gunpowder for the Prussian military service is made part at the Royal Powder-mills of Spandau and Neisse, and part by private manufacturers in different parts of the Empire, the standard of quality being regulated by the former. The powder-works at Spandau are of very ancient date, a pounding-mill having been established here as early as the year 1344. They are situated on low ground on the banks of the Spree, in the midst of a wood only a short distance from the Arsenal on the opposite side of the river. The buildings, mainly of wood, are placed at considerable distances from each other, and the roads leading from one to another are covered with tan-bark to avoid the introduction of sand or gravel into the buildings, carried on the feet of the workmen. Water-power is the motor used to drive the machinery, with the exception of one steam-engine which drives the fan for forcing hot air into the drying-house some distance off, the boiler furnishing the means of heating the air. Few changes have been made in the manner of making powder within the last fifty years or more. The method of incorporating the materials known as the "revolutionary process," from its having been adopted during the war of the French Revolution, though given up by every other nation, has been adhered to with only slight modifications. By this method the materials are pulverized and incorporated by being rolled in barrels turning on horizontal axes, and containing besides a quantity of bronze balls of small size. The composition is pressed into cake by means of two rollers between which it is made to pass, being first evenly distributed on an endless band of coarse linen. The upper roller is of bronze, and its pressure on the lower roller is increased and regulated by a weighted lever. The woods used for making the charcoal are the berry-bearing alder and willow, which are cut into lengths of about one foot, from branches about an inch in diameter. The distillation is conducted in cylindrical iron retorts into which the wood is closely packed and then sealed. The retorts are provided with small wheels for the convenience of running them in and out of the furnaces.

After glazing, the powder is dried at a temperature of 190° F., being laid out for the purpose on thin canvas stretched over hot-water pipes, the hot air being forced up through the powder by means of a fan-blower. One hour and a half is sufficient to dry it. Its specific gravity is 1.64. The process of manufacture of prismatic powder was obtained by Prussia from Russia. The prisms are 1 inch thick, and the diameter of the circumscribing circle is 1.57 inch. There are seven holes, one in the center and the others opposite the angles, the center .32 inch distant from the angle. The holes are tapering from .185 inch to .165 inch. Specific gravity 1.66. A prism weighs 587 grains. They are packed in boxes of 110 pounds each. To prevent the prisms from breaking, a piece of felt .4 inch thick is placed on top of the prisms and at the end of the box. Prismatic powder is used in the 15-centimeter and all larger guns. The powder used by Krupp in all of his large guns is of the prismatic form, made at Hamm, by a private manufacturer, after the Russian system. The size of the prisms is the same as used by Russia and Prussia, the density varying with the caliber of the gun in which it is to be used. For the 12-inch and 14-inch guns the prisms are perforated each by only a single hole instead of seven, and that is in the center; it is .59 inch in diameter. The specific gravity is from 1.73 to 1.76. Important changes have been made in France during the last decade in the manufacture of gunpowder. The separate department for the management of the powder-mills and saltpeter-refineries has been abolished. The greater number of these establishments which were engaged in making sporting and mining powders has passed under the direction of the Minister of Finance; and five—Ripault, Bouchet, Saint Chamas, Angoulême, and Esquerdes—have been reserved for the manufacture of gunpowder for the Army and Navy. Since 1865, the date of this change, all experiments on cannon-powder have been carried on exclusively by officers detailed for the purpose. The powder-mill of Bouchet has been completely under the orders of the marine in making experimental powders for large guns. Numerous and different powders, varying in the proportions of the ingredients, the mode and time of mixing, the density, size, and shape of grain, have been made and sent to Gâvre or Ruelle, to be fired from guns of proper size, and the effects on the projectile and the gun carefully noted. Similar trials have been made with foreign powders, such as the English pellet, the Russian and Dutch prismatic, the Wetteren large-grain, and powders made like them, and their effects carefully compared.

Of all the powders experimented on, that which has given the best results in large guns is the large-grained powder made at the Royal Powder-mills of Wetteren, in Belgium. The pounding-mills, with their mortars and pestles, which have been so long used for incorporating the materials of gunpowder, have at last given place to the wheel-mill, in spite of the objections made to its use. It was found to be impossible to make powder suitable for the new material by this process, and a change has been also made in the proportions of the ingredients, and the formula used by most other nations has been adopted. France has acted to a greater extent than any other Power on the principle that every gun has its particular powder, which will do in this gun more work than any other, and has accordingly prescribed the size of grain for the powder to be used in each of the large calibers. The sizes adopted are, for the 14-centimeter gun, between .275 inch and .3937 inch; 19-and 24-centimeter gun, between .51 inch and .63 inch; 27-centimeter gun, between .63 inch and .787 inch. The Commanding Officer of the Bouchet powder-mill was charged with the duty of getting up a powder which should give as favorable results in large guns as that procured from Wetteren. Following the process suggested by Captain Castan, the effort was entirely successful, as was shown by the satisfactory report made on it by the Commission at Gâvre, where it was tested. The form given to the grain is that of a flat parallelopipedon, the thickness of which is the same as that of the pressed cake. A large-grain powder has also been made, suitable for the field-artillery, and another for siege-guns. The latter has grains .43 inch thick and a density of 1.79. It gives as high a velocity as the compressed rings previously used, with a less pressure on the bore of the gun.

Austria obtains her supply of powder partly from mills belonging to the Government, and partly from private contractors. Numerous experiments have been made with prismatic powder with the usual favorable results, but the expense of manufacture led to the search by experiment for a less costly powder which should meet the requirements of the service. In 1873 trials were made with a pebble-powder of an English make, and samples made at Stein, with grains of different sizes and density. The results showed the practicability of varying the grain in size and density so as to produce a powder which shall give in the gun for which it was intended sufficient ballistic effects with little fatigue to the gun. The experiments have not yet been concluded. Trials have been made with the Castan powder with good results. All of the dense powders thus far tried have given, with velocities equal to those given by the prismatic powder, considerably less strain on the gun. These powders have a specific gravity of 1.759 to 1.785. The proportions of the constituents used are 74, 10, 16, and the incorporation is effected by means of the wheel-mill. See *Absolute Force of Gunpowder, Breaking-down Machine, Charcoal, Compensating Powder, Cubical Powder, Densimeter, Drying store, Dusting-reels, Explosion, Explosive Agents, Glazing-machine, Granulating-machine, Gun-cotton, Hexagonal Powder, Incorporating-mill, Inspection of Powder, Magazine, Mammoth Powder, Mixing-machine, Nitrate of Soda, Nitro-glycerine, Packing of Powder, Pebble-powder, Pellet-powder, Powder-press, Preservation, Prismatic Powder, Progressive Powder, Round Powder, Saltpeter, Schaghticoke Powder, Schultze Powder, Sifting reel, Special Powders, Sphero-hexagonal Powder, Square Powder, Storage and Transportation of Powder, Sulphur, Wetteren Powder*, and *Wiener Powder*.

GUNPOWDER-BAGS.—Bags made of serge or other cloth, and used for blowing open gates, stockades, etc. The size of the bags differs according to the charge intended to be placed in them; they are fired generally by means of a Bickford fuse. The bags are either placed on the ground or fastened by a hook to the gate. In Burmah, in 1852, experiments were made to test the value of powder bags in blowing down stockades, and the result proved most satisfactory; bags containing about fifty pounds of powder causing a rent large enough to admit of a section of infantry entering within the inclosure. Experiments were also at the same time made with 8-inch howitzers, which failed to make much impression on this manner of defense. The Indian water-carriers' *mussuck* (water-bag), can be used as a powder-bag in any emergency.

GUNPOWDER FACTORY.—A series of buildings in which the several processes in the manufacture of gunpowder are carried out. A gunpowder-factory should be situated far away from inhabited localities. The buildings should be made of wood, so that in case of explosion the smallest resistance would be offered to the force of the powder. Explosions under any circumstances are disastrous, but if they occur in a masonry building are still more so. The generality of mill-houses, therefore, will be found to be made of wood, and protected from one another by huge banks of earth or thick masonry surrounding each house. There is no objection to making incorporating-houses of masonry if the walls are built thick enough to withstand the explosive force of a "mill-charge" (fifty pounds). To add to the safety of incorporating-houses, in case of an explosion in one room, the charges in the other rooms are by means of self-acting machinery instantaneously drowned in the water.

The principal, indeed the only, Government factory for the manufacture of gunpowder in England is at Waltham Abbey. All powder required in excess of what this factory is able to turn out is supplied by private factories on contract. In India there are three factories, one in each Presidency. See *Royal Gunpowder-factory*.

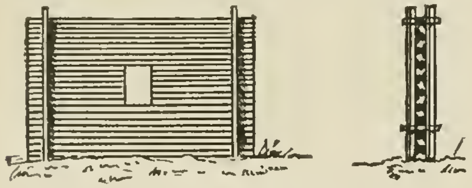
GUNPOWDER-HAMMER.—The pile-driver operated by the explosive force of gunpowder. Strong efforts have been made to bring this machine to successful operation, but in consequence of the great expense of working, the constant care, and the very accurate adjustment required, it has fallen into general disuse, especially for military purposes. The machine in its improved form may be described as follows: The leaders are built of iron and very carefully aligned. The "gun," shaped somewhat like a short field-piece, with wings on either side, and a recess at the breech, is fitted by means of grooves in the wings to slide easily between the leaders, the recess or cap receiving the head of the pile to be driven. When in position for driving a pile, the ram is suspended at the top of the leaders, held there by a trip operated by a line in the hands of a man on the deck of the machine. From the lower face of this suspended ram is a shaft turned to accurately fit the bore of the gun, whose upturned muzzle is expected to receive it. At a suitable height to accommodate the operator is an adjustable platform, which carries the operator and his supply of cartridges, containing each usually about three ounces of powder. When it is desired to drive a pile, the operator, standing on his platform, drops a cartridge into the muzzle of the "gun" and trips the suspended ram, whose projecting pintle, entering the muzzle of the "gun," by compressing the air generates the degree of heat necessary to explode the cartridge, the explosion of which throws up the hammer, and at the same time projects the pile into the ground. As the hammer or ram is thrown up, the alert operator drops in other cartridges, which are in turn exploded by the returning ram. As the pile settles into the ground, assistants keep the platform occupied by the operator in proper position; and when it is desired to stop the driving, enough cartridges are dropped into the gun to produce an explosion that will send the hammer clear to the top of the leaders, where it is caught and held ready for the next pile, which is brought into position in the usual manner and by the use of the ordinary machinery, which also twists the gun and lowers the same on to the head of the pile. In practice, to drive a 12-inch pile twenty feet into firm clay about two hundred blows would be struck, at an expense for powder of between three and four dollars. The gun is found to soon become foul, and creases are soon cut in it so that an escape of air causes the failure in exploding a charge: in which case a jamming of the pintle in the bore of the "gun" results, causing a great delay and no little expense. In Shaw's pile-driver, the monkey, or ram, is sustained at its highest elevation by means of a ratchet and pawl, while a cartridge and cap are placed in a recess in the head of the pile. The pawl being withdrawn, the monkey falls upon and explodes the cartridge. The force of the explosion raises the monkey to the height from which it fell, where it is automatically arrested by the detent arrangement. The effective force of the fall is said to be much increased by the action of the powder. One man places the cartridge in position and releases the ram. See *Pile-driver.*

GUNPOWDER-LAWS.—In order to guard against the frightful consequences to the public likely to arise from carelessness in the preparation, preservation, or conveyance of this most dangerous article, the English Legislature in 1875 made stringent rules upon the subject. By an Act which applies also to Scotland and Ireland it is provided that no gunpowder shall be manufactured except at a factory lawfully existing or licensed under the Act, and it shall not be kept except in the factory where it is made, or in a magazine or store duly licensed, or in registered premises. The license is obtained from the local authority (usually Justices), and approved by the Home Secretary. General rules are imposed for regulating factories and magazines. There must be a lightning-conductor. No charcoal nor oiled rags must be taken into the building except for immediate use. No smoking is allowed. Tools are to be made of wood or soft material. Workingmen's clothes are to be without pockets. Carriages and boats for conveying gunpowder must have in their interior no iron or steel exposed. Each building is to have affixed, so as to be easily read, the quantity of gunpowder allowed in each. Retail dealers must be registered, and must keep their powder in a separate house or in a fire-proof safe, not exceeding 200 lbs.; but if kept inside the dwelling-house, 50 lbs., or if in a safe inside, 100 lbs. The building or safe is to have no exposed iron or steel in the interior. A breach of precautions against fire or explosion is visited with heavy penalties. The local authorities must keep registers of licensed persons, and all rate-payers can demand a copy thereof. Retail dealers, if using less than 5 lbs. for cartridges at one time, are exempted from taking out a factory-license. No powder must be sold to a child under 13. All powder exceeding 1 lb. weight must be sold in a canister or case securely fitted, and with the word "gunpowder" visible. Also, powder must be closely and securely packed and labeled for conveyance, if exceeding 5 lbs., and the amount carried is not to exceed 100 lbs. All Railway and Canal Companies are to make rules and have special times and places for loading and unloading powder. Fire-work factories, if making and keeping less than 500 lbs of fire-works, need only a license from the local authority; but exceeding that quantity, one from the Home Secretary. To let off a fire-work in a street or highway subjects the offender to £5 penalty. A Government Inspector may at any hour of day or night enter and inspect any factory, magazine, or registered premises, and may require the occupier, under a heavy penalty, to make alterations or take certain precautions. Search-warrants are also readily granted, and in urgent cases are dispensed with.

GUNPOWDER MILL.—A machine used for mixing or incorporating the ingredients of which gunpowder is composed. The operation was formerly effected as follows: The ingredients being duly proportioned and put into the mortars of the mills, which are hollow pieces of wood, each capable of holding 20 pounds of paste, are incorporated by means of the pestle and spindle. There are 24 mortars in each mill, where are made each day 480 pounds of gunpowder, care being taken to sprinkle the ingredients in the mortars with water from time to time, lest they should take fire. The pestle is a piece of wood 10 feet high and 4½ inches broad, armed at the bottom with a round piece of metal. It weighs about 60 pounds. For more modern methods of incorporation, see the article *Gunpowder.*

GUNPOWDER PLOT.—A fanatical project on the part of a few Roman Catholics to destroy the King, Lords, and Commons on the meeting of Parliament on November the 5th, 1605. James I. had succeeded Elizabeth two years before, and his Government had exercised great severities against the Roman Catholics, not merely denying them religious toleration, but confiscating their property. A few ruined and exasperated men banded together to overthrow the Government. The originator of the plot was Robert Catesby, a man of fortune, which he had impaired by youthful extravagance, and who communicated his idea to Thomas Winter, who was horrified at first, but after a while began to approve and further it. For this end he enlisted into the conspiracy Guy Fawkes, a soldier of fortune, of considerable military experience, and a most determined and fearless character. Catesby enlisted other two, by name Wright and Percy—the latter a relation of the Earl of Northumberland. They hired a house and garden contiguous to the Parliament House, and commenced their mine, a part working when the others slept, and the rubbish being buried during night. One day they were alarmed by a noise after they had with much labor pierced the wall three yards thick. Fawkes learned that this noise proceeded from a cellar under the House of Lords, which would soon be vacant. He hired it, and barrels of gunpowder were placed in it, and stones and billets of wood placed over them, for the double purpose of concealment and to act as destructive missiles when the gunpowder was fired. In the interval, a brother of Wright and a brother of Winter had been added to the conspirators, so they were now seven. But they wanted money; and to supply it, two others were induced to enter this fanatical copartnery, and these were Sir Everard Digby of Gatehurst, in Buckinghamshire, a young gentleman of large estates; and Francis Tresham, a follower of Essex, like Catesby and Percy, but, unlike them, a selfish unenthusiastic man. Their plan was finally arranged for the reassembling of Parliament, which was to take place on the 5th of November. Guy Fawkes was to fire the mine (if the gunpowder in the cellar may be so called), and then flee to Flanders by a ship provided with Tresham's money, and waiting ready on the Thames. All the Roman Catholic Peers and others whom it was expedient to preserve were to be prevented from going to the Parliament House, by some pretended message or other, on the morning of that day. After all was ready, Lord Mounteagle was at supper at his country-house at Hoxton, where he very seldom was. As he sat, a page handed him a letter received from a stranger, advising him "to devise some excuse to shift off your attendance at this Parliament, for God and man hath concurred to punish the wickedness of this time." That this letter was written by or for Tresham, who was the Lord Mounteagle's brother-in-law, there can be little doubt. That he desired to save him was certainly one reason for writing it; that he desired to save the conspirators, or at least to allow them to escape, is very probable; and that they might have escaped, but for the fanatical hopes of Catesby, is all but certain. It is also probable that Lord Mounteagle had been fully informed of the whole matter by Tresham, and that the supper in the country and the letter were mere devices to conceal Tresham's treachery. When the letter was formally communicated to the King, he at once declared its meaning, and the most simple way of accounting for his power of divination is to suppose that, like Lord Mounteagle, he had been told beforehand. On the very evening of the 4th, the Lord Chamberlain and Lord Mounteagle visited the Parliament House, and entering the cellar in a casual way, told Guy Fawkes, whom they found there, and who passed as Percy's servant, that his master had laid in a plenty of fuel. Only fanaticism gone the length of fatuity could have made him persevere after this. But he did, though escape was still possible; and on the morning of the 5th, a little after midnight, he was arrested coming out of the cellar, dressed as for a journey. Three matches were found on him, a dark-lantern burning in a corner within, and a hogshead and thirty-six barrels of gunpowder. He was examined and tortured. He confessed his own guilt, but would not discover his associates. However, he and the chief of them were either killed on being captured, or died on the scaffold; except Tresham, who at first walked about openly, but at last was apprehended, and died of a natural disease in the Tower. The memory of this plot, invested by much fiction, has survived in England; and it was not more diabolical than hopeless and mad. It was in itself mysterious, and for purposes of state policy and Protestant zeal a further mystery was thrown over it. No name in English history has been more detested than that of Guy Fawkes.

GUN-SHELTERS.—During the third period of siege-operations the musketry-fire of the besiegers becomes very destructive to the artillerists of the defenses whilst serving the guns. Strong iron or oak musket-proof blinds should be arranged to mask the mouths of the embrasures when the guns are not in battery. Blinds, or covers of timber and of earth under which



guns can be secured from projectiles that would reach them at top or in flank, will now be serviceable. A few guns covered in this way, and placed in the salients of the collateral works, to obtain reverse views on the trenches constructed on the glacis of the works, will prove a serious annoyance to the sappers, and will greatly retard their progress. When railroad-iron can be obtained, shields, with embrasures in them, can be made as represented in the drawing. One thickness of iron is sufficient protection against projectiles from field-guns, two from siege-guns, and four from pieces of the 8-inch rifle class. The same material may be used for constructing field-casemates. See *Mantlet*.

GUN-SHOT.—The distance of the point-blank range of a cannon-shot. The distance to which shot can be thrown from a gun so as to be effective. The term *gun-reach* is used in the same sense.

GUN-SHOT WOUNDS.—These wounds may vary in severity from a simple bruise to the tearing away of a whole limb. Single balls produce a cut, bruised or lacerated wound, according to the amount of their velocity when they strike the body. The effects of small shot vary with the distance and power of the gun; when close, the charge enters with the pellets so close together as to make one wound like a single ball. Some years ago it was commonly believed that the "wind of a large shot" could produce serious injuries: this belief may have arisen from the circumstance that when a heavy ball, which has lost some of its force, strikes the body at a particular angle, the skin does not always give way, but the deeper structures, such as the muscles, or the large organs, as the liver, may be completely crushed. If the wind of a shot could kill a man, it is not likely that soldiers should have had ears, noses, and lips shot off and yet have experienced only the symptoms produced by those slight injuries.

When a bullet passes out of the body, there are two openings—that of "entrance," which is generally depressed, round, regular, and smaller than that of "exit." The modern conical ball makes a well-defined oblong wound, but it may shift its direction, so as to strike longitudinally, and cause a more extensive injury to the skin. When a bullet strikes the shaft of a bone, it cracks or splinters it, and either remains or passes through the cancellated ends. In its course the ball may carry before it pieces of cloth, coins, or other foreign bodies, which increase the danger of the wound. Many persons who have been shot during the excitement of battle describe the sensation as resembling the sharp stroke of a cane; but in most instances the wounded man soon begins to tremble as if in an ague-fit, complains of cold, his face becomes pale, his pulse scarcely perceptible, and he appears as if about to die. This is the condition termed *shock;* and though death sometimes does ensue during this state of prostration, it is not so serious as it appears, and the patient will probably pass out of it in a few hours with the help of stimulants and rest. Although excessive bleeding is not so common after gun-shot as other kinds of wounds, it may occur immediately to a fatal extent if assistance be not afforded. This assistance any one can give; it consists simply in placing the fingers in the wound, and if the vessel can be reached, pressing them upon it, directed to the proper point by the warm gush of the blood. Should the wound be too small to admit the finger, a handkerchief may be tied round the limb above the wound, and twisted tightly with a stick. It is well to examine the wound, to ascertain the extent of the injury done, and whether there are splinters of bone or portions of dress lying in it, which should be removed. But neither the examination nor the removal should be attempted if they seem likely to aggravate the injury. The treatment is similar to that of other wounds, and consists in protecting the part during the healing stages, moderating inflammation by a cold-water dressing and soothing poultices, and hastening the last stages of cure by the use of stimulating lotions. See *Wounds*.

GUN-SLING.—A sling for lifting a gun off its carriage, or off the ground when placed under a gin or other lifting-machine. It is formed by splicing the ends of a length of white rope together, the dimensions of the rope varying with the weight to be lifted. For very heavy guns, chain slings are used. Guns should invariably be slung as short as possible. This becomes absolutely necessary when heavy guns are to be raised, otherwise the tackle will be "chock-a-chock" before the gun is sufficiently high to admit of the trunnions clearing the carriage.

GUNSMITH.—A maker of small-arms; one whose occupation is to make or repair any small fire-arms; an Armorer.

GUN-STICK.—A stick to ram down the charge of a musket, etc.; a rammer or ramrod. This term is now rarely employed.

GUN-STOCK.—The part of a gun to which the barrel and lock are fastened. It is usually of walnut: in Europe the *Juglans regia*, in America the *Juglans nigra*. Gun-stocks, until the invention of the Blanchard lathe, were made by hand in a laborious and tedious manner. This machine was introduced into the Springfield Armory about 1820. A rough chunk of wood is placed in the first of the stocking-machines, from whence it emerges with its sides cut to the proper shape for turning. In another machine its butt-end is sawed, and a diagonal line cut at the breech. The third, armed with two circular saws, fashions the upper part of the stock in its finished form. Another machine reduces the butt to its ultimate shape. Another simply planes various places in the sides of the stock as points for the working of other machines, an operation which is known as *spot-*

ting. A sixth machine performs six distinct items, called *grooving* for the barrel, breech-pin, and tang, *heading* down, *milling*, and *finish-grooving*. The stock is at this stage prepared for the *fitting* in of the barrel. A seventh machine planes the top, bottom, and sides; while the eighth and ninth do the *shaping* and *bedding* for the butt-plates. The next machine prepares the stock for the reception of the locks. Another machine is used to cut for the guards, to bore for the side-screws of the lock, and two more to make places for tips and bands. After these various operations comes the second turning and smoothing of the work; then the grooving for the ramrod; then the boring for the ramrod from the point at which the groove ends. These machines are each provided with a pattern or templet, which is the exact counterpart of the cavity or other form to be produced in the stock. They are furnished also with cutters or borers, which, being placed above the stock, are made to revolve rapidly, and cut the wood in exact imitation of the pattern below. The movements of the tool are controlled by a guide which is inserted within the pattern. The tool is made to revolve by means of small machinery within its frame, the latter and all within it moving together with both lateral and vertical motions, being governed by the guide, which is connected with it, by the aid of very curious and intricate machinery. The work of the artisan, when the machine is in motion and the stock is adjusted in its bed within it beneath the borers or cutters, is simply to bring the guide down into the pattern and move it about the circumference and through its center. The cutting-tool follows the movements of the guide, and the result is a perfect duplicate in the stock of the form in the mold below. See *Lathe.*

GUN-STONE.—A stone used for the shot of cannon. Before the invention of iron balls, stones were used for shot, but are now altogether superseded.

GUN-TACKLE.—The arrangement of blocks and ropes for the means of raising and lowering guns. There are two of this name used in the artillery service. One consists of two double blocks, called a *gun-tackle*, the other a *heavy gun-tackle*, consisting of a double and treble block. In the former, the power is increased fivefold when the standing end of the *fall* is made fast to the movable block, and fourfold when made fast to the other. In the latter, the power increases five or six times, as used.

GUNTER CHAIN AND SCALES.—The chain and scales commonly used by military engineers. The chain is 66 feet, and its convenience in practice turns on the fact that ten square chains make one acre.

Gunter's Chain.

The chain is divided into 100 links, and thus 100,000 square links make an acre.

The name of *Gunter's Scale* or *Gunter's Lines* is usually given to three lines to be seen on almost any sector, and marked N, S, T, meaning the lines of logarithmic *numbers*, of logarithmic *sines*, and of the logarithmic *tangents*. To understand their construction and use requires a knowledge of logarithms; they are explained in every school-book of practical mathematics. The distances of the divisions marked 1, 2, 3, etc., on the line of logarithmic numbers represent the logarithms of those numbers—viz., 0, .301, .477, etc.—taken from a scale of equal parts. The other lines are constructed on an analogous plan. Calling to mind that multiplication of numbers is effected by the addition of the logarithms, division by their subtraction, involution by their multiplication, and evolution by their division, we are able to perceive with what ease many *rough* problems in areas, heights, cubic contents, and other matters may be performed through the agency of Gunter's scale.

GURGES.—A charge in Heraldry, meant to represent a whirlpool. It takes up the whole field, and when born proper is azure and argent. Also written *Gorges.*

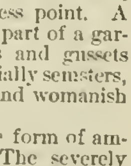
Gurges.

GURRIES.—The common name for mud-forts in India. These forts are frequently constructed near dwellings and where there is an absence of rock and

Gurry.

timber. They are quickly thrown up, and form a safe point of retreat in case of danger. The drawing shows one of these forts as constructed by General Howard on the Prairies of Idaho and Montana during the Nez Percé Indian Campaign of 1877.

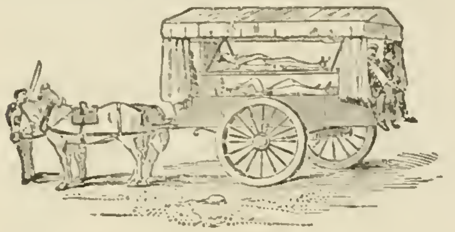
GUSSET.—1. A piece at first of chain, and afterwards of plate-armor, intended as a protection to the vulnerable point where the defenses of the arm and breast left a gap. 2. In Heraldry, the gusset is enumerated as one of the abatements or marks of disgrace for unknightly conduct. It is represented by a straight line extending diagonally from the dexter or sinister chief point one third across the shield, and then descending perpendicularly to the base. Heralds tell us that the gusset dexter indicated adultery; the gusset sinister, drunkenness; and when both were borne, it was because the bearer was faulty in both respects. Cowardice was indicated by an abatement called the gore sinister, which, though somewhat similar, we are told carefully to distinguish from the gusset, and which consists of two arched lines drawn, one from the sinister chief, the other from the middle base of the escutcheon, meeting in the fess point. A gore like a gusset represents a detached part of a garment; and according to Guillim, gores and gussets "are things in use among women, especially semsters, and therefore are fit notes of cowards and womanish dispositions." See *Gore.*



Gusset.

GUTHRIE AMBULANCE-CART.—The form of ambulance used in the English army. The severely wounded are laid on it at full length, while those slightly hurt sit in front and rear, and on the sides.

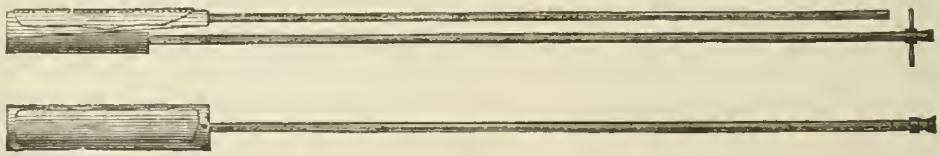
A stretcher is slung from the top for the accommodation of the former. The back-board is let down for cases requiring amputation. The hospital-chests are lashed underneath. After the battle of the Alma, in which 1986 British officers and soldiers were killed or wounded, Lord Raglan, who was almost without ambulances and draught-animals, was much embarrassed for the means of dealing with his poor suffering men; the conveyance of them down to the beach for shipment to the military hospitals at Scutari was



Guthrie Ambulance-cart.

a work of delay and misery to all concerned. Since then ambulances have been fitted up with all medical appliances, and a certain number have been attached to regiments. The latest pattern ambulance-cart in the British army is constructed to carry seven sick or wounded men—viz., two inside on the stretchers, two seated beside the driver, and three seated in the rear. One ambulance is allowed to each regiment, and fifteen to each division. See *Ambulance.*

GUTTA-PERCHA IMPRESSIONS.— Gutta-percha impressions of a portion of the bore of a gun are conveniently procured by means of wooden blocks or wedges. For this purpose two blocks are used, one about two thirds the length of the other; the longer block carries the gutta percha for the impression, the shorter one is used as a wedge. Each block has a staff longer than the bore of the gun, enabling the operator at the muzzle to place the blocks in any desired position in the bore, drive the wedge, and withdraw the blocks. These blocks are so shaped as to form an imperfect cylinder whose diameter is less than that of the bore, enabling the longer block to carry the gutta-percha to the required place in the bore. By driving in the wedge, the diameter of this cylinder is increased nearly to that of the bore; the gutta-purcha is pressed against the surface of the bore, and forced by the driving wedge to take the impression. Before taking an impression the gun should be thoroughly washed out and oiled with a well-oiled sponge; the gutta-percha, softened by hot water, just below the boiling-point, to the required consistency—about that of putty—is then placed on the block, well oiled, worked and kneaded with oil until it is spread over the required portion of the block. The blocks are also well oiled, particularly the surfaces which come in contact. The two blocks are put together at the muzzle, and both together are pushed into the bore to the distance desired, marked on the staff of the carrying-block. The carrying-block is held steadily by its staff, while the wedge-block is driven in by several blows of a sledge on the end of its staff; from two to five minutes is sufficient to allow it to set. The wedge-block is withdrawn first and the carrying-block with the impression afterwards. To withdraw the wedge-block, an iron pin is run through the staff near the end, and struck with the sledge until it starts, when it is easily withdrawn. The carrying-block will generally fall or release itself by its own weight, bringing the impression with it, if the impression is taken anywhere in the upper half of the bore. Where an impression is wanted from the bottom of the bore, a small block or rider is pushed in at the same time as the carrying-block, so as to keep the gutta-percha from touching the surface of the bore while being pushed into place. Afterwards the rider-block is withdrawn, the wedge driven in, and after the wedge is withdrawn the rider-block is pushed back close to the carrying-block, and acts as a fulcrum by which the impression is raised free from the bore, when both may be withdrawn together. In taking an impression on the side, it is better to push in the blocks as in taking the impression above, and then to turn the blocks to the side. Unless the block under the gutta-percha is well oiled, some difficulty may be experienced in releasing the impression from the block. The carrying-block should have a slight raised edge on each side of the upper surface of the block, to prevent the gutta-percha from spreading out too much when undergoing the pressure from the wedge, and also to protect it when turning the blocks for a side impression. Impressions are marked by their distance from the muzzle in inches; the name, number, and caliber of the gun, and whether taken at top, bottom, right, left, top right, top left, bottom right, bottom left, of the bore, when facing the muzzle. A convenient size to obtain the gutta-percha is in slabs twenty inches long, five inches wide, and five eighths of an inch thick. Each slab will make, ordinarily, two or three impressions, and can be used several times if desired. The defects are noted in the following manner: The distance is recorded in inches from the muzzle, and the position around the gun is recorded in every case according to the diagram, looking from the muzzle, as "up," "D," "R," "L," or in intermediate positions, as "R of D," "L of up," etc., etc. If a defect extends any length, it is noted as in the following examples: "36 inches, D to L," which means defect thirty-six inches from the muzzle going round the bore from "down" to "left;" or "49 inches to 56 inches up," meaning a defect running along the top of the bore from forty-nine inches to fifty-six inches; or, what is the same thing, seven inches long.



See *Impression-taker*, *Inspection of Ordnance*, *Ordnance*, and *Vent-impressions*.

GUTTE—GUTTY.—A term in Heraldry, from the Latin *gutta*, a drop, said of a field, or any particular charge on the field, covered with drops. When the drops are red, they are supposed to represent drops of blood, and the bearing is said to be *gutté de sang*. In this case some great suffering or labor, such as fighting for the recovery of the Holy Land, is indicated. Where they are blue, again, they represent tears, and the bearing is said to be *gutté de larmes*. When white, they are called drops of water, and the bearing is described as *gutté de l'eau*; but Nisbet is of opinion that tears are intended in this case also, and that repentance or penitence is signified by both.

GUTTERING.—The scoring or erosion observed at
